trict produced 585,408 tons of concentrating ore yielding an average of 2.2% copper and 122,702 tons of smelting ore yielding an average of about 9% copper. The Old Dominion smelter was the only reduction plant operating in the district during the year. The district is served by the Gila Valley, Globe & Northern railway, a branch of the Southern Pacific. The Old Dominion and the United Globe mines were the largest producers during the year. The average grade of ore mined and treated by the Old Dominion company for the past two years is shown below. Grade of ore mined and treated by Old Dominion company, Arizona, in 1911:

	Percentage of copper.	
	1911.	1910.
Average smelting ore .....	7.75	7.85
Average concentrating ore .....	3.50	3.49
Average of ore mined and treated.....	5.84	5.70

The average cost of refined copper for the year was 9.15c. per pound. The United Globe mines produced 110,578 tons of ore, yielding 8,523,433 lb. of copper, 11,459 oz. of silver, and 875.9 oz. of gold.

In the Miami end of the district the Miami and Black Warrior mines were the only important producers. The Miami Copper Co. began production in 1911, the first unit of the mill going into operation March 15. At the close of the year five units were in operation, and the sixth was nearly equipped. The entire plant will have a capacity of about 3000 tons per day. The result of milling operations for the year are as below.

Milling operations of Miami Copper Co., Arizona, in 1911:		
Ore milled, tons .....	445,036	
Percentage of copper in ore.....		2.48
Concentrate produced, tons .....	20,065	
Percentage of copper in concentrate.....		40.36
Copper in concentrate, lb.....	16,195,561	
Copper recovered per ton of ore, lb.....		36.39
Mill extraction, per cent.....		73.37

From the concentrate produced, the net returns of refined copper amounted to 15,385,783 lb. Based on the net production, the cost of copper in concentrate on board cars at Miami was as follows:

	Per ton of ore.	Per lb. of copper.
Mining .....	\$1.2134	\$0.03500
Milling .....	0.6274	0.01810
General .....	0.1706	0.00492
Total .....	\$2.0114	\$0.05802

The concentrate is shipped to Cananea, Mexico, for treatment. The main work of the year underground was confined to preparation for and extraction of ore, but little prospecting of unexplored territory was accomplished. At the close of the year ore reserves were estimated at 18,232,000 tons, averaging 2.58% copper. In 1912 the Inspiration Consolidated Copper Co. was formed as a merger of the Inspiration Copper Co. and the Live Oak Copper Co. It is reported that this company has about 45,000,000 tons of ore developed of an average grade of about 2% copper. Blocking out of the ore was continued through the year and plans were inaugurated for the construction of a mill to treat the ores. Development work was carried on by other companies in the district.

#### MINERAL CREEK OR RAY DISTRICT

The Mineral Creek or Ray district began important production during 1911. The output for the year was about 15,700,000 lb. This was the first important production of copper from this district. The disseminated deposits occur in crushed schist and granite. The original mineralization was pyrite and chalcopyrite, but the commercial ore has resulted from secondary enrichment of the deposits produced by the leaching of the copper minerals from the upper portion and redepositing them as chalcocite on the sulphides lower down. This has resulted in a blanket-like deposit of commercial ore covered by a relatively barren

capping and underlain by a zone of original mineralization too low in copper content to be of commercial value.

The average thickness of the leached zone in the Ray Consolidated ground is 252 ft., and the average thickness of the ore 101 ft. Locally, especially associated with the diabase, native copper becomes of some importance. The district is served by the Arizona & Eastern railroad. The mines and reduction works are connected by the Ray & Gila Valley railroad, controlled by the Ray Consolidated Copper Co. The most extensive operations in the district were conducted by the Ray Consolidated Copper Co. The underground work of the year was largely confined to preparation for the mining and extraction of ore, little attention being given to prospecting undeveloped territory. At the close of the year the ore reserves were estimated as follows: Fully developed by churn-drilling, 64,700,000 tons, having an average grade of 2.16% copper; fully and partly developed, 77,314,470 tons, having an average grade of 2.17% copper. The shrinkage stope system of mining has been applied in two portions to the property and is reported to be entirely satisfactory.

The first unit of the concentrator at Hayden was put in operation in March, and at the close of the year five units had been completed. The plant is to consist of eight units with a nominal capacity of 8000 tons of ore per day. The total ore treated for the year was 681,519 tons, of an average grade of 1.83%, resulting in a gross output of copper contained in concentrate of 15,721,520 lb. and corresponding to an average extraction of 63.1%. In the latter part of the year the extraction was considerably above the average, being 67.38% for December. The average assay of concentrate produced was 22.4% copper. The average cost per pound of copper produced to the close of the year was 10 $\frac{3}{4}$ c. This cost was much higher than will be normal. Early in 1912 the cost was reported at 9c. per pound, and the management estimates that when the plant is in full operation the cost will not exceed 8c. per pound. The concentrate was shipped to El Paso during 1911, but early in 1912 delivery to the Hayden plant of the American Smelting & Refining Co. was begun. Early in 1912 controlling interest in the Ray Central Copper Co. was acquired by the Ray Consolidated Copper Co., and the properties will be operated together.

#### SILVERBELL DISTRICT

The Silverbell district of Pima county made practically no production of copper in 1911. It produced about 5,750,000 lb. of blister copper in 1910, as compared with about 10,500,000 lb. in 1909. Important copper production began in the district in 1904, though it had produced some silver and a little copper before that date. At the close of 1911 the district had yielded about 41,800,000 lb. of copper.

Paleozoic sediments have been intruded by an acid porphyry, the sedimentary formation for the most part being detached blocks entirely surrounded by porphyry. The copper deposits are of two types—contact deposits, in which the sulphides of iron and copper, together with contact silicates, garnet, epidote, etc., have replaced limestone; and disseminated deposits, in which the original ores consist of iron and copper sulphides as veinlets and small grains in the shattered porphyry. The commercial ores of the latter type in this district, as in most others, have resulted from the secondary enrichment of these deposits.

The ore mined to the present time has been principally that of the contact deposits. These ores are in general rather low-grade smelting ores. However, they are nearly or quite self-fluxing and can be treated cheaply. Development of disseminated ores has been in progress by several companies and encouraging results are reported, but there has been no important output from this type of ore. The ores of the district are treated at the plant of the Southern Arizona Smelting Co., at Sasco. This plant was closed down August 16, 1910, and has remained idle since. A branch of the Southern Pacific railroad extends from

Red Rock to the district. The Imperial Copper Co. has been the main producer in the district.

#### OTHER DISTRICTS

Shipments of ore were continued for the Turquoise district, Pinal county, the output for the year being about 3,300,000 lb. of copper. The Paleozoic sediments of the district have been extensively faulted and intruded by monzonitic porphyries. The copper deposits of the district may be grouped as follows:

(1) Oxidized blanket deposits connected with thrust faulting, exemplified by the orebodies of the Germania and Mary mines. (2) Pyrite deposits with some associated bodies of oxidized ore in the Cambrian dolomitic limestone and shale, exemplified by the Mame and Leadville mines. (3) Pyrite deposits with associated bodies of oxidized or enriched ore in Carboniferous limestone, exemplified by the Copper Belle and other mines near Glee-son.

The Big Bug district of Yavapai county also contributed considerably to the copper output.

### Mine Rescue Work

The following outline of the conditions to be observed in the conduct of mine-rescue work was adopted at the National Mine Rescue Conference held at Pittsburg, September 25, 1912. The conference further resolved that in rescue work untrained men should not be permitted to use breathing apparatus except when it is the only possible chance to save life. In selecting untrained men, discipline is of equal importance to training.

#### OUTSIDE ORGANIZATION

1. All openings to be carefully guarded.
2. There should be a man in charge of outside arrangements to see that ventilating appliances are put in condition for operation, so as to be ready to operate when conditions require it.
3. See that good, competent men are placed at all openings to the mine and that they obey the orders given.
4. A competent person to be placed near the entrance to the mine to examine all safety lamps before they are allowed to be taken into the mine.
5. Some specified person to be placed at the entrance to check off all persons and make a record when they go into and come out of the mine.
6. Proper provisions to be made in the way of food and shelter to take care of persons engaged in rescue work.
7. A physician to be on hand while rescue parties are in the mine.
8. Safety lines to be established around all openings inside of which lines no open lights should be allowed.
9. A man in charge of the rescue squads to organize and have them ready to enter the mine when called upon.

#### INSIDE ORGANIZATION

1. A man to have full charge of the inside operations on each shift.
2. An advance squad under a competent leader to explore the workings in advance of the other squads who are advancing the ventilation, making repairs, and the stretcher squads.

The squads are to advance in the following order:

- a. Breathing apparatus or advance squad.
- b. Stretcher squads.
- c. Temporary ventilation squad.
- d. Material squad.
- e. More permanent ventilation squad.
3. A station to be established at a point suitable as a base of operations from which to work, and with a competent person in charge who should re-examine all lights before they pass beyond him to the interior of the mine.
4. A telephone should be established at this station to communicate with the surface, and to be carried into the workings as fast as possible.
5. No person to go in advance of the ventilating cur-

rent except the advance squad, which shall make an examination of the atmosphere for gas, and examine the return air-current frequently for indications of fire; also for any other dangers which are likely to exist.

6. A doctor should be stationed at this inside station with necessary supplies for his use.

7. While advancing into the mine all unexplored openings to be endangered off.

8. Strict discipline to be maintained at all times.

### Gold-Mining in Kyushu

Gold-mining in the island of Kyushu, Japan, during 1911 showed a very fair increase (9600 oz. troy) over the output for the previous year, due to the general development of the mines with modern machinery. The Hasami gold mines in Nagasaki prefecture installed some modern machinery about two years ago and increased their output for 1911 (which amounted to \$77,400) by about 50% over that of the preceding year. The Taiono gold mines in Oita prefecture produce about 2400 oz. per year, the Urushi mine in Kagoshima prefecture 1200 oz., the Okuchi and Ushio mines in Kagoshima each about 4800 oz. per year. The Yamagano gold mines in Kagoshima prefecture are the largest producers of this metal in Kyushu, their annual output averaging over 15,600 oz. The Serigano gold and silver mines, in the same prefecture, are also showing increased production, their output being over 6000 oz. per year. The Kushikino gold and silver mines, in Kagoshima prefecture, which were taken over and are being developed by the Mitsui Bussan Kaisha, are showing good results, and with the installation of modern machinery, which is being ordered from the United States, this group of mines will probably be one of the best gold producers in Japan, the estimated output being placed at 2400 oz. gold and 18,600 oz. silver per month. The first installment of machinery has been ordered from the Dorr Cyanide Machinery Co., the Allis-Chalmers Co., and the Moore Filter Co., and more will be ordered as the development work progresses. Considerable interest has lately been centred in a new gold-mining district in the north-central part of Kyushu, near Kitakawachi, Fukuoka-ken, where some prospecting has been done and samples yielding nearly 1 oz. per ton have been brought in.

### Use of Sand

When a new sand is to be used in mortar or concrete work it is best to test it first in a sample block, and see the results, before using on a large scale. A mixture of coarse and fine sand with the coarse predominating is best, as it makes a denser and stronger concrete than a coarse-grained sand with the same amount of cement. This is because the small grains fill the voids made by the large ones. A sand with more than 45% voids should not be used, and it is always best to know the amounts of voids in the sand that is being used. This can easily be determined by taking the weight of a cubic foot of the sand and multiplying it by 100 and dividing by the product of the specific gravity into 62.5, the weight of one cubic foot of water. The result subtracted from 100 will give the percentage of voids.

$$\text{Percentage of voids} = 100 - \frac{100 \times \text{weight of cu. ft.}}{62.5 \times \text{sp. gr.}}$$

The less the percentage of voids the better the sand.

IMPORTS of pig iron into Japan from the new Tata iron furnaces in India have been very large, and to a certain extent have driven English pig iron from the market. The Mitsui Bussan Kaisha has been a large buyer, both for its own account and also for the government iron works at Wakamatsu. Although the quality of the Indian iron is very much inferior to that of the English, or even of the Chinese formerly imported from the Han-Yeh-P'ing works, importers have the advantage of \$2.50 per ton in freight.

## Discussion

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment. Insertion of any contribution is determined by its probable interest to the readers of this journal.

### Persistence of Ore in Depth

The Editor:

Sir—In a recent issue T. A. Rickard has crystallized current opinion on this subject in a stimulating article that will meet with general acceptance. Briefly stated, his conclusion is that after the oxidized zone and the zone of secondary sulphide enrichment are passed, ore deposits must be expected to become leaner with increasing depth. Generalizations are notoriously dangerous, and are never more so than when applied to the study of ore deposits; few sciences indeed have suffered more in this respect. Details that have been garnered from the study of a given metalliferous deposit, and that might have had a real value when applied to the construction of a sound theory of deposition for that metal alone, have been ruthlessly transferred to stay and brace the tottering structure built for another metal of possibly the slightest genetic affinities. When all the known facts concern-

FIG. 1. A, UNFAVORABLE ROCK. B, FAVORABLE ROCK.

ing the deposition of any one metal have been collected, collated, and analyzed, then, and not until then, may analogies be made with the data of another metal, similarly treated. Meanwhile, further theorizing is as the cloud of dynamite smoke from an intermediate winze when already the distant plumb-line is with difficulty discernible through the telescope.

Frankly I regard Mr. Rickard's generalization that ore-channels must become leaner in depth as pernicious doctrine if universally applied; the more so, in that for most orebodies it contains a kernel of truth. It is indeed entirely true when its application is limited to a certain group of orebodies, namely, to those formed near the existing surface. This group includes, it must be noted, not only deposits formed in recent geological ages, but also some of Paleozoic and pre-Cambrian times. In the latter cases subsidence and burial beneath later deposits have protected the upper portions of these ore-channels against the erosion of ages. The auriferous conglomerate of the Witwatersrand may, with some reason, be regarded as a specific instance. In all these cases the general reason for ore deposition is probably the cooling of rising solutions on approach to the earth's surface; local modifications arise from variations in physical and geological structure.

But there are many deposits that cannot be ascribed to simple cooling. These occur chiefly in Archean and Paleozoic rocks, though, as in the Mother Lode-Alaska Tread-

well belt, they may occur in Mesozoic strata. Lode-fissures in these rocks are normally very steep, while, from the vicissitudes they have undergone during a large portion of geological history, the strata are usually much disturbed. It is a fundamental axiom that in these older deposits the nature of the lode-wall exercises a vital influence on the richness and sometimes on the mineral character of the orebody. Hence it rarely happens that a great depth is reached before the lode, worked from the outcrop downward, has passed out of the favorable rock. Herein lies the kernel of truth in Mr. Rickard's generalization, but surely the fact should be stated in terms of geologic structure and not of depth.

The point is perhaps best illustrated by sections of actual occurrence obtained in the course of examinations made during the past few years. The sections and descriptions are admittedly generalized for a twofold reason: this note is written far away from notebooks and from the literature of the subject, and the reports from which the sections are taken are not yet freed for publication.

A generalized section of an area quoted by Mr. Rickard

FIG. 2. A, UNFAVORABLE ROCK. B, FAVORABLE ROCK.

as affording satisfactory evidence in support of his proposition is shown in Fig. 1. The favorable rock (B) is inclined at  $65^\circ$ , the lodes are vertical and carry ore only when in the favorable rock. It is evident that the result of work on No. 1 lode has completely supported Mr. Rickard's argument; indeed, I suspect that it was on the evidence from this lode that his argument was based. But No. 2 lode has not appreciably diminished in value in depth. On the contrary, one of the best levels in the mine was below the 2000-ft. level; No. 3 lode (as yet explored only near the surface and proved to exist at 2000 ft.) was poor at the surface in unfavorable rock (A), but it is anticipated that it will materially improve at 2500 ft., when it will reach the favorable rock. Of course, it has yet to be shown that it will yield ore. It is, therefore, evident that the factor of depth postulated by Mr. Rickard is not the dominant factor in the area cited.

Two of the most famous instances of occurrence that confirmed miners of forty years ago in their belief that ore-channels might increase in value with depth are illustrated by Fig. 2 and 3. They are sufficiently self-explanatory. Fig. 2 is well known. Fig. 3 has, I believe, never before been published, yet the result, though not the reason, has been quoted by a generation of miners in favor of deeper sinking. Both these cases are covered by Mr. Rickard in his summary of the causes that lead to the belief in increasing richness in depth, and they are reproduced

here to show that the old miners merely fell into precisely the same error with regard to these deposits that Mr. Rickard himself has fallen into in regard to the area in Fig. 1; they assumed that depth and not geological change was the controlling factor that affected the richness (or poverty) of the orebody.

The famous Oroya 'shoot' or 'pipe' at Kalgoorlie 'petered out' in depth, but depth *per se* had nothing to do with its disappearance. It was deposited under a geologic cornice (for want of a better word) formed by lateral displacement along a fault-plane. Its foot-wall was another, generally parallel, fault-plane. But when these two came together, as they occasionally did, ore failed until they again separated. The Oroya pipe was the mainstay of the eastern side of Kalgoorlie, and its disappearance has had much to do with the falling yield of that goldfield. Instances could be multiplied indefinitely from these older rocks to show that the failure of ore is due to a change in the geologic conditions; I can, on the other hand, recall no instance in homogeneous country where failure of ore could unhesitatingly be ascribed to increase in depth. Mr. Rickard mentions the famous Champion Reef of Kolar, India, now working at a maximum depth of 3900 ft., in terms that show his scepticism of its persistence. But if it should fail at greater depths it will fail not on account of the depth, but because the fissure has passed from hornblende-schist into the granite, and so far as I know

FIG. 3. LONGITUDINAL SECTION ALONG VEIN, SHOWING SHAFT SUNK 600 FT. IN THE VEIN BEFORE MEETING ORE. THE SHAFT WAS SUNK LONG BEFORE THE CONTINUITY OF THE ORE-SHOOT WAS ESTABLISHED. ORE OCCURS ONLY ABOVE THE FAULT-PLANE.

there is no evidence to indicate such a change is likely to take place. Naturally lodes of this character must always be few in number, because, as already pointed out, it can rarely happen that a fissure will remain in the same country rock to great depths. This is particularly so in Archean rocks. To the mining engineer, and even to the geologist unaided by the microscope, the majority of Archean rocks, especially in a differentiation series, look much alike. Yet in a metamorphosed and chloritized quartz-dolerite, I have known not one but many instances of ore failing in a strong lode when the only observable change in the rock in thin sections was an increase of hornblende from 5 to 15%. Lodes that have not depended on cooling for their filling are clearly peculiarly susceptible to the influence of the wall-rock. And if such a small change as the foregoing correlates poverty of ore, it is not wonderful that the passage in depth from, say, a quartz-diorite into a hornblende-porphyrite may betoken the complete disappearance of ore. Yet these two rocks may be so much alike in the Archean complex that no geologist could distinguish them in hand specimens. It is therefore not surprising that the mining engineer, failing to recognize the change, must of necessity ascribe the poverty of his bottom levels simply to increasing depth.

Putting the maximum depth of mining at 7000 to 8000 ft., not for reasons of ventilation or of hoisting, but for another that is never discussed in the press or with the man in the street, and among mining engineers is spoken of only with the greatest caution, I find myself prepared,

when considering the depth to which these deeper-seated ore-channels may go, to subscribe to the words of W. P. Blake (quoted by Mr. Rickard) merely italicizing one word, "whatever view we may take of the source of the mineralization of lodes, we may conclude from the evidence that it is deep-seated; and in a *homogeneous* country rock may be expected to extend as far as we can ever reach downward in mining operations."

A characteristic feature of Archean or channels mentioned by Mr. Rickard, is a horizontal zoning in the orebody. There is no visible change in the rock and no pinching occurs in the lode to account for the peculiar distribution of the valuable ore. It is so marked in Kalgoorlie that in certain mines the driving of a level in poor ore causes the manager no perturbation. He knows that his leading stope, when broken out, will bring the whole to the run-of-mine grade. Despite, or perhaps because of, my initial disclaimer against theorizing, a vague speculation as to the origin of this zoning may be permitted. It always recalls the successively lower marks made by waves of the ebbing tide against a sea-wall. In this case it may also represent successive high-water levels of a flowing tide. To be associated with this phenomenon is a separate conclusion that metalliferous deposition in deep-seated regions is paroxysmal in character, comparable in many respects to volcanic outbursts at the earth's surface.

The question of the behavior of lodes in depth is one of vital importance to the miner of the future. Most mining engineers are aware of the immense amount of capital annually expended in the search for metal mines. From Spitzbergen to Tasmania, from Nikolaievsk to Puntas Arenas, the 'scout' is ubiquitous and the return for it all is lamentably small. H. C. Hoover has recently shown that the outlook for new goldfields is not cheering, and

FIG. 4. LONGITUDINAL SECTION ALONG A BROAD ORE-CHANNEL, SHOWING A BARREN OUTCROP AT A, ON WHICH SINKING MIGHT REASONABLY BE ADVISED WITH THE EXPECTATION OF FINDING ORE IN DEPTH.

with his conclusions I find myself in complete agreement. The same conclusions may probably be reached for most of the baser metals. Despite the great price of tin and the increasing demand for it, occasioned by the oil and canning industries, no new tinfields of importance are known, nor is there any whisper of any. We are therefore forced back upon the old fields. The outcrop mines are there known, and either have been exhausted or are being worked. Future industry must more and more concern itself with concealed orebodies; it is here that a universal acceptance of Mr. Rickard's proposition would prove exceedingly harmful both to the mining engineering profession and to mining capital, already greatly restricted in its search for profitable investment. I have, for example, in mind an area shown in section in Fig. 4 in which it might be sound mining business to sink on a poor lode at A (if any such were known) with a reasonable expectation of an increase in the value of ore at depth. It is obvious that speculative search of this kind could only be advised after the most careful investigation and also when the financial interests had been fully acquainted with the character of the enterprise.

Finally, while I disagree with Mr. Rickard on the question of terms, it is clear that the result reached is much the same, namely, that it is a dangerous and often a fatal policy to regard the unexplored lower levels of mines as being likely to produce as much ore as the upper levels. There are notable exceptions, but they are few.

MALCOLM MACLAREN.

Liskeard, Cornwall, September 15.

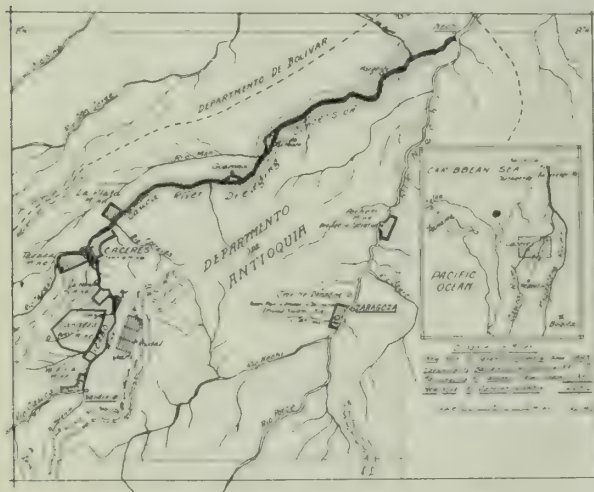

## Mining Conditions in Antioquia, Colombia

The Editor:

Sir—After traveling over the entire mining district of Antioquia, Colombia, South America, I find that the benches, bars, and high ground where water could be brought from a reasonable distance have all been worked by the Spaniards years ago, and worked over by the natives more recently. The entire country is plentifully sprinkled with old worked-out diggings. Most of the alluvial deposits are low and only suitable for elevating or dredging. Along the rivers the valleys are broad and very flat. This condition of the country makes it very difficult to bring water with sufficient pressure to work the ground, and necessitates long and expensive pipe-lines. A three to five-mile ditch is considered quite long, and owing to the softness of the soil and tropical rains, the expense of repair on a long ditch is tremendous.

Antioquia is undoubtedly a rich country in minerals. Most of the streams carry gold in quantity that in California would be considered profitable to work. The prin-

cipal work on *playas* is done during the dry season, for during the rains the rivers rise and flood the machinery, so that it is not only difficult but dangerous to work. In the dry season the rivers are very low, and the small creeks are almost dry, so it is necessary to have a substantial water right, which means long ditches before it is possible to work with a small plant. Owing to the thick jungle, rough country, and bad climate, prospecting is difficult, and transportation expensive. The richest mines are usually in districts where conditions are most unfavorable.

This is nothing compared to the trouble a foreigner encounters in trying to lease, buy, or even denounce a mine. The ignorance of the Antioquianos concerning mining valuations is ridiculous. They expect a foreigner to pay a fabulous price for a claim that has never been prospected or worked. Should you denounce a mine, equip it, and they see you are making money, they will immediately tie you up in a lawsuit and swear that some one or other of their relatives owned it years ago. Clear titles to property are almost impossible to secure. The natives ask you whatever price their fancy dictates for almost any property. All the mines are usually owned by several shareholders, and if you wish to buy or lease one, you will find it utterly impossible to get all these shareholders to agree to any reasonable proposal. The natives require several weeks to transact a small piece of business that any ordinary person could do in a day or so.

The cost of living is extremely high, and traveling costs a small fortune; for one must have saddle-horses, pack-mule, and a peon to attend them. The royalties for leasing a piece of property are high, being always from 20 to 30%, including very hard conditions. My advice to miners who wish to do any prospecting or investing, is to steer clear of Colombia and go to the North or Canada, where one can find a healthy climate and be protected by

good laws. Almost every foreign prospector or miner on a small scale who has invested money in Colombian mines has failed to make a profit.

LOUIS A. MAIRE.

Visalia, California, October 15.

## Placing Shaft-Sets

The Editor:

Sir—In a small—say a 2-compartment—shaft, I find that the quickest way to timber is to work, when possible, from the bottom upward, dispensing with hangers. Be careful to keep powder away from the walls, and keep them solid; a double jack is better than a pick for this. See that the 'muck' comes out of the bottom and not out of the sides. Any wall which sounds 'drummy' must be either taken down at once, or watched carefully every shift; use the same men as much as possible from start to finish. Any bumps or corners that are too close can be removed better by plugging with uppers when the bottom is down a few feet, and these plugs must be 'spit' before the bottom holes, so the fuses do not cut off. I cut all fuses the same length; with one man firing slowly, it is possible to tell which hole misses, if any. In a wet shaft cut the fuses different lengths and tie the ends together with wire in a bunch; hang them with a wire to a nail in a crack or wooden plug, and put a handful of oily waste in the centre; set fire to this and pull out. A sinking ladder is useful; although rarely used by the men, it gives confidence when shooting. An old 1/2-in. wire rope will do for the sides, and rail straps in pairs serve as rungs. One strap is bent over 3/8 in. on each end and the bolts tightened; to prevent slipping, drive a horse-shoe nail through the rope under each rung and double over. You thus have a ladder that lasts well, works fine, and costs little. Some drill holes in the side, put a few slivers of wood in them, then drive in old drills; these serve to steady the ladder. Often a pair of drills may serve in this way as a stirrup for a stull in an awkward place, saving a hitch, and will bear more weight than the stull will. If possible, go down 50 ft. without timber, then throw two stulls across the narrow way of the shaft, plumbing them carefully. These stulls can be two inches wider than the sets, giving a sill for the lagging. Then timber to connect with the last stulls. The working platform is carried up from set to set, and the bobs, being from the inside corners above and in the clear, make mistakes impossible. This is a fast way of timbering, and for repair work or taking out timbers later these stulls are invaluable and help to strengthen the timbering. A good way to hold up the 'shooting set' against the stulls and last set is to use short chains thrown around the set and the end link put through a link and held with a mule-shoe. Often, by being careful with the powder in sinking, much lagging can be dispensed with. A coat of whitewash in a dry shaft is helpful, as the candles give more light and there is less danger of fire, and it perhaps helps to preserve the timber. Also when lagging is not used, and the walls are whitewashed, you can tell at a glance where rock is loosening. Stations are also improved by this procedure. As to timber framing, when using round timber, which is often the only kind obtainable, square only the upper side and inside of the sets. A pair of sawhorses with a strap like a windlass brake to button down and keep the stull solid, is a good arrangement. Frame one end, then level it carefully; now, with the level, mark a working line on the other end and the twist is taken out of the timber. A good rip-saw works cleaner and faster than a chisel. Fit all sets on the surface and mark them. There is a swivel bucket-hook advertised which, it is claimed, keeps the bucket from turning when sinking with a crosshead; this must be a great help, as the crosshead is left at the end of the guides; the rope, running through a piece of pipe in the centre, will often cause trouble by making the bucket revolve, especially when the rope has been strained a little.

La Caridad, Nacozari, October 7.

AN OLD MINER.

### NEW YORK

THE METAL MARKET.—MEXICAN COMPANIES.—DIVIDENDS.

A severe break in the London metal market—£3 15s. per ton—as a result of the crisis in southeastern Europe, while it created a great deal of discussion, failed to have any effect upon the New York quotations for copper. The Balkan outbreak has, outwardly at least, rather stiffened the holders of copper in their attitude, and the claim is made that in the event of the larger nations of the Continent being drawn into conflict there would immediately arise a demand for copper that would take every available pound in the world's visible supply, and that without much regard to price. How far the demand which has made Germany so great a consumer during the past three years is due to preparation for war is not a matter of public knowledge, but there can be no doubt that this element was and is very important in Germany. While the copper market is being carefully watched and the outlook studied from every possible angle, business remains quiet. Eastern financial centres are nearly always waiting for something to come to pass, and at this time the stock markets seem to have settled down for the pre-election wait, and all matters that can be postponed until November 5 are going over until that time. The strike at Bingham is apparently no longer a factor in copper-metal prices, and it is only a question of a little time when production will again be normal.

The position in the lead market is interesting, as it is conceded that stocks are low, both in the hands of the producers and the consumers. The users of lead are doing an increased business. Paint manufacturers are all busy, and the recent abnormal activity in public utilities has given rise to an unprecedented call for lead-covered cables, miles of which are drawn through the underground pipes in those cities that have forced telegraph and telephone wires to be laid underground. The American Smelting & Refining Co. has, in a way, been 'holding the umbrella' for the lead producers. The whole situation is such that a sharp advance in price would be only natural and a squeeze as a consequence something more than a mere possibility.

It has been so long since the New York traders have had a chance to welcome a new, real copper promotion that any tidings in this direction are considered good. It is hoped that Thomas F. Cole's new organization, the Rainbow Development Co., will seek a market in New York rather than in Boston. There are some things which seem to conspire to keep the mining-share market in New York nearly down to the vanishing point. In the first place, some of the best issues, including practically all of the Guggenheim enterprises except Braden and the newest addition, the Alaska Gold Mines Co., have been taken from the Curb to the floor of the Stock Exchange, with the result that trading has dwindled rather than otherwise. Traditions of the Stock Exchange are obdurate toward all mining ventures. Of the remainder, the Cobalt shares have practically ceased all activity. Goldfield Consolidated has evidently almost reached the end of its productive career as a high-grade gold mine. The New York market for Tonopah stocks has long been a secondary one, the orders for the greater part originating in Philadelphia and Pittsburg, principally the former. The Heinze shares (Ohio, Davis-Daly, United Copper, and Stewart) have suffered on account of the troubles and doings of F. Augustus Heinze. Some of the companies, as in the case of Davis-Daly, have cast Heinze into the outer darkness. In the case of the Stewart the attempt was unsuccessfully made. In this property Heinze has found another opportunity to indulge in his favorite pastime of legal tangles. The Stewart is now involved with the Ontario in an apex fight, while the Bunker Hill & Sullivan is after the Stewart, with a claim for ore mined through the Stewart work-

ings from the Saxon claim. There are people in Butte who will say that this is by no means the first time that such an accusation has been brought against F. A. Heinze.

The British Columbia Copper Co. is to emulate its larger neighbor, the Granby, in increasing its holdings. Some months ago the company took a 'working option' on the Silver Dollar and the Ada B. claims in Copper Mountain, British Columbia. The exploratory work which has been done revealed a showing sufficiently favorable to justify making the first payments required. The remainder of the purchase price is spread over a long period of time and payments are to be made out of the earnings of the properties. The British Columbia also has options on the Voight holdings, which adjoin the newly acquired claims.

Notwithstanding conditions in Mexico, which apparently grow worse instead of better, mining operations are carried forward in El Oro without cessation. The El Oro Mining & Railway Co. reports operation of the mill for 29 days during September, treating 19,210 tons of ore and 15,910 tons of tailing, yielding bullion valued at \$168,530. Operating expenses were \$90,660, expended on development \$24,130, total expenses \$114,790, leaving a

BUNKER HILL & SULLIVAN MILL.

profit from mining operations of \$53,740. The profit derived from the operation of the railway was \$8140, making a total profit of \$61,880, and \$8000 was expended on permanent mine improvements. It has been many months since any effort has been made to enlist the public's capital in Mexican mining ventures. The Puebla Smelting & Refining Co., however, has just been listed on the New York Curb, and is to build and operate a smelter in the Magistral mining district in the state of Puebla. The claim is made that the company owns a large acreage of coal lands and fluxing material to operate a 500-ton custom smelter. It is stated that the machinery for the first half of the plant to be erected is already on the ground. The shares are now being traded in 'when, as, and if issued.'

Mining dividends continue to be the most interesting feature of the present situation. The Hollinger, which with the Dome divides the honors in Porcupine, has declared an initial dividend of 3%, payable November 2. This is the first money to come back out of mining operations in Porcupine and is but a drop in the bucket compared with the amounts that were sunk in claims at extravagant prices when the excitement was at its height. The Coniagas mine, at Cobalt, is to pay 12% on November 1. This is a regular 6% quarterly dividend, an extra dividend of 3%, and a further extra dividend of 3% which was to have been paid in May last, but distribution of which was temporarily deferred. It is a good indication when the investor begins to study the returns from such properties as the low-grade gold mines of Alaska, the Bunker Hill & Sullivan, and the Hecla in Idaho. Bunker Hill & Sullivan has paid more than two and a half millions in dividends, and is now paying 2½% per month regularly, with extra dividends at the end of each quarter. The Centennial-Eureka, which is owned by the United States Mining Co., has paid its second dividend of \$1.50 per share for the current year. The Centennial-Eureka has

a capital of 100,000 shares, of which all but 136 shares are owned by the United States Mining Co., a subsidiary of the United States S. R. & M. Co. At the meeting of the Amalgamated Copper Co. held this week the board of directors acted as was anticipated and declared a quarterly dividend of  $1\frac{1}{2}\%$ , placing the stock on a 6% basis.

### LONDON

PROGRESS AT THE GEEVOR. TIN MINING BOOMING.—DEVELOPMENT IN BOLIVIA.

Last week I wrote about the boom in Cornish matters and mentioned that many well known American engineers have recently taken solid interests in the old county. Since then details have come to hand relating to the results at Geevor, a mine near Land's End having the Levant and Botallack mines as neighbors. This old mine has been reopened under the direction of another American engineer, R. Gilman Brown. The progress has been steady and sure, and the proportional distribution of work above and below ground has been well balanced. Operations were started in 1906 and exploration work was carefully conducted before any surface plant was provided. Subsequently 20 stamps and a dressing plant were erected. The later developments have been so satisfactory that the mill is to be extended so as to treat 100 tons per day, together with additional plant intended for the improvement of the extraction. Further capital will be required to complete the new outfit and to continue sinking and development. As a rule, Cornish managers do not commit themselves to any statement relating to ore reserves. Probably Edward S. King, now manager of Carn Brea & Tinerof, late of West Australia, was the first to say, though guardedly, what were the definite prospects for the future. Mr. Brown has gone farther, and states that 60,000 tons of ore has been proved at the Geevor above the fifth level, having a recoverable content of 30 to 35 lb. black tin per ton; also that on the fifth level the ore-shoot has been exposed for 1300 ft. During the past year the extraction has been about 23 lb. of black tin per ton, but the additional plant is calculated to improve upon this by 5 or 6 lb. per ton. Another interesting point in connection with the report is that a plan of the workings is given. This is another innovation and an example which other Cornish mines might well follow. The success at this mine is attracting considerable attention, and the results of reopening are in strong contrast to the misfortunes of its neighbor, Botallack. The other adjoining mine, the Levant, that has been worked continuously for a long time, is arriving at a crisis in its history. The landlords are demanding impossible terms for the renewal of the lease, and the shareholders, being mostly local residents, are utterly opposed to any modern idea connected with the technology or finance of mining. What the eventual upshot will be is more than I can say. It is remarkable how many people are now taking an interest in Cornwall. It appears as though many who have earned experience in Nigeria are desirous of not wasting it, and are therefore turning their attention to more hopeful lode-mining districts.

Tin is undoubtedly 'it' on the Stock Exchange at the present time. Bolivia is attracting attention as well as Cornwall, and, as a matter of fact, it is the only tin-producing country showing much promise. Bolivian ores are usually complex, silver, copper, tungsten, etc., being found in association with cassiterite. A company has been advertised this week, called the Porco Tin Mines, which has been formed with a capital of £125,000 for the purpose of developing the Porco mines in Bolivia. These have been worked in a small way for some years, especially for silver. The property is close to the branch line of the Antofagasta railway, connecting with Potosi, and is 25 miles from that city. The original owner is Arturo Arana, of Sucre, and the introducers are José Richards and James Edwards, the latter being secretary of the Great Boulder Proprietary company, owning the mine at Kalgoorlie. The firm of Avelina Aramayo & Co. are the commercial agents. They are the owners

of the Aramayo Francke mines at Chorloque, a hundred miles to the south toward Tupiza. Reports on the property have been made by José Richards, O. Gore Adams, the manager of the Llallagua tin mine near Oruro, and Bruce Marriott & Co. Richards' report is used as the basis of the prospectus. He estimates the ore reserve at the various workings at 45,000 tons, averaging 4.4% black tin. The cost of mining and concentrating is given as £32 per ton of metallic tin, and the cost of freight and smelters' charges in England as £28. There is a 10-stamp mill on the property, and it is first proposed to improve this and the accompanying dressing plant. A new mill of 20 stamps is to be erected with a capacity of 60 tons per day. The mine has been worked chiefly for silver in earlier days, and much tin ore has been left in the old stopes. The weak point of the prospectus is that the estimates of output and profit are based on the report made by Mr. Richards, who is admittedly interested in the sale of the property.

### BLACK HILLS, SOUTH DAKOTA

RELiance MILL STARTS.—WORK AT THE VICTORIA.

The New Reliance mill has started. During the shutdown the plant was given a thorough overhauling and the slime department improved by the addition of a Portland filter, which will be employed as the final stage in the decantation and agitation slime system used at this mill. The mill contains thirty 1000-lb. stamps, giving a capacity of around 125 tons per day. F. C. Bowman, of Trojan, is manager. The Heidelberg group, belonging to John Treber and A. T. Roos, of Deadwood, is being systematically developed with a small crew, and gives indications of developing into a good mine. At the present time the owners are driving along the edge of an ore-shoot, and will shortly cross-cut it to determine the width. The ore is of good grade; the only question remaining to be settled is the quantity available.

The Hailstorm property, in the Two Bit district, has been leased to Louis Arpino and associates, who have commenced work and hope to be making smelter shipments at an early date. On neighboring ground, the Monarch, Nicoli brothers are taking out \$80 to \$100 ore and shipping regularly to smelters. Mr. Arpino believes he will open up some similar ore in an extension of the Monarch shoot. Lessees on the Wells Fargo, in Blacktail gulch, are making regular shipments, most of the ore going to the Golden Reward cyanide plant and some to smelters. A crew of men is employed at the Golden Gate property, in Blacktail gulch, in repairing the head-frame and timbering the 100-ft. shaft, preparatory to installing a small electric hoist and starting development at the bottom, which is on the quartzite. Work is under the direction of C. C. Todhunter, who represents E. J. Hoover.

The Victoria mill is running steadily, and 100 to 125 tons of ore per day is being treated. The plant has been running a little more than a month now, and is getting down to a good working basis. Rolls are used for crushing, and the screens have been changed so that practically all of the product will pass 20-mesh. The ore is extremely hard and yields a good proportion of its content by leaching. Mill solutions are 4 and  $1\frac{1}{2}$  lb. cyanide per ton, respectively. Consumption is 0.4 lb. per ton. Two pounds of lime per ton of ore is added at the rolls.

Eastern people largely interested in bonds of the Branch Mint company are investigating the property, and there is a probability that operations may be resumed before long. A request was made that the County Commissioners cancel a certain amount of taxes, and this has been taken under advisement. A large amount of taxes is due on the property, but as it has not been a producer for several years, it is believed the Commissioners will make a liberal reduction. F. L. Clemens, manager for the Gilt Edge Consolidated company, is making a careful examination of its property, with the idea of arranging for a resumption of milling at an early date. The property is at Galena.

## JOHANNESBURG, TRANSVAAL

### THREE GREAT PRODUCERS OF THE RAND.—DETAILS OF OPERATION.

The struggle for supremacy between the principal Rand gold-mining companies has been attended with varying results. Providing labor continues plentiful it is still difficult to predict whether the Crown or Randfontein will ultimately lay claim to supremacy. At the present time the outlook is all in favor of the Crown Mines, for not only does its ore yield a higher return per ton, but, on the whole, the yield is more uniform, while both underground and on the surface operations have been so concentrated and facilities so increased that little variation ought to take place from one month to another.

During the past three years the Crown Mines has spent over a million and a half sterling in equipping and developing the property, with the result that it has been found necessary to issue a million sterling debentures, the remainder being partly supplied by available working capital and partly by working profits. The result of this expenditure has been to increase the ore reserve from a total of four million to over ten million tons, the estimated value of the gold content of which is over fifteen millions sterling. New crushing stations have been built and the capacity of the mills increased from 150,000 tons to 230,000 tons per month, as follows: Crown Deep mill, 90,000 tons; Crown Reef mill, 75,000 tons; and Langlaagte Deep, 55,000 tons per month. Not only has the capacity of the milling equipment been increased, but the whole of the surface and underground equipment has been overhauled and so concentrated that the working cost is expected to be lower than any similarly placed property on the Rand. With regard to the life of the property, it may be pointed out that the Crown Mines owns an extensive area, but is intersected by a huge dike. Operations have so far been confined to the northern portion, about a third in area of the property, the veins below the dike not yet having been touched. It is estimated, however, to contain at least a hundred million tons of ore. Considering that there is every reason to expect the veins to continue beyond the confines of the present property, it is premature and futile to attempt to estimate its ultimate life, but at all events there ought, at present scale of working, be ample ore to last about fifty years.

The position on the Randfontein property also seems to be improving, but the mammoth mill of 600 stamps erected on the property is only half employed, and it is difficult to foresee the period when the policy of erecting such a huge mill will be fully justified. At the present time the tonnage crushed is about equal to the maximum capacity of the combined Crown mills, but the yield per ton is lower, and although the working costs are lower, the average working profit per ton milled is only half that of the Crown Mines. Then again, the official figures of the Randfontein Mines, despite the lower content per ton and higher stamp duty, show that the ore reserve is only about half that of the Crown Mines. There are good reasons to doubt whether the whole of the alleged reserve of developed ore is as available for mining as that of the Crown Mines, despite the lavish manner in which the Randfontein property is supplied with milling equipment. The scattered mines of the Randfontein are also a drawback. The northern section developments are not by any means encouraging, and such a huge and scattered concern is sure to be handicapped in times of labor scarcity. Affairs are improving at Randfontein, however, and with its huge reserve of milling capacity the property ought always to press the Crown Mines closely in the race for premier position.

The only other probable competitor for the leading position on the Rand is the East Rand Proprietary, whose doings during the first half of the present year show that this property constitutes a factor that the other large amalgamations cannot always afford to despise. In the face of the unduly pessimistic report of the superintending engineer the results of mining operations during the past

six months are somewhat of a surprise, and clearly show that the despondent view taken by the new management was quite unnecessary, though as a policy perhaps justifiable. The tonnage treated fell considerably as compared with 1911, but the increase of the grade of ore milled from 25s. per ton to 32s. 9d. per ton, an improvement of nearly 2 dwt., gave rise to most surprise. But the costs advanced 5s. per ton, so that only 2s. 9d. per ton of the higher yield ranked as increased profit. The dip section of the East Rand Proprietary, represented by the whole present proved area of the Angelo Deep property east of the western shaft, as well as the Hereules property, is well known to be of very low grade. When worked, the ore will require considerable 'sweetening' from other areas. The question, therefore, naturally arises as to whether it is justifiable, with these future requirements staring the new management in the face, to sacrifice the richer portions by increasing the yield 7s. 9d. per ton, though only obtaining an increased

RANDFONTEIN MILL.

profit of 2s. 9d. per ton. The answer can only be supplied by those who control the future destinies of this huge property. During the last three months the grade of ore milled has shown a tendency to decline, and perhaps this may indicate that, as soon as possible, it is intended to abandon the forced selective mining policy of the past six months and proceed by crushing ore more in keeping with the average value of the ore reserves, looking for the maintenance of profits by lower working costs per ton and the treatment of an increased tonnage. It seems highly probable that the richer ore of these deep-level areas will be found beyond the water dike, where water troubles may naturally be expected, but with the installation of suitable pumps the water can be handled with ease. The development progress made during the past six months does not compare favorably with that for 1911, which the superintending engineer designated as utterly inadequate. When everything is taken into consideration it is clear that, despite the better results obtained during the past six months, the East Rand Proprietary is still a long way from being regarded as clear of all the difficulties and drawbacks which may sometimes give trouble.

Among the three principal Rand producers the Crown Mines promises to be the most consistent in the future, on account of its better and more uniform grade and the comparative ease with which not only the grade but also mining and ore reduction operations can be regulated, not to mention the huge reserves of ore. To bring the Crown Mines to this position has required a huge capital outlay, but there can be little doubt that in the long run this expenditure will be more than justified. It seems probable that the Crown Mines will usually be found at the head of the list of gold producers on the Rand and of the world. The Randfontein and East Rand Proprietary Mines will constitute good seconds and may occasionally be first; more especially Randfontein by virtue of its huge equipment, but there are so many difficulties to contend against underground in connection with both of these properties that they cannot be regarded as anything like as consistent producers as the Crown Mines.

## KALGOORLIE, WESTERN AUSTRALIA

### FRASER'S MINE FOR SALE.—NEW LABOR AGREEMENT.— BLACK RANGE IMPROVING.

Fraser's mine at Southern Cross, the first gold mine in this state to pay dividends, is for sale. The mine was floated in May 1889, four years before Bayley's Reward, at Coolgardie, was found; and paid its first dividend of \$6250 in 1890. By May 1900, when work was stopped, the mine had produced \$2,285,000 from 245,000 tons of ore, exclusive of residue, as the mine then had no cyanide plant. In 1901 the mine, with a 30-stamp mill and all accessories, was sold to the British and Foreign Development Syndicate for \$2500. This syndicate did no development. They leased to tributers, who took out another 81,000 tons from the old workings for a return of \$1,337,500, inclusive of gold from old and new residue. The whole of this gold was won from above the 300-ft. level, and taken from a pay-shoot 4000 ft. long. In January last the mill was shut down, and pumping was stopped; but tributers were allowed on the lease free of royalty, as the attorneys imagined that no ore could possibly have been left after tributers had been working the ground for 12 years. However, eight men began work, and their return during July was \$5575 from 324 tons, or \$17.20 per ton, a better average than had been previously obtained. Four years ago the Syndicate asked the Government to assist them to test the ground below 300 ft. by boring, and the Minister of Mines sent the government geologist, H. P. Woodward, to examine the mine. After an exhaustive inquiry, Mr. Woodward gave a favorable report. He pointed out that in addition to the lode worked, there were two other parallel lodes on the property, which had not been tested. The three would probably join in depth, when an enrichment might be anticipated. He closed his report as follows: "The only conclusion that can be drawn is that if boring is jointly undertaken by the Government and the company, it will be with every prospect of success." In spite of this nothing was done, and a mine which had produced \$3,625,000 from 352,600 tons, worked to a depth of 300 ft. only, is now a derelict, and, if not sold will probably be abandoned. No wonder Western Australia is in the doldrums.

There is a prospect of the Great Boulder Proprietary buying the Great Victoria mine, at Nevoria. Backed by a Government subsidy of \$5000, the owners, Delbidge & MacDonald, sunk a winze below the 300-ft. level, and continued the drift, which was then in 50 ft. After going another 50 ft., assays as high as \$60 per ton were obtained, and at 100 to 125 ft. the average assay value was \$13. A staff of samplers from the Great Boulder are thoroughly sampling the mine. Seven thousand five hundred tons of ore previously crushed showed the value for a width of 100 ft. to be \$7, but there appears to be an enrichment at the 300-ft. level, while the lode seems to be wider than ever. Richard Hamilton, manager for the Great Boulder, is a very cautious individual, far too cautious, in fact, for the good of the country; if all operators gave prospectors so little encouragement prospecting would automatically cease. The price asked for the mine is \$250,000, a mere bagatelle in most countries, but Western Australia has no capitalists.

The wages agreement at Kalgoorlie expires on September 30, and negotiations to extend the agreement for another period of three years are in progress. The five labor unions concerned have all held meetings to consider the ultimatum sent them by the Chamber of Mines. It is understood that the Chamber has offered to increase the pay of shovelers and trammers from \$2.64 to \$2.80, and to continue all other workers at the old rate. There will be a joint conference on September 1 to finally discuss the matter. Mining is at present so depressed that no general attempt to raise wages will, for a moment, be tolerated by the Chamber of Mines.

The Siberia Consols, at Waverley, was offered to Adelaide speculators for \$50,000 cash and a quarter interest in shares. The vein on this property is 45 to 120 ft. wide,

and has been proved by five shafts for a length of 600 ft. A total of 876½ tons treated from these shafts at the Government mill yielded \$1,040,000, or over \$118 per ton. This was picked ore, but the remaining 4000 tons on the dump is worth \$6 or \$7 per ton, so that the average of the whole lot is about \$25 per ton.

The Black Range, which has paid regular dividends of \$13,600 per month for years, is now opening out at a depth of 800 ft. This mine started with a cash working capital of \$58,750, and has already paid \$1,128,000 in dividends. The mine has produced \$2,927,300 from 148,000 tons since 1905, a wonderful record for a property picked up for \$25,000. This property was offered to most of the big firms of mining engineers, but they would not look at it, as the 35° dip was too flat to please them. Finally it was bought by Hans Irvine of Melbourne.

## RHODESIA

### LARGE JULY OUTPUT.—TATI CONCESSIONS.—RECORD OF THE LONELY MINE.

The gold output declared by the mines of Southern Rhodesia for the month of July is the third largest on record, and the production of other minerals is eminently satisfactory. The June and July productions are contrasted in the following table:

	June, 1912.	July, 1912.
Gold .....	£226,867	£240,514
Silver .....	1,826	2,017
Lead .....	928	916
Chrome iron .....	13,750	26,754
Coal .....	5,538	6,405
Totals .....	£248,909	£276,606

Apart from the substantial improvement shown in gold output, the large increase of chrome iron ore is especially worthy of remark. Clearly this is a branch of the mining industry in Rhodesia which is of growing importance. The properties of the Tati Concessions, Ltd., although not actually in Rhodesia, are always considered under the subject of Rhodesian mining. The Tati concession is really in the extreme northern portion of the Bechuanaland Protectorate and immediately adjoins southwestern Matabeleland. The quartz veins and the general working conditions are much the same as are found in the Matabeleland province. For years past the affairs of Tati Concessions have been in a languishing state, but recently the management endeavored to instill fresh life into the undertaking by introducing more generous mining regulations and in every way endeavoring to foster the prospector and tributer element in the territory. During the past few months prospectors have been arriving steadily, and good finds of gold, copper, and other minerals, are from time to time reported. The Durham Prospect Co. has possession of the New Zealand mine, and it is expected that crushing will be begun next month, after which monthly returns will be published. Arrangements are proceeding with responsible persons for the immediate development of the Monarch mine, and the Somerset, from which good results are stated to have been obtained. The Arab and the Giraffes claim have been let on tribute, and development is proceeding on the Charlie, Gloucester, Magdalen, Dollar Princess, Austria, Homeward Bound, and Piatra Reefs. A number of discovery claims have been registered, and apparently this hitherto much neglected district of small gold mines has attracted a number of prospectors and small capitalists from Rhodesia and the Transvaal.

The Lonely mine in the Bubi district was originally staked by two prospectors, who had considerable difficulty in raising £30 to register and protect their claims. Today the estimated profit is £518,000, there being 153,075 tons of ore developed, of an average assay-value of 23.26 dwt. per ton. This change has come about in a brief five years, and in the opinion of many the Lonely will continue to occupy an important place in the foreground of Rhodesian mining for a long while to come.

## General Mining News

### ALASKA

#### FAIRBANKS

On the right limit of 27 below Goldstream, three Russian miners have sunk 260 ft. and are still passing through gravel. This is one of the deepest workings in the country, nobody having any idea such a depth of gravel existed. It is all frozen. The deepest lode ever sunk in the placer workings of the district was on the Chatanika flats near the mouth of Sargent creek, where 310 ft. was sunk through frozen ground. During this work the prospectors used a shield to protect men in the shaft from falling pebbles. Rich ore has been found on the left limit of Goldstream, between Sheep and Nugget creeks, by O. Haines and Hudson brothers. Having worked out the ground opened for summer work on No. 17 Goldstream, the owners are sinking another shaft to be used in opening more gravel this winter. Peterson & Craig are sluicing night and day. No. 17 has already produced about \$1,000,000 in gold.

### ARIZONA

#### COCHISE COUNTY

Rich silver ore has been cut in the Ormos mine, 18 miles east of Cumpas, on the second level at a distance of 582 ft. from the mouth of the adit; but its extent has not been determined so far. From a vein 12 in. wide about 5 tons of ore has been broken. This mine has already produced \$70,000 from the upper workings. M. McWhorter and associates have taken up 30,000 acres of land for prospecting for oil, in the Lost Hills basin field, near Fairbank. On account of lack of funds, the Arizona Oil Co., which has a well down 1200 ft., has stopped

GREAT FALLS CONVERTER.

work; and the former people wish to pool their interests so that the well may be continued. The Minneapolis Copper Co. is resuming operations, and will continue the erection of its smelter, which was begun before Mexican rebels came on the property.

At the Copper Queen smelter, the first of the new Great Falls type of converters, which replaces two of the old barrel type, was blown in on October 18. Four more of these will be installed. In response to the wishes of a majority of its employees, the Copper Queen has decided to have pay-days twice a month.

#### GILA COUNTY

F. W. Hoar, manager for the Southwestern Miami Development Co., has taken an option on the Prospectors' group of 13 claims for \$125,000. The prevailing formation is Pinal schist, much of it being mineralized, and it will be prospected by churn-drills. Shipments are being maintained from the Black Warrior mine to the Old Dominion smelter. The ore averages 7% copper. Surface equipment, and retimbering and enlarging the Copper Hill shaft at the Arizona Commercial is finished. The cross-cut on No. 16 level of the Old Dominion has passed

through 8 ft. of chalcopryite and bornite ore, averaging 12% copper.

#### GREENLEE COUNTY

(Special Correspondence.)—N. L. Amster recently visited the Shannon at Metcalf, where they are opening ore 100 ft. lower than it has been mined before, and are taking out ore averaging 4 to 5% copper. The extension of the orebody has been proved to a point below the level of the Carter adit, which is a very important development. Production for September was below normal because of the freezing of one of the furnaces, and this months' output will also be smaller than usual, but is now increasing, and next month will show a decided increase. A considerable amount of development has been done during the past six or eight months, and from \$7000 to \$8000 per month is being spent for that purpose, all of which is included in the operating costs.

Clifton, October 17.

#### MOHAVE COUNTY

The Needles Mining & Smelting Co. is sinking the shaft of the Tennessee mine, at Chloride, to 800-ft. depth. On the 700-ft. level a good deal of ore has been opened. R. H. Cameron has taken a bond on the Loper and Carney mines, 8 miles east of Hackberry, in the Cottonwood mining district. The ore developed will average \$20 per ton. The owners want \$50,000 cash for the mines, which are near a railroad. Development is to be started at the Swope and Studley properties, in IXL basin. In cutting out a road on one of the claims, a vein of lead ore was opened. W. D. Grannis and F. B. Holcomb have been examining the mines of the Arizona Venture Corporation.

#### PINAL COUNTY

(Special Correspondence.)—It is stated unofficially that the American Smelting & Refining Co. has released its option on the Lake Superior & Arizona mine at Superior, after unwatering the mine and making an examination. The Calumet & Arizona company has a few men on the Newman-Thompson-Daggs group of 81 claims recently acquired under option at Superior, and is making arrangements to secure electric power from the Ray Consolidated mine, 14 miles distant.

Florence, October 17.

#### SANTA CRUZ COUNTY

(Special Correspondence.)—The former president of the old Arizona Commercial Copper Co., N. L. Amster, when speaking of the R. R. R. mine near Patagonia, said: "We have just cut a new orebody, parallel to the one on which we have been working, and 100 ft. from it, which is 23 ft. wide and averages 8 to 10% copper, and we are now driving on it. On the first orebody two stopes from 70 to 80 ft. long have been opened for a width of 40 ft., in ore which will average 10% copper. The winze is down 110 ft., and has 9% copper ore in the bottom. We are putting in a set of scales, and by October 20 will be shipping 100 tons of ore per day averaging from 8 to 10% copper, and this may later be increased to 150 tons per day. We are employing about 70 men." Engineers and others who have examined the mine say that it is the largest and richest body of copper ore ever opened in Arizona with such a small amount of work.

Nogales, October 17.

### CALIFORNIA

#### BUTTE COUNTY

The Oroville Dredging Co. handled 95,349 cu. yd. of gravel, yielding gold worth \$11,069, during the week ended August 31, and for the financial year to August 31, a total of 430,108 cu. yd. was dredged yielding \$49,188.

#### MODOC COUNTY

(Special Correspondence.)—The sheriff of Modoc county has given official notice of the sale of the Ft. Bidwell Consolidated mines to satisfy a judgment for \$12,164 in favor of James Williams. The date of sale is October 28. It is reported that representatives of the company plan

to buy it in. Failing to do this, the company has six months in which to redeem the mines. Considerable southern California capital is interested in the mine, while much stock is held by Detroit people. A number of companies are arranging to conduct operations in the Gold Basin portion of the High Grade field. This lies in the lower region, where the light snowfall does not seriously impede work.

Ft. Bidwell, October 18.

#### NEVADA COUNTY

(Special Correspondence.)—The Gold Point mine, at Union Hill, near Grass Valley, is being worked in a small way by A. Onn, a Colorado miner, who lately came here. The mine is between the well known Idaho and Brunswick mines, and the operator states that he has found an extension of the recently discovered Brunswick vein. The shaft on the Gold Point has been deepened 50 ft. and development is yielding ore of high value. The new hoist, which is capable of hoisting from 1200-ft. depth, is ready for work. The main shaft has been timbered to 230 ft., and it is intended to sink 300 ft. farther. Some good ore has been taken out of the mine, and Grass Valley men are quite sanguine about future prospects.

Grass Valley, October 21.

The Grizzly Ridge Mining Co., which is operating the Oustomah mine on Wet hill, has made a contract with the Pacific Gas & Electric Co. to supply electric power, which will displace the present water-power, although this will be always available in case of emergency. E. C. Klinker is in charge of the property. The mine has been unwatered to the 500-ft. level, where a vein was exposed by collapse of the workings, and work is to be started on this vein on the 300 and 500-ft. levels. As soon as it has been opened enough, the 10-stamp mill will commence work. After the mine-water is out from the 1050-ft. level, sinking will proceed to 1500-ft. depth. The Oustomah was formerly known as the Pennsylvania and is one of the oldest quartz properties in the district. Preparations are being made for working the Flat Iron placer mine, above Camptonville, as soon as there is sufficient water for sluicing.

#### PLUMAS COUNTY

The California-Utah Gold & Copper Co. has seven claims, about 12 miles from Doyle, in this county, and during the past few weeks a hoist of 1000-ft. capacity has been purchased, bunk-houses built, and the property put in order for work on an extensive scale. When the Utah people took over the property, a shaft had been sunk 60 ft. in ore, and a cross-cut passed through 16 ft. of ore. On the surface a large lode can be traced for 2000 ft. It consists of a leached iron gossan, copper showing a few feet below the surface. The property is situated at an elevation of over 6000 ft., while there is plenty of timber and water available.

#### SIERRA COUNTY

The owners of the Mountain House group of gravel claims have bonded them to San Francisco people. They consist of seven locations of 160 acres each, and there is plenty of timber for mining purposes. The work for the year will be done in an adit from McKenzie diggings.

#### SISKIYOU COUNTY

For a considerable time past a large power-plant and dredging project has been spoken of, to be erected at the junction of the Klamath and Salmon rivers, 20 miles below Forks of Salmon. At this point is a mountain, and a tunnel will be bored from the Klamath river across to the Salmon, just above the base of the mountain. The power station is to be built at the Salmon end of the adit where a 50-ft. head will have been gained in passing through the two-mile tunnel. In the dry season the former river would be drained into the latter, and the electric power generated will be used on a dredge to be built to work that part of the Klamath river drained between

the head of the tunnel and the junction. The company wants a 50-year franchise, and is prepared to spend \$1,000,000 on the work. Besides dredging, it is intended to start other works, supplied by power from the plant.

#### TRINITY COUNTY

The Globe Consolidated Mining Co. has completed its tunnel through Globe mountain. It is 1723 ft. long and 600 ft. below the summit, and was found necessary for the cheaper working of the Chloride, Bailey, and Globe mines. Below the tunnel on the west side, the Globe mill will be built. About 300 tons of machinery has been delivered at the property, including a 20-stamp mill and cyanide plant of 100 tons capacity. Over 100 men are employed.

#### TUOLUMNE COUNTY

Work has been started at the Wickham mine by the Mother Lode Syndicate, which has taken it under option. The Mangate mine is being unwatered preparatory to further development. The Santa Isabella group of claims is being examined by Los Angeles people.

### COLORADO

#### CLEAR CREEK COUNTY

(Special Correspondence.)—An 8-in. streak of silver-lead ore has been uncovered on the Rosebud property on Democrat mountain which yields 180 oz. silver and 34% lead. Stopping has been started. G. W. Teagarden is manager. T. W. Cunningham, leasing on the Gambetta mine, on Republican mountain, has found a 4-ft. body of zinc ore which assays 51% zinc and 36 oz. silver per ton. From three to four carloads are being shipped each month. Hurley & Co., leasing on the Harris mine, in East Argentine, made a shipment of five tons of second-class ore this week which returned 450 oz. silver per ton. These lessees are driving on a 14-in. vein. There is also showing a 2-in. vein of glance which carries 15,000 oz. silver per ton. Work has been resumed on the Gold Coin mine on Griffith mountain. L. Hoery, the owner, will start shipments of lead-zinc ore during the coming month, the product to be sent to the Mineral Chief mill for concentration. A rich shoot has been cut on an unknown lode, and from a shipment of two wagon-loads returns of 190 oz. silver per ton were realized. This lode was penetrated 800 ft. from the portal of the Silver Plume adit on McClellan mountain, and the shoot is showing for 300 ft. H. L. Roberts, of Idaho Springs, is manager. Work has been resumed on the Dewey property in East Argentine district. Oscar Johnson is owner. The Mineral Chief mill is finishing on an average two tons each of lead and zinc concentrate per day. A. L. Stephens states that he is treating about 100 tons of ore each week from the New Boston mine on Democrat mountain. The shipments from the Santiago mine in East Argentine average two carloads per week, the product being consigned to the Salida smelter. The average value of the ore is \$90 per ton. D. H. Burlingame is manager. Shipments of high-grade ore have been started from the Kittie Ousley mine, in West Argentine. Operations are being carried on through the 200-ft. shaft, and stopping is in progress on a 10-in. vein.

Georgetown, October 16.

#### LAKE COUNTY (LEADVILLE)

It is generally known throughout the country the great benefit the Yak tunnel has been to this district, but few people know the area of ground which it has made possible to be profitably worked. Properties which had been idle for years on account of the heavy expense of coping with water, are today being worked on a large scale. Through this adit, mines on Carbonate, Iron, and Breece hills, and in Big Evans gulch, are being developed. There are 34 sets of lessees working along the adit on 21 claims, and several of these claims have as many as four sets of lessees working different blocks of ground. The average monthly shipments total 12,000 tons.

About 25 tons of ore is being sent daily to the smelter from the Sugar Loaf Consolidated, which shows improve-

ment of late. The Eagle Mining & Milling Co. is to enlarge its mill, and new roasting furnaces, tables, and magnetic separator will be installed, making the daily capacity 120 tons. The ore contains lead and zinc. Lessees at the Highland Chief, Breece hill, have opened 3 ft. of carbonate of zinc ore.

#### GILPIN COUNTY

The main shaft at the Ralls County mine is down 795 ft., and will be continued to 1000-ft. depth. The vein in the shaft at present is 8 ft. wide, showing copper ore. On the 500-ft. level the east drift shows  $3\frac{1}{2}$  ft. of ore worth 2.2 oz. of gold and 3.8 oz. of silver per ton. A good deal of development is being done at the Belden mines, on the Spencer, Ranney, and Black Quartz lodes. Seventy tons of ore has been sent to the mill by the Castle Rock in Chase gulch. The usual work is under way at the Wood, Gomer, and West Calhoun mines, while the East Centennial, Pratt, Ethen Allen, Elephant, and Togo lodes are being worked by local pools. The Golden Flint company has completed its aerial tramway from the mine to the mill, a distance of about one mile.

#### SAN MIGUEL COUNTY

During September the Tomboy mill worked 28 days and treated 10,000 tons of ore yielding bullion and concentrate worth \$84,000. The net profit was \$40,000, and \$11,300 was spent on improvements.

#### TELLER COUNTY (CRIPPLE CREEK)

The sampler at the Colburn mill is finished, and the mill resumed treatment of ore on October 16. It has

COLBURN MILL, CRIPPLE CREEK.

now a capacity of 3000 tons per month in treating ores by the Clancy process. It is stated that the process used is cheap enough, but the mechanical arrangements have made high costs. Eastern people interested in the Midget-Bonanza property have made an inspection, and in all probability a mill will be erected. Ore is being mined on No. 8, 9, and 10 levels. The Trilby mine, on Bull hill, is shipping about 25 cars of ore monthly from the 1100-ft. level, while the Isabella has sent out 35 cars for the first two weeks of October. Work on the 1275-ft. level proceeds steadily. During the week ended October 14, the following shares were dealt in at Colorado Springs: El Paso, 300; Elkton, 5150; Isabella, 21,000; Mary McKinney, 5000; Portland, 600; and Vindicator, 2000. The employment bureau for the district has proved to be a great success.

#### IDAHO

##### SHOSHONE COUNTY

More timber will be cut in the Pine Creek district this year than before, and it is estimated that 5,000,000 ft. will go down the Coeur d'Alene river next spring. The Springston Lumber Co. has bought all the white pine lumber. The district is rapidly attracting the attention of miners, who will work through the winter. The Highland Surprise, Nabob, and Amy-Matchless will employ a good number of men.

The directors of the Caledonia Mining Co. are to defend

title to their orebodies against the Bunker Hill & Sullivan company. Several experienced mining engineers have been engaged, and a thorough examination of the disputed ground will be made. Under the restraining order issued by the court, the former company can continue to mine ore as long as it is stored on the property. It will be prepared for shipment, as the court allows a nominal fee for mining while the case is pending, although the Bunker Hill establishes its claim to that part of the property.

Work has been resumed in the Bunker Hill portion of the Bunker Hill & Sullivan, and the first ore was shipped since the fire. The men are working on No. 10 and 11 levels and will soon be on No. 12. Pumps have been installed and No. 13 is being unwatered. Repairs at the shaft and hoist are nearly finished.

On October 16 the Stewart company was denied an injunction against the Ontario company. This decision is not final, and is subject to appeal. In the meantime the latter company can mine ore and is not compelled to account for the proceeds of its shipments. This is a case where the Stewart company claims the veins in the Ontario property by the law of the apex.

#### NEVADA

##### ESMERALDA COUNTY

At the Grizzly Bear claim of the Goldfield Consolidated a cross-cut is being extended south toward the Atlanta, at a depth of about 1350 ft. At 1330-ft. depth in the Merger a cross-cut is being driven at the rate of 15 ft. per day toward the western boundary of the St. Ives claim. It has been found that the dump at the Kabawgam claim, owned by the Begole Syndicate, is not waste as was supposed, but ore worth \$22.79 per ton in gold, silver, and copper. This came from a depth of 370 ft. west of the Consolidated. Shipments have been resumed from the Florence Goldfield. Two leases have been recently granted at the Combination Fraction. The Blue Bull shaft is down 525 ft. and is in promising formation. A shipment of high-grade ore has been made from the company workings of the Black Butte.

##### HUMBOLDT COUNTY

An 18-in. vein has been cut on No. 10 level of the Seven Troughs Coalition mine, and assays over \$100 per ton. A basalt dike has been entered on the sixth level, with veins of quartz showing. The cross-cut should enter the Jess-Bard vein within 100 ft. Lessees have part of the old workings of the property above No. 2 level. Old workings of the Industry group are being cleaned out preparatory to prospecting for rich silver and gold found there.

##### NYE COUNTY

During the week ended October 19 the mines at Tonopah produced 10,848 tons of ore valued at \$271,200. The September tonnage was 43,530 from all mines. The Tonopah Mining Co. treated 14,806 tons, yielding 253,700 oz. of bullion worth \$212,100, and shipped 56 tons of concentrate worth \$32,800. The net profit for the month was \$154,073. The Tonopah Belmont treated 12,405 tons, yielding 356,241 oz. of bullion worth \$290,401, with a net profit of \$170,496. On October 18 this company shipped 132,514 oz. of bullion valued at \$109,000, the result of the first 10 days' work of the current month. Preparations for sinking the main shaft are still in progress, the concrete bulkhead in the sump is being set, and the pump station nearly finished. There is little fresh to report from the Tonopah Mining Co.'s property. A shipment of 48 tons of ore from the North Star last week returned about \$106 per ton, and another car of similar ore has been sent out. This ore comes from the 850 and 1250-ft. levels. At the Merger, on the 980-ft. level, the west drift was extended 30 ft. in the ore-shoot, assays returning from \$80 to \$100 per ton. A good deal of improvement has been shown in the Jim Butler, and good ore is being mined on the 600-ft. level. The MacNamara company shipped last week bullion worth \$12,000. Owing

to the breaking of the chain-drive belt on the 150-hp. motor driving the tube-mills, the West End mill was shut down for 22 hours. The diamond-drill at the East End is down 382 ft. in andesite rock. The Buckeye-Belmont shaft was down 1035 ft. on October 15, with a flow of water about 1300 gal. per day. The shaft is of two compartments, each 4 by 4 ft. in the clear. Costs of sinking per foot are as follows: April, \$23.35; May, \$23.49; June, \$24.82; July, \$31.39; August, \$30.80; and September, \$30.46 per foot.

Production of the White Caps mine, at Manhattan, from May 24, 1911, to October 1, 1912, has been published by the secretary of the company. There were 5718 tons treated valued at \$169,948, of which 144,437 was recovered. The company received \$15,506 in royalties, while the lessees got \$85,596 net. A new orebody has been discovered in the old Bath lease, now worked by the Litigation Hill company. It is 6 ft. wide and averages over \$20 per ton. On the Kendall-Douglas lease, at the Manhattan Consolidated, a rich vein 16 in. wide has been opened, parallel to the main lode of the property.

#### STOREY COUNTY

Since the last assessment, No. 89, levied June 30, 1910, the Ophir company has produced 23,500 tons of ore yielding \$821,880, and a net return of \$724,941. Three dividends of 10c. each, equal to \$60,480, have been paid. The Ophir has paid \$202,706 to the Comstock Pumping Association. The new cyanide plant, which cost \$36,000, is now treating the tailing near the Kinthead mill, in Virginia City, of a gross value of \$120,000, of which \$90,000 can be recovered. Since September 1903 the Ophir has paid 12 dividends totaling \$282,240, and collected two assessments of \$100,800.

The recent development on the 2500-ft. level of the Sierra Nevada has been the cause of much speculation, and many visitors have inspected the mine. On the hanging wall is a rich vein 8 in. wide, which assays from \$175 to \$504 per ton, while the remaining 24 in. of ore averages \$20 per ton. During the week ended October 19 the Mexican mill treated 451 tons averaging \$50.35, with 94% extraction. The north stope on the 2500-ft. level yielded 530 tons worth \$71 and 83 tons worth \$22.22 per ton came from the 2400-ft. level. The total mine production was 624 tons, worth \$41,000. At the C. & C. shaft all pumps worked full time, and necessary shaft repairs were made. At the Ward shaft, pumps and other equipment are being removed from the 2100 and 2475-ft. stations. The Crown Point shipped 661 tons of ore to the Yellow Jacket mill.

#### WHITE PINE COUNTY

(Special Correspondence.)—The Nevada Consolidated company started work at Copper Flat last week with 85 men, and gradually increased the number to 200 men. There will be no recognition of the Western Federation of Miners. When the strike was called the ordinary miner had no voice in the matter. Rule or ruin has been characteristic of the union methods from Coeur d'Alene to Cripple Creek, and they will not succeed at Ely or at Bingham. At the Boston-Ely, diamond-drilling was tried in the formation below the 1245-ft. level, that is, below water-level; but the ground caved. The manager is driving southwest from the Emma shaft to cut the old Matilda vein, which had a good gold and silver content at the surface. One vein 30 ft. wide, containing chalcopryite, and assaying 7% copper and over \$5 in gold has been opened. There is a large area of leached ground between the surface and bottom level.

Kimberly, October 15.

#### SOUTH DAKOTA

##### LAWRENCE COUNTY

The Homestake declared its regular monthly dividend of 50c. per share on October 17. The amount payable on October 25 is \$109,000, and the total paid to date is \$23,443,550.

#### UTAH

##### BEAVER COUNTY

The Horn Silver claims are being surveyed, and considerable new work is planned. Ore assaying 61.7% lead, 20 oz. of silver, and a trace of gold has been cut on the 210-ft. level of the Noonday property.

##### EMERY COUNTY

A. L. Canfield, of New York, is stated to have secured an option for purchase of the Oscar Beebe vanadium property for \$20,000.

##### JUAB COUNTY

The lease of the Galena King mine is proving satisfactory, and ore carrying lead, silver, and gold is being shipped, the last carload returning \$1877. Zinc ore is being opened to some extent at the Yankee Consolidated mine, and six carloads per month are being shipped, the last lot of 95 tons yielding a net return of \$2219. An explosion of powder in a temporary storage house at the Chief Consolidated resulted in damages costing \$500. Owing to the Tooele smelter shutting down its copper furnaces on account of the Bingham strike, the Chief will send a limited supply of ore to the United States S. R. & M. Co.'s plant. The electric pumps at the 2200-ft. level of the Centennial Eureka are being removed, and this part of the mine will fill with water. A site for the new mill for the Knight mines has been selected on the Boston & Tintic property. The process will include roasting and chlorination. About 180 ft. above the 500-ft. level of the Iron Blossom mine an orebody over 10 ft. wide and assaying from 40 to 70 oz. silver and 25 to 30% lead has been opened. The Opohongo has paid a dividend of 2c. per share, amounting to \$20,000. Ore shipments from the Tintic district during the past week totaled 170 cars, of which the Centennial sent out 40 and the Chief 23 cars.

##### SALT LAKE COUNTY

There has been little trouble at Bingham during the past week, and about 1000 men are at work at the mines. Strike-breakers are arriving, and the strikers have made sundry demonstrations. Four steam-shovels are at work; and 5000 tons of ore has been sent to the Arthur and Magma mills. None of the millmen joined the strikers. The smelter at Garfield is still working. Various statements have been made by both sides, but the management apparently has the best of the argument.

The Intermountain Transportation Co., with a capital of \$300,000, has been formed in Salt Lake City to maintain a modern haulage system throughout Idaho, Utah, and Nevada. The company is to use motor trucks in the various mining districts for carrying freight, and will have four at work within 60 days. A large tonnage has already been contracted for. It is argued that many mining districts would now be active if there were cheap methods of transport. Directors of the Michigan-Utah company visited the mine last week. All the ore mined is to come from the City Rocks side of the range, and a hoist is being installed at the winze connecting the old City Rocks and Solitude adits. The latter was driven into the mountain by the old Utah Mines Coalition Company.

##### UTAH COUNTY

A draft for the sum of \$1,800,000 has been drawn by Jesse Knight, as president of the Knight Power Co., on the Electric Bond & Share Co. of New York, who bought the power-plants. The proceeds will be used in settling the affairs of the power company. A committee will attend to the dissolution and handing over the properties to the new Utah Power Co. The final dividend to the shareholders will be \$140 per share.

#### WASHINGTON

##### FERRY COUNTY

The Imperator-Quilp company, of Spokane, which has been working the Quilp mine in the Republic district, under option to purchase, has commenced suit against the Quilp company and its secretary for \$410,000 damages, on the

ground that fraudulent maps of the property were supplied. The option price was \$250,000, of which \$15,000 was to be paid on or before September 24, 1910, and \$5000 every 90 days thereafter until the purchase price was paid, provided this was done by March 9, 1913. At the time of the contract, the Quilp mine had estimated ore reserves of \$200,000, which were marked on plans supplied to the purchasers; also, that part of the mine which the plans showed to contain ore was under water, and the purchasers had to rely on representations of the Quilp people; and also it was found that the orebody was in another claim adjoining this mine.

#### STEVENS COUNTY

In an adit 700 ft. long and at a depth of 325 ft., the Aurora Mining Co. has opened 25 ft. of high-grade copper ore, and as soon as bins are built shipments will be made. Near the portal of the adit a large vein was opened last spring. Shipments of gray copper ore are to be sent from the Superior mine, near Brown's lake, in the Chewelah district.

### CANADA

#### BRITISH COLUMBIA

During the first nine months of the current year, mines in the Slocan district have shipped 4725 tons of zinc and concentrate, to which the Lucky Jim contributed 1106 tons of ore averaging 50% zinc; Van Roi, 1981; Standard, 1504; Hewitt, 100; and Noble Five, 34 tons. The Rambler-Cariboo is expected to join the list of shippers shortly.

#### COBALT

Since 1904, the production of this district has been 140,230,383 oz. of silver, worth \$72,263,952, while \$35,242,318 has been paid in dividends. The Beaver Consolidated mill is to be increased to treat 120 tons per day, due to the favorable nature of development at the 530 and 600-ft. levels. During the past week the Nipissing company sent 154,273 oz. of silver, valued at \$99,521, to London, England. Timiskaming dividend amounts to \$75,000. The company has cash in bank totaling \$255,650, while there is \$65,803 owed by the smelters, and ore worth \$34,261 is on hand. The Coniagas dividend of 12% is payable on November 1, making the total to date 107%, equal to \$4,280,000.

#### DAWSON

In September the Yukon Gold Co.'s dredges handled 944,300 cu. yd. of gravel averaging 54c. per yard, with a total yield of \$515,000, against 727,948 cu. yd., 69c. per yard, and \$506,577 in September 1911. For the season to September 30, gold recovered has totaled \$2,917,700, against \$2,172,582 for the previous season.

#### PORCUPINE

The Hollinger company has declared a dividend of 3%, payable November 2. In future dividends are to be paid every four weeks, this being equivalent to 39% per year. The Dome Lake company, which holds three claims in this camp, is to be reorganized, and the capital reduced from \$2,500,000 to \$500,000. Mine development has been satisfactory of late, and the stamp-mill will be ready in a few weeks. The main shaft of the McEneaney is down 400 ft. On the 200-ft. level about 600 ft. of work has been done on the lode, with 7 ft. exposed at the face of the drift. All concrete foundations at the Dome Lake mill are finished. In the mine three levels are being driven on No. 3 vein, where the average width is about 3 ft. of high-grade ore. At the Dome Extension most of the development is being done on the 200-ft. level.

### MEXICO

#### CHIHUAHUA

(Special Correspondence.)—On the morning of October 2 a band of rebels numbering 150, under de la Torre,

unexpectedly visited the Concheno property and demanded \$10,000 and a supply of food and clothes. As October 1 was pay-day there was only \$500 on hand. The rebels then helped themselves to \$10,000 worth of goods at the company's store, giving receipts for money and articles commandeered. They also took several horses and gear, and searched the houses of Americans and Mexicans for money, arms, and jewelry. No violence was attempted, and no resistance made, but two Americans were fined \$200 each for having weapons hidden. The rebels were disappointed and threatened to kidnap two Americans to hold for ransom. They were armed with Mausers, but had little ammunition, and appeared nervous. Detachments of Federals from Dolores, Ocampo, and Guerrero were trying to surround them. The migration of rebel bands to the south is what the mines have to fear.

Concheno, October 5.

After a shut-down for two months caused by rebels infesting the district, the Yoquivo Development Co. has resumed work at its mine and mill. The district is free from trouble now, and the manager, C. Qualey, hopes to continue operations. Rebels have also disappeared from the Ocampo district, and the La Princesa, in Cusiuhirachie, has been shipping ore to the Chihuahua smelter for some time. The Rio Plata Mining Co., of the Arteaga district, is operating its mine and mill full time. No uneasiness for the future of the Parral district is felt by mining and business men, and lately several mines resumed operation. The railroad is busy carrying ore to the smelters at Chihuahua, Mapimi, and Torreon. Business generally is gradually improving, and a fair number of prospectors have gone into the hills. Despite the rebellion of the past four months, the Cusi Mining Co. has maintained ore shipments to the

MAP OF MEXICO.

smelters. More machinery is to be installed, and a new mill may be erected early next year. C. R. Watson is manager. Owing to the stoppage of railroad communication, shipments of copper from the Rio Tinto could not be made, but now that conditions have improved, it is being sent daily to El Paso. During the shut-down all machinery was overhauled.

### PERU

The Inambari Gold Dredging Concessions, Ltd., of London, has raised the necessary capital to continue its work with the large dredge completed this year. The Huinac Consolidated Copper Co., Ltd., was formed in London in July, with a capital of \$2,000,000, and absorbed the mines of the Huinac Copper Mines, Ltd., in liquidation. The mines are in the province of Huarez. T. H. Foulkes, with 10 miners and mechanics, has sailed for Salaverry, on the way to the mines of the Compania Minera Ophir, Ltd., at Salpo. They will lay the new track and install an air-compressor in the working adit, from which it is proposed to begin development of this important group of mines.

## Personal

Professional men are invited to send news of their engagements and travels. Such news is interesting to friends.

W. F. WOOD is in San Francisco.  
H. FOSTER BAIN is at Cleveland.  
JAMES A. POLLOCK is at Alta, Utah.  
MURRAY C. GODDE is in the Northwest.  
J. P. KEENE has gone to Mono county.  
JOHN B. FARISH is at the St. Francis.  
C. H. BAILEY was here during the week.  
M. S. MILWARD is here from Chihuahua.  
CHARLES E. VIRDEN is at the St. Francis.  
R. H. CHAPMAN has returned to Montana.  
CHARLES G. PATRICK is here from Goldfield.  
R. L. HUSSEY, of Los Angeles, is at the Palace.  
W. H. LATTIMER was in San Francisco recently.  
EDMUND JUESSEN has gone to Kingman, Arizona.  
WILLIAM BURNETT, of Cobalt, is in San Francisco.  
CLARENCE BAMBERGER was at Ely, Nevada, recently.  
GEORGE H. HAYES was here from Los Angeles last week.  
C. G. ROTHSCHILD is now at 43 Leonard street, New York.  
J. M. CALLOW has returned from the East to Salt Lake City.

E. J. COLLINS was in Tonopah last week on professional business.

JOHN H. MILES was in San Francisco and has returned to Idaho.

E. F. BURCHARD was in San Francisco and has returned to Washington.

PERCY E. BARBOUR has returned to North Carolina from New York City.

KINGDON GOULD has been inspecting his coal properties in southern Illinois.

BARRY SEARLE has gone to Nicaragua to spend a month at the Lone Star mine.

A. D. LEMAIRE, of Valley Mountain, Nevada, has been visiting San Francisco.

WALTER F. STEVENS, manager for the Ferrobamba mines, has returned to Arquipa.

NOEL CUNNINGHAM is now mill superintendent for the Hollinger Gold Mines, Limited.

MARSHALL S. WALKER is now at the United States Assay Office, 23 Pine street, New York.

J. A. HOLMES was in town during the week and expects to sail for Panama on November 2.

HENRY B. KAEDING is making an extended trip to the copper mines of the Lake Superior region.

RICHARD B. STANFORD has left New Orleans for a few weeks trip to the Topaz mine in Nicaragua.

F. J. COLEMAN, assistant mine superintendent for the Detroit Copper Co. for many years, has resigned.

E. C. VIGEON, assistant general manager for the Spassky Copper Co., left London for Russia on October 4.

C. W. PURINGTON passed through San Francisco on his return from Alaska and is now at Brookline, Massachusetts.

R. B. LAMB is making a professional trip to the Gowganda silver district and will go to the goldfields of northern Ontario.

## Obituary

CHARLES R. H. BLYTH died of typhoid fever at Aranzaru, Zacatecas, Mexico, on September 19. Mr. Blyth, who was a graduate of Freiberg, was an engineer of prominence, and his death at the age of 28 is generally regretted.

THOMAS PRICE died at his home in San Francisco, October 13, at the age of 77, from heart failure. He was born in Wales and became professor of chemistry in the Normal College at Swansea, but came to San Francisco in 1862, where he assisted in the organization of the Cooper Medical College. The later years of his life were spent in consulting work, in which he attained enviable distinction.

## Market Reports

### LOCAL METAL PRICES

San Francisco October 24.

Antimony .....	11-11½c	Quicksilver (flask) .....	41.50
Electrolytic Copper .....	18-18½c	Tin .....	52-53½c
Pig Lead .....	5.35-6.30c	Spelter .....	8½-8½c
Zinc dust, 1400 lb. casks, per 100 lb., small lots \$9.50-9.75; large \$7.50-8.50			

### METAL PRICES

(By wire from New York.)

NEW YORK, October 24.—Copper is easier because of European sales. Lead is easier on account of Western sales. Spelter is steady, but the business done is small. Average daily prices for the past week, in cents per pound, based on wholesale transactions, standard brands, are given below.

Date.	Electrolytic Copper.	Lead.	Spelter.	Silver, per oz.
Oct. 17 .....	17.35	5.08	7.28	63½
" 18 .....	17.35	5.08	7.28	63½
" 19 .....	17.30	5.08	7.28	63½
" 20 .....	Sunday.		No market.

## James Lewis & Son's Copper Report

Standard copper fell from £79 7s. 6d. for cash on September 2 to £78 2s. 6d. on the 13th, gradually recovering to £79 1s. 3d. on the 23rd, with sales since between £78 16s. 3d. and £79, until September 30, when £79 5s. was paid. Closing prices are £78 17s. 6d. for cash, and £79 15s. for three months prompt. Sales totaled nearly 35,000 tons.

A large business, estimated to be about 25,000 tons, has recently been transacted in electrolytic copper for English consumption, and also for export to Europe at 17<sup>3</sup>/<sub>4</sub>c. per pound for the former and £81 15s. per ton for the latter, by American refiners, who have now raised their selling price to £82 per ton, at which some business has been done. Against their purchases of refined copper, European dealers have freely sold standard, with three months prompt, at £79 10s. to £80 per ton.

The future price depends upon whether the present large consumption in Europe and the United States will be fully provided for by the greatly increased and increasing production of American and other mines, stimulated by the large profit consequent on the advance of 40% in the value of copper, as compared with the average price of last year.

The enlarged equipment of the Hampden Cloncurry mines, in Queensland, will enable an output of 650 tons of copper per month, while the Mt. Elliott mine, also in this state of Australia, produces about 700 tons per month.

American shipments from northern ports for the past month are advised as 25,572 tons. European stocks decreased 1262 tons, and the visible supply 2387 tons during the month. Imports are 2569, and deliveries 7576 tons less than the same period last year. Total arrivals in England and France for the month were 14,394, and deliveries 14,697 tons fine. Arrivals in England from Chile were 1949, and deliveries 2228 tons; and from other countries 9653 and 9375 tons, respectively. Liverpool and Swansea received from the United States 2050 tons of bars and 695 tons of plates, equal to about 2734 tons fine copper; in London 759 and in France 2332 tons. Chile charters for the month are advised as 2700 tons, including 1225 tons for the United States.

## Company Reports

### SOUTH AMERICAN COPPER SYNDICATE

This company was formed in 1907 to reopen the Oroa group of copper mines in Venezuela, ancient mines that between 1887 and 1894 were worked by the Quebrada company, an English concern. The capital of the company is £15,000, of which £9983 has been paid up. During the year ended June 30, 1911, the ore mined and shipped to Europe realized £75,447 at an operating expense of £47,803, yielding a profit of £27,644. Dividends totaling £32,358 have been paid, corresponding to 250% on the paid-up capital. W. A. Heywood has been sent to study the metallurgical problems involved.

### DE LAMAR COMPANY, LTD.

This company was originally formed in 1891 to acquire from Henry Bratnaber 415 acres of mining property in Owyhee county, Idaho, which had been worked for gold and silver by J. R. De Lamar. The original company, the De Lamar Mining Co., Ltd., made good profits for a time and paid dividends totaling 107<sup>1</sup>/<sub>2</sub>% of the original capital of £400,000. After 1896 profits decreased, and since that time have only totaled 40%. In 1901 the capital was decreased to £80,000. During the year ended March 31, 1912, 43,629 tons of ore, averaging \$10.50 per ton, was produced and, together with 4967 tons of coarse tailing, was cyanided. The value of the bullion produced was £91,811, and the operating cost £91,132. The cost per ton for mining and development is \$6, as there are no ore reserves, the output being gleaned from old stopes, fillings, and stringers. The company has £38,978 of unexpended capital.

### KYSHTIM CORPORATION, LTD.

This company was organized in 1908 to acquire the shares of a Russian company, the Kyshtim Mining Works Co., which owns and operates copper, iron, and gold mines in the Perm district of the southern Urals. The capital is £1,000,000, and £650,000 debentures. The company has made loans of £761,152 to the Russian company for the purpose of reorganizing the work at the mines and smelters. During 1911 the Koniukloff, Smirnoff, and Tissoff mines produced 247,102 tons of ore averaging 3.19% copper. At the new smelting plant at Karabash 218,310 tons of ore was treated, and the production of blister from this plant and the old works was 5020 tons. Of this, 4033 tons was electrolytically refined, producing gold and silver amounting to £55,321, or £13 14s. per ton of copper. The total cost of operation was 15s. per ton of ore, or £34<sup>1</sup>/<sub>3</sub> per ton of blister copper. The ore reserve is estimated to contain 1,699,000 tons of 3% copper ore carrying 2 dwt. gold and 1 oz. silver per ton. A third blast-furnace was started in May at the Karabash plant and a second reverberatory at the old plant to treat flue-dust and fine ore. It is expected that the output of copper in 1912 will reach 7000 or 7500 tons. The Russian company in 1911 made a profit of £172,394 on copper production, £23,439 on the iron works, £29,651 from timber, and £4919 from the sale of pyrite for sulphuric acid manufacture. For expenses £119,135 was paid, £30,033 written off, and £65,200 was paid to the English company. The holders of ordinary shares have as yet received no return on their investment.

### BROKEN HILL PROPRIETARY CO., LTD.

In an editorial of the *Mining and Scientific Press* of August 17, the various works controlled by this company, and its intention to manufacture iron and steel on a large scale at Newcastle, New South Wales, were commented on. The fifty-fourth half-yearly report shows nothing of special note; but general progress has been sound, and the future is bright. Besides mining its own ore, the company is a large purchaser of lead-zinc-silver ores and concentrate, which are smelted at its large plant at Port

Pirie, in South Australia. Some of the zinc concentrate is shipped to Europe, but spelter is being produced at its own refinery. At one time the concentrating mills used to treat about 300,000 tons of ore every six months, but during the term under review only 109,619 tons was dealt with, with the following results:

Lead concentrate produced.....	Tons.	22,406
“ “ “ from 111,733 tons of old		
“ “ “ tailing .....	3,512	
Zinc “ “ from 9455 tons of slime..	3,209	
“ “ “ “ 168,309 tons of resi-		
“ “ “ due .....	46,005	

The sintering of slime has been abandoned, and a flotation process perfected for this product. In all, the flotation plants treated 177,764 tons of old residue and slime. Three smelters worked continuously and dealt with 15,952 tons of oxidized ores, and 62,006 tons of concentrate, etc. Inclusive of purchased ores, the refinery produced the following:

Soft lead .....	Tons.	37,513
Antimonial lead .....	291	
Spelter .....	895	
Blue powder .....	72	
	Ounces.	
Silver .....	1,823,539	
Gold .....	794	

Two of the Ropp roasters were dismantled to make room for Dwight-Lloyd machines, and when this plant is completed the fourth smelter will be blown in. The bag-house for catching lead fume has proved a success. The Mathieson-Hegeler furnace is producing a first-class roasted zinc ore. Six furnaces were in operation at the zinc distillation plant. The balance-sheet shows the following details:

Receipts .....	\$4,300,000
Expenditure .....	3,285,000
Written off .....	84,000
Net profit .....	934,000
Dividends .....	600,000
Added to reserves .....	334,000
Surplus of liquid assets over liabilities.....	3,220,000

Not much information is published in the report with regard to mining operations.

#### BROKEN HILL SOUTH SILVER MINING COMPANY

This is one of the most important companies operating at Broken Hill. It mines and concentrates its ore, but sells concentrate and old tailing to other companies. During the half-year ended June 30, only 2682 ft. of development was done in the mine, mostly at the 1070-ft. level. Driving south was done on the bottom level, 1170 ft. from No. 2 shaft. The Central mine, an adjoining property, intersected an orebody 15 ft. wide close to the South company's southwest corner, at 500-ft. depth. At the 1200-ft. level of the Central, equal to 1225 ft. in the South, the lode increased to a width of 86 ft. within 20 ft. of the South boundary, and is pitching south, making it of importance to this company. The ore reserves in the South mine are about 3,000,000 tons. The following table shows details of the half-year's work:

	Tons.	Containing—	
Ore treated .....	165,532	Silver, oz. ....	617,378
Concentrate produced	26,630	Lead, tons .....	18,652
		Tons.	
Delivery of zinc tailing to Amalgamated Zinc plant.	145,465		
Delivery of zinc tailing to Zinc Corporation.....	17,585		
Costs per ton of ore treated:			
Mining .....	\$3.10	Concentrating .....	0.90
Filling stopes .....	0.36		
Development .....	0.38	Total .....	\$4.74
Receipts .....	\$1,615,000	To reserve fund..	74,000
Expenditure ....	850,000	Surplus of liquid	
Written off .....	28,000	assets over lia-	
Net profit .....	750,000	bilities .....	880,000
Dividends .....	600,000

## Concentrates

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

**HORSE-POWER** totaling 4,699,910 was used by the mining industry of the United States, of which 4,483,807 was owned in 1909 by mine operators, and 216,103 hp., all electric, was rented.

**VANADIUM** added to steel imparts great resistance to shock and the 'fatigue' caused by constant bending. High-carbon vanadium steels make much better tools, such as saws, cutters, and riveting dies. Its use in cast iron is also said to be beneficial. Metavanadic acid has been used to some extent as a substitute for gold bronze in paint. Vanadium chloride is used in fabric printing; and vanadium trioxide in dyeing.

**PRODUCER-GAS** is the gas formed by partial combustion of fuel in a suitable apparatus. The term 'partial combustion,' when used in connection with producer work, may be defined as the incomplete oxidation of the combustible components of the fuel resulting in its complete gasification; and, since some of the combustible components of the gas evolved are not fully oxidized, while others are not oxidized at all, the oxidation of the gases may be carried to completion by burning in a gas-engine or furnace. Gases produced form a mixture in varying proportions of CO, H, O, CO<sub>2</sub>, N, and C<sub>2</sub>H<sub>4</sub>, the combustible components being CO, H, and C<sub>2</sub>H<sub>4</sub>.

**DIRECTORS** of the Victoria Falls Power Co., of South Africa, report "a period of sustained progress during the year 1911, and down to the present time." The total share and debenture capital of the company stands at £7,000,000. The year's business resulted in a profit of £323,000, which, with the balance at credit, makes a total of £360,943. Interest on debentures, and income tax for 1911, absorbed £124,736, and depreciation £61,264, leaving a balance of £174,943. Out of this a 6% dividend was paid, absorbing £129,198, leaving £45,744 to be carried forward. The company has received applications for 52,000 hp., and the Rand Mines Power Supply Co. for electric supply of 67,000 hp. and compressed air of 66,000 hp., making an expected demand of 185,000 hp. When all extensions to stations are completed, the two concerns will have a capacity of 232,000 horse-power.

**COPPER** amounting to 15,035 tons of copper was exported from Chile in 1911, against 17,898 tons for 1910, according to a consular report. Much development was done, and more American capital was invested in Chilean mining interests. The Braden Copper Co. plant of 3000-ton capacity is nearly finished. There are 200 Americans and 2500 native workmen on its payroll. Some rich gold finds were reported from Talca, but nothing definite has been done. The nitrate production amounted to 53,237,315 Chilean quintals, against 50,781,331 in 1910, with the prospect of a greater increase for the current year. There are several new nitrate works, with an annual capacity of 18,000,000 quintals, nearly completed. In 1911, 11,331,904 quintals went to the United States; 19,503,205 to England; 12,216,637 to Germany; 1,762,189 to Belgium; 1,875,327 to the Netherlands; 1,787,501 to France; 824,781 to Mediterranean ports; and 510,530 to Japan. For the first ten weeks of 1912 the exports of nitrate totaled 14,619,132 quintals, against 12,523,931 for that period of last year. Chilean coal imports for 1911 totaled 1,294,118 tons, of which 705,762 tons came from England; and 526,643 from Australia. Only 51,861 tons has been imported from the United States in six years. A number of nitrate works are building oil-burning plants, and the coal imports are therefore likely to decrease. The Chilean Government continued its work of prospecting for new coal and oil

deposits with fair results, the oil discovery in the south promising well. Coal prices were as follows: Cardiff, \$8.76 to \$8.88 per ton; West Hartley, \$7.05 to \$7.54; and Australian, \$6.56 to \$7.54 on board steamer at port of delivery.

**CONVEYOR-BELTS** made of rubber and canvas, with an extra thickness of the former in the centre, last much longer in carrying rough ore than those made of canvas and balata, even when the latter type is sewn with copper. Even the extra first cost of the rubber belt far more than covers the difference between the two makes. For transmission of power the balata belt leaves nothing to be desired, although in driving machinery in hot places, a woven belt is preferable. Leather or rawhide belts should not be used in wet places, as they get too soft and slippery. They are satisfactory when used for driving centrifugal pumps, or when working from a motor. A 3-in. rawhide belt has been known to travel a distance of 3,000,000 miles, in driving a centrifugal pump, before being worn out. In dry or wet elevators, for fine ore or pulp, rubber belts are most satisfactory. A little castor oil is as good a dressing for belts as can be found among the many dressings made. Being a vegetable oil, it does not rot a belt as does mineral oil, and it gives plenty of grip to the surface. Joining belts is done in many ways; the Bristol & Jackson fasteners being secure and are quickly fitted, while rawhide laces last a long time and make good joints, but take a little extra time in lacing.

## Decisions Relating to Mining

Specially reported for the MINING AND SCIENTIFIC PRESS.

### FOREST RESERVES NOT TO BE CREATED BY EXECUTIVE WITHDRAWALS

By an Act of Congress approved August 24, 1912, the President of the United States is prohibited from creating new forest reserves or making additions to existing reserves in the state of California except by authority of an Act of Congress.

Act approved August 24, 1912. (Not yet published.)

NOTE.—This act amends the Act of June 25, 1910, by adding California to the list of states where this inhibition is in force.

### INTERFERENCE WITH OPERATIONS—A QUESTION OF FACT

Where suit was brought by the lessee of a mine against his lessors who were working a block of ground immediately above the lessee's ground, causing his stopes to cave in and making operation impossible, and the evidence was in conflict as to whether such caving was a necessary result of the reasonable and miner-like working of the lessor's ground, the lower court was held in error for directing a verdict for the defendant instead of submitting the questions to the discretion of the jury.

Peterson v. Bullion Beek & Champion Mining Co. (Utah), 126 Pacific, 310. July 30, 1912.

### MINING OPTIONS—RIGHT TO EXERCISE DENIED

Where the Silver Peak Mines, by judgment of a court of law, had terminated options with certain parties and made other arrangements for the development of their properties, which were subsequently consummated, involving the expenditure of vast sums of money and the development of immensely valuable mines, and where many years have elapsed, other persons, claiming to have been in partnership with the original optionees, but who were not made parties to the suits terminating those options, will not be allowed to exercise those options at this late date, particularly where they have failed to show either fraud on the part of the mining company or good faith, ability, and readiness on their own part to perform their contract during the intervening years.

Gamble v. Hanchett (Nevada), 126 Pacific, 111. May 4, 1912.

## A New Dry Concentrator

The accompanying illustration shows in detail the new dry concentrator designed and manufactured by the International Concentrator Co. of 149 Broadway, New York. It is claimed by this company that reference to the article by F. J. H. Merrill, in the July 13 issue of the *Mining and Scientific Press*, and to other papers on the same subject, will show that the faults of other dry concentrators have been overcome by the peculiar and original design of this new table. While it is at present impossible for the company to point to concentrators in use under many varying conditions, experiments at its works in Orange, New Jersey, have demonstrated this concentrator to be successful in the separation of many classes of ore.

The principle of construction is based upon what may be termed a double vacuum, as the construction requires two vacuum chambers (the upper and the lower) having separate but related functions. The operation of the table itself will be readily understood by study of the drawing. Among the many superior features claimed for the concentrator are the following: Constant control of the air force; perfect stratification of the granulated ore on an

unperforated reciprocating table; tailing in process of separation cannot fall again to the table, after once parted from the mineral, as usual in single compartment machines before mentioned; obviation of all unfavorable conditions involved in variation of feed, air force, or speed, peculiar to other machines; definite, uninterrupted, and continuous action permits heavier volume of feed and corresponding increased capacity; operation is dustless, sanitary, and can be conducted by unskilled labor.

The table itself is made of steel, this being thought to be superior to the usual wood construction. Each table weighs, complete, about 1200 lb., and can be shipped set up, or if intended for a destination remote from a railroad, may be shipped knocked down, and ready for mule-back transportation, the heaviest section weighing less than 200 lb. All parts are interchangeable.

## Enclosed Type Air-Compressor

Below is illustrated a new enclosed type, self-oiling, belt-driven air-compressor, the smallest size of a new line being put on the market by the Chicago Pneumatic Tool Co. This compressor furnished the air for operating all air apparatus at the recent annual convention and exhibition of the American Master Mechanics and Master Car Builders Associations held at Atlantic City, New Jersey, June 12 to 22. This is known as the 'Chicago Pneumatic' Class M-CB, having two-stage air-cylinders, 10 and 16 in. diameter, with 12-in. stroke. At its rated speed of 210 revolutions it has a displacement of 576 cu. ft. per minute. Mechanical inlet air-valves of the semi-rotary Corliss type are used, actuated by eccentrics on compressor shaft. Discharge valves are of the Chicago pneumatic air-cushioned poppet type, placed radially in the heads.

This combination insures high volumetric efficiency and

the elimination of valve troubles, as the valves are interchangeable and most accessible for adjustment and renewal. Heads and cylinder walls are completely water-jacketed, and arranged with independent water supply, per-

mitting the use of solid gaskets between heads and cylinders. Frames are full tangye type with bored cross-head guides completely enclosing cross-head bearings. Cranks and eccentrics are enclosed with substantial planished iron casing, enabling complete flood lubrication of main bearings, cross-head, and moving parts by means of automatic gravity lubrication. Inlet valves and pistons are lubricated by large glass sight-feed lubricators on caps of inlet valves, and all valve-gear bearings have extra large compression grease cups. The intercooler is of the steel-shell marine condenser type mounted overhead, provided with composition tubes, baffle plates, and separator drip pockets. Air-cylinders are bolted directly to the tangye frames, and in addition extend down to large sole plates with drip guards all around. Cranks are of the balanced-disc type, pressed and keyed to shaft. The driving pulley is split-keyed to shaft and machined true on its face and edges. It is of unusually heavy design to give the necessary fly-wheel effect. Control is effected by an improved throttling intake controller operated by receiver pressure, capable of close regulation and adjusting the load to meet the air demands, so that the power consumption is reduced to a minimum.

This particular installation also includes a Westinghouse type 'HF' slip-ring induction motor, and a Cutler-Hammer controller with diaphragm attachment arranged to shut down or start up the motor in accordance with the air demands. The combination represents the latest developments in high efficiency air-power practice, and owing to the type of valves is noiseless in operation. The same type is furnished in capacities up to 4000 cu. ft. per minute. Equivalent sizes and capacities can be furnished in short belt drive and motor drive with motor mounted directly on compressor shaft. Further information can be obtained from main offices of the Chicago Pneumatic Tool Co., Chicago, New York, or any branch office.

## Catalogues Received

STANDARD SPIRAL PIPE WORKS, 25 N. Dearborn St., Chicago. Price list of Reinforced Spiral Pipe.

W. S. ROCKWELL Co., New York. 'Rotary Annealing and Hardening Furnaces.' 15 pages. Illustrated. 8½ by 11 inches.

HAYWARD Co., New York. Pamphlet No. 594, 'Hayward Buckets and Digging Machinery.' 8 pages. Illustrated. 6 by 9 inches.

MINE & SMELTER SUPPLY Co., Denver, Colorado. Bulletin No. 25, 'The No. 6 Wilfley Concentrator.' 19 pages. Illustrated. 7 by 10 inches.

POWER & MINING MACHINERY Co., Milwaukee, Wisconsin. Special catalogue in Spanish, 'Milling Machinery.' 112 pages. Illustrated. 6 by 9 inches.

HYATT ROLLER BEARING Co., Newark, New Jersey. 'The Hyatt Way.' Monthly publication of this company, dealing with the Hyatt roller bearing. 8 pages. Illustrated. 6 by 9 inches.

## EDITORIAL

**A**NNOUNCEMENT of a paper on 'Electric Hoists in Headgears,' to be read before a South African Technical Society gives rise to speculation as to whether this might not be worse than a bee in one's bonnet.

**D**ECREASE of the supply of gas from the Kansas and Oklahoma districts is causing much concern in the adjacent regions. The companies are finding it necessary to increase the price from its present level of 25 cents per thousand to domestic consumers, and many operators are beginning to return to the use of coal. The capital expenditure required in making the change will be a tax on industry that might have been met by a sinking fund set aside from the increased profits derived from the use of the cheaper fuel.

**C**ALIFORNIANS will be surprised to learn from the report of Mr. B. S. Butler that, with the exception of Alaska, their state has the record for the highest average content of copper ore smelted, with an average for 1911 of 3.7 per cent of copper. How completely this has become the day of the low-grade producer is well evidenced by the figures for Arizona, 3.57 per cent, and for Montana, 3.13 per cent. Alaska is easily first, with an average content of 19.77 per cent, due to the shipments of high-grade ore from the Bonanza mine.

**E**UROPEAN bankers are reported to hope for Turkish success in the Balkan war, but the cables from the battlefield as yet give little promise of such a conclusion. The victories of the allies are popularly received with joy, since Turkey has never held a high place in popular esteem. The zeal of the allies is indicated by the great numbers of Greek, Bulgarian, and Montenegrin laborers who have already left America to enlist in the armies of their native countries, and the possibility of the principal European powers becoming involved is far from remote.

**J**APAN is not a large producer of the precious metals, though a small steady production has been maintained since early times. More recently, with the introduction of modern machinery and the cyanide process, increase in production has been rapid, the value of the gold output now being double that of a decade ago, while silver production has also increased. The total is still small, \$3,000,000 in gold and \$2,380,000 in silver in 1911, but the wide distribution of the small mines throughout the Empire make them important factors in the economic scheme of a country where wages and living costs are still low, though rapidly increasing.

**P**OLITICALLY this is a peculiar year in that even during the week before election there is general uncertainty as to what the outcome will be on Tuesday. In every presidential election of recent years it has been possible to prophesy the result of the election several weeks before it was held, but this year no one except national committeemen are rash enough to make assertions. The disappointed candidates may draw some comfort from the

recent report that Mr. W. J. Bryan, who has established a lasting reputation as a 'runner-up,' is to build a \$100,000 home on his Texas farm. Evidently defeat has its compensations.

**D**ECISION of Mr. E. S. Farrington, justice of the Nevada District Court of the United States, in the suit of the National Mines Company against the Charleston Hill National Mining Syndicate, of which the technical features were described in the issue of July 13, establishes the ruling that the fault and the vein are parts of one and the same fissure and awards the decision to the National Mines Company. The value of the ore involved in the suit is large, and the case was especially notable for the array of well known geologists and engineers who served as expert witnesses. A suit for an accounting of the profits derived from ore mined by the Charleston company from the National ground will probably follow.

**T**IMBER scarcity in the heart of a forest seems anomalous, but is actually reasonable. The engineer who is accustomed to an ample supply of soft wood for construction and operation purposes is free from the troubles of his colleague in a district where only hardwood timber is available. In Australia as well as in the Philippines the supply of soft wood for building construction is almost entirely derived from the United States, and a house with a galvanized iron roof is regarded as entirely acceptable. Japan and China both take large quantities of Oregon timber annually, and the development of the use of concrete in building construction is a welcome relief to the pressure on the soft-wood supply, since for certain uses, such as the manufacture of doors and window-sash, no general substitute seems likely to be developed.

**R**ESUMPTION of work at the copper mines at Bingham and Ely brings to an end an ill-advised strike with nothing gained for the workman other than what might have been obtained by peaceable means, and indicates the futility of syndicalism. There was no complaint that workmen of these companies were not well paid, the demand for higher wages being based upon the increased profits of the companies derived from the high price of copper. To many minds this will present a degree of reasonableness, while on the other hand it may as reasonably be held that men who are already receiving as much or greater compensation for their labor than is usually paid for the same class of work elsewhere can not expect to receive more pay merely because their employers are making greater profits. If such a principle as this is to be admitted, then the way is open for corresponding reduction of wages when profits are small, and the net result will be to the disadvantage of the laborer who has been striving for decades to shift the accidents and uncertainties of his employment upon the industry rather than upon the individual. The line of progress of industrial development is steadily toward the stabilizing of conditions for the worker, who is less able to bear reverses than is the aggregation of capital which employs him. Any program of betterment for the wage-earner which overlooks this fundamental principle can not lead to ultimate success. The management of the properties concerned is to be congratulated on the effective way in which they have handled a difficult situation.

#### Development of Converter Practice

Less than a half century ago all the copper produced from sulphide ores was converted from sulphide into metal by a tedious and expensive series of repetitions of roasting and smelting processes. Now the use of the so-

called 'bessemer' converter is universal and the successful development of an upright converter, 20 feet in diameter, at the Great Falls smelting plant of the Anaconda company, as described in earlier issues, affords an opportunity for a review of the development of converter practice. The primitive ancestor of the conversion of matte into copper through oxidizing the sulphur by means of a blast of air was the *mabuki* method, practised in Japan from early times. This method had no influence on progress, however, and it was not until after Japanese metallurgists had adopted the modern type of converter that the similarity of its principle of action to that of the *mabuki* method was pointed out. Development had its inception in the pointing out by Henry Bessemer that the removal of the carbon in pig iron could be accomplished by blowing air through the molten mass, as the heat of oxidation of the carbon and silicon would be sufficient to keep the mass molten until the completion of the operation. The analogy with the sulphur in copper-iron sulphides soon suggested itself to metallurgists, and experiments were made by Kupelweisse in 1868 and by Jossa and Lalitin in 1871, with the idea of producing copper from matte in the bessemer steel converter. But, as pointed out by Mr. James Douglas, in his review of converter development, these experiments were dropped when it was found that the copper chilled as it formed and choked the tuyeres, this unexpected result giving rise to the too hasty assumption that the method was impracticable. A few years later John Hollway made a series of experiments and later presented several good papers before the London Society of Arts, describing the results obtained. Elsewhere in this issue we reprint the more significant parts of the first paper, a fuller presentation of which the limitations of our space unfortunately serves to prevent. Hollway so clearly mapped out the general field that his work deserves to be better known by metallurgists, to whom the *Proceedings* of the Society of Arts is comparatively inaccessible, and we accordingly republish it for the benefit of our readers. Hollway points out that the heat generated by the oxidation of the iron and sulphur is sufficient to maintain the mass in a molten state during operation, and that the difficulties are lessened when the active mass is greater; the latter a factor of which the full force has only recently been realized. He further pointed out that the  $\text{SiO}_2$  required to form a slag can either be derived from the silicious lining of the converter or from silicious material thrown into the converter during the progress of the operation, and suggests that in this way quantities of silicious gold and silver ores may be smelted. But Hollway was more impressed with the possibilities of his method as applied to the production of a rich matte from low-grade sulphide ores, having directed his experiments to that end, and after remarking that the ordinary form of bessemer converter is not altogether suitable for this work, proposes the use of pyrite smelting in a modified form of blast furnace. Having blocked out the essential features both of the converting of matte and of pyrite smelting, Hollway was not equally successful in the development of the necessary apparatus. The many accidents of converter operation, now so familiar, served to effectually deter his financial backers, and this brilliant series of experiments came to an untimely end. Shortly afterward, M. Manhes attempted the making of copper from matte in the bessemer converter at his rolling mill at Vedenes, and, having hit on the expedient of placing the tuyeres at such a height that the blast would not chill the metallic copper as it formed, he met with such success that he proceeded to erect a full-sized plant at Aiguilles, about 50 miles north of Marseilles. Here two 3-ton bessemer con-

verters were used, in one of which the matte was concentrated to 60 per cent copper, then transferred and blown to blister copper in the second. It is truly remarkable that so important an advance in the art of copper smelting should be made in a country of so little importance as a source of copper that it does not ordinarily appear in the list of producers, and at a place so obscure. The honors may fairly be divided between Manhes and Hollway. Hollway made a scientific study of a general problem with commendable thoroughness, but unfortunately he slighted the most important possibility of his results, and his experimental work was inconclusive. Manhes, on the other hand, concentrated his attention upon the making of copper from matte, and being able to experiment at his own plant, quickly attained success.

Development of the method now transferred itself to this country. Franklin Farrel followed the lead of Manhes at the Parrot works at Butte, with the assistance of some of Manhes' pupils, so successfully that six converters were soon at work, the scheme of keeping the tuyeres free from copper by systematic punching, initiated at the Parrot, being a material aid to success in operation. By 1890 the advantages of the new method were generally recognized and converters were in use or under construction at Anaconda, Great Falls, Butte, and Ashio, Japan. All these plants used some modification of the upright type of converter, and it was not until later that the horizontal type of converter was first employed in America at the Vivian plant at Sudbury, Ontario. The management of the Copper Queen company had studied the operation of small converters of this type at an Italian smelter at Leghorn and 5-ton converters were constructed for experimental purposes. The purpose of the design of the horizontal or 'Bisbee' type, as it afterward came to be known, is to obviate trouble from the chilling of the copper at the tuyeres by placing them in a horizontal row on one side so that by tilting the converter the tuyeres may be kept above the level of the accumulated copper. For a variety of reasons this type of construction strongly appealed to metallurgists, and its use became so general that it was not long before only a few plants retained the upright construction. Among these was the smelting plant at Great Falls, where the staff not only adhered to the type, but developed it from 7 feet in diameter to 20 feet in diameter, and have earned the right to attach the name of Great Falls to this form of construction, originally known as the Parrot type. Meanwhile the changing flux of conditions had led, through a series of experiments which would require too much space for mention, to a general use of Hollway's method of throwing in silicious material through the mouth of the converter, and it was found useful to observe his suggestion that the difficulties of operation are less when the mass of material treated is greater. Messrs. Pierce and Smith accordingly devised a large horizontal converter with a basic lining which could be successfully used and was generally adopted at the plants of the American Smelting & Refining Company. The original form of this converter was mechanically imperfect, and exhibited in exaggerated form the drawbacks of the Bisbee type. The shape of the lining in the horizontal type is structurally imperfect to resist the strains resulting from changes of temperature and the effects of mechanical abrasion. The shape of the lining in the upright type, a vertical cylinder, is mechanically good, and as a result this type of construction is being adopted at the Cananea, Copper Queen, Calumet & Arizona, and Arizona Copper Company plants, and at the El Paso and Hayden plants of the American Smelting & Refining Company as well. The use of large upright converters with basic lining

decreases the cost of converting nearly to the irreducible minimum of the power cost for air, and the minimum of labor for charging, pouring, and punching of tuyeres, and it seems improbable that any further great advance will be made, though metallurgists will continue, as in the past, to constantly improve their practice within the limits of the basal definition of metallurgy as the art of making money out of ore. Meanwhile Messrs. C. W. Goodale, H. A. Wheeler, and the staff of the Great Falls plant have the satisfaction of knowing that 'sticking to the job,' in the words of Mr. E. P. Mathewson, does bring gratifying results.

### Progress in Institute Affairs

Admirable progress is being made in the readjustment of the affairs of the American Institute of Mining Engineers. The committee, consisting of Messrs. J. W. Richards, Charles Kirchhoff, and C. F. Rand, appointed at the New York meeting on October 7, to formulate a plan for the future government of the Institute by one body instead of by a council and board of directors as at present, have prepared a draft which was submitted for discussion at the meeting at Cleveland on Wednesday, but no report of the conclusions attained had reached us at the time of going to press. In the main, however, the report of the committee follows the line of the generally excellent set of amendments submitted by Messrs. C. R. Corning and G. C. Stone at the New York meeting, and published in our issue of October 19, but provides for a Board of Directors, consisting of 24 members, to control all the activities of the Institute. An amendment to the articles of incorporation provides that the nine Directors who hold office in February 1913 shall, together with the 15 senior members of the Council, constitute the new board, and suitable provision is made for retirement until 8 members of the board can be regularly elected each year. The board shall elect from its members an executive committee of five, of whom three shall constitute a quorum to transact business with limited powers between regular meetings of the board. Thus the advantage of geographical representation on the board of management will be secured without making it too difficult to carry on the ordinary business of the Institute, since eight members constitute a quorum of the Directors. This will apparently be a distinct gain to the Institute, for the relationship of its governing bodies and officers is thus made commendably clear and should result in much more effective interest in Institute affairs. The general features of the amendments already published are followed in the substitution of letter ballots for the present system of voting by proxy, the appointment of a business manager, the appointment of a committee on publications, and the provisions for the formation of local sections. Amendments to the by-laws are hereafter to be made by the Board of Directors. A proposal to create a new class of membership, to be known as Fellows of the Institute, who may as a body discuss and by a majority vote express their opinion upon pending legislation affecting the mining and metallurgical industries was to be submitted for discussion at the Cleveland meeting, and comment upon it is therefore delayed. The meeting at Cleveland was well attended, interesting papers were presented, and a good discussion followed. It is evident that the fears entertained for the future of the Institute were groundless, and the same is true of the impression that has prevailed in some quarters that the differences existing between those taking part in the reorganization were other than the ordinary differences of earnest men striving for a common purpose. We are glad that the future looks so bright for the continued success of the organization.

## Compressed-Air Hoisting at Butte

By THOMAS T. READ

The substitution of compressed air for steam in operating the hoists at the numerous shafts of the Anaconda Copper Mining Co. at Butte, Montana, is perhaps the most interesting event of recent years in power-plant engineering. The relative advantages of compressed air and electric power for this work have been vigorously discussed by mechanical and electrical engineers. But differential equations defining the relations of volumes, pressures, and temperatures are matters concerning which the average engineer knows little and cares less, and I propose in the following paragraphs to present merely a general description of this interesting and important power-plant, avoiding so far as possible all points of dispute, and hoping thereby to avoid being drawn into a controversy with which I have no concern.

The hoisting shafts of the Anaconda Copper Mining Co.

river. This is transmitted 130 miles from Great Falls to Butte, at 100,000 volts, and is transformed to 2400 volts for use at the mines. The cost of electric power is \$35 per horse-power-year, and when the full supply of electric energy became available about two years ago, it was at once decided to use it in place of coal, as a source of power supply. The question remaining to be decided was what medium of transmission of this energy could be employed to the greatest advantage.

Several methods of doing this were feasible. Electric hoists might have been placed at the shafts, this making the Great Falls plant the central station. But so simple an arrangement as this would have caused fluctuations in the power transmitted through the long transmission line that would have resulted in peak-loads of prohibitive magnitude, and to equalize the consumption of electric power some

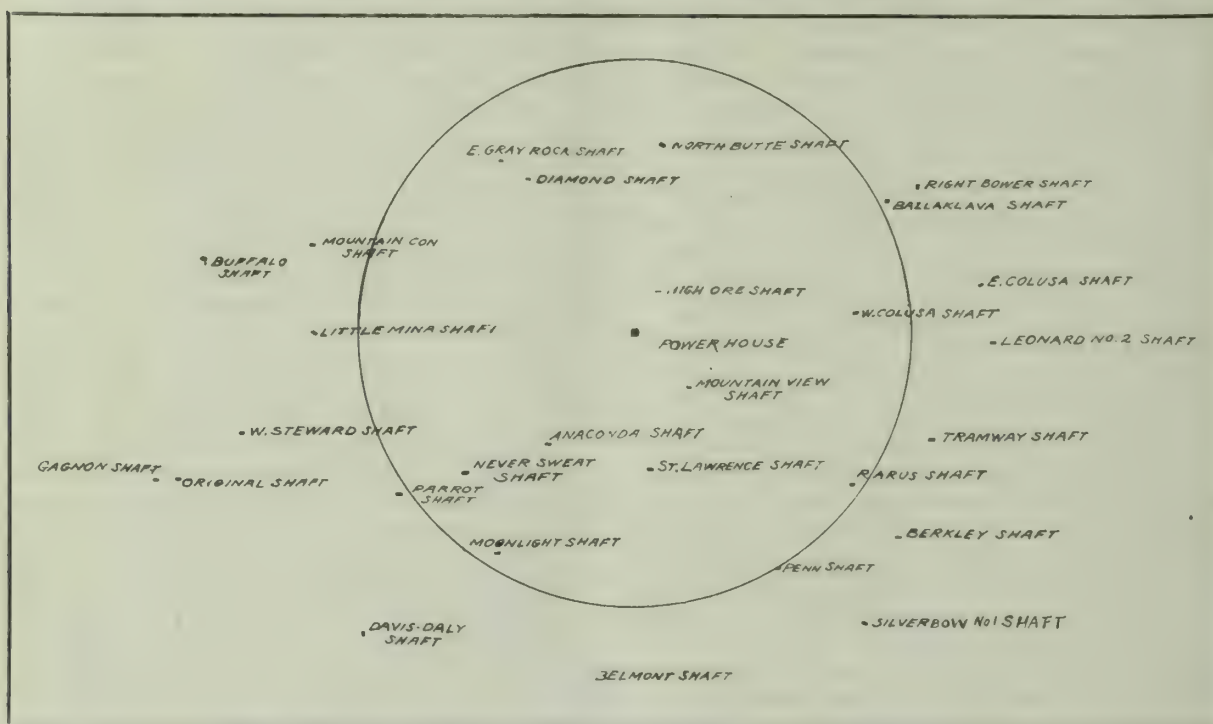

FIG. 1. HOISTING SHAFTS OF THE ANACONDA COMPANY, BUTTE. THE CIRCLE HAS A RADIUS OF  $\frac{1}{2}$  MILE.

are scattered over the hills north of the town of Butte, and are at elevations of 5600 to 6200 ft. above sea-level. The new central power-house is at an elevation of 6080 ft. The relative position of the different shafts is shown in Fig. 1, and the circle, drawn with a radius of  $\frac{1}{2}$  mile and with the new power-house as a centre, serves to indicate the distances involved. At these shafts steam-driven hoists, rated at 3000 hp., and hoisting 5-ton skip-loads of ore at the rate of 2800 ft. per minute, have been in operation. Each shaft is also provided with a smaller hoist, locally known as a 'chippy,' for handling timber and general supplies for work underground. Hoists are operated on both shifts, the actual time which the main hoist is in motion being, according to B. V. Nordberg, about 5 hours out of the 24. Each shaft was provided with a boiler-plant, with its necessary labor, and coal, costing \$4.50 per ton, was distributed to the shafts. The advantages of operation from a central power-station which could counterbalance the fluctuations in the power requirements of the individual hoists is evident. The recent growth of hydro-electric power development in Montana has made available at the mines an ample supply of electric energy, generated at the plant of the Great Falls Power Co., near the town of that name, on the Missouri

form of compensating device would therefore have been necessary. Storage batteries are not satisfactory for mine work; the loss of energy in converting electric energy into chemical energy and the latter to electric energy again, the cost of construction and maintenance, and their constant deterioration has led to a discontinuance of their use for this kind of work. The Ilgner transformer has given good results in Germany and elsewhere when employed for hoists which are in nearly continuous operation, but cannot be utilized to advantage on hoists which are idle a large part of the time. It was therefore decided to use the electric energy to drive air-compressors at the central station, the air being stored in a system of receivers and air-lines which distribute it to the hoists. It is then reheated and used in the re-built cylinders of the old steam-hoists. I will first describe the power-plant, as its advantages can then more easily be indicated. The plant is still under construction, but for the sake of clearness and convenience I will describe it in the form it will have when the construction work now under way is completed.

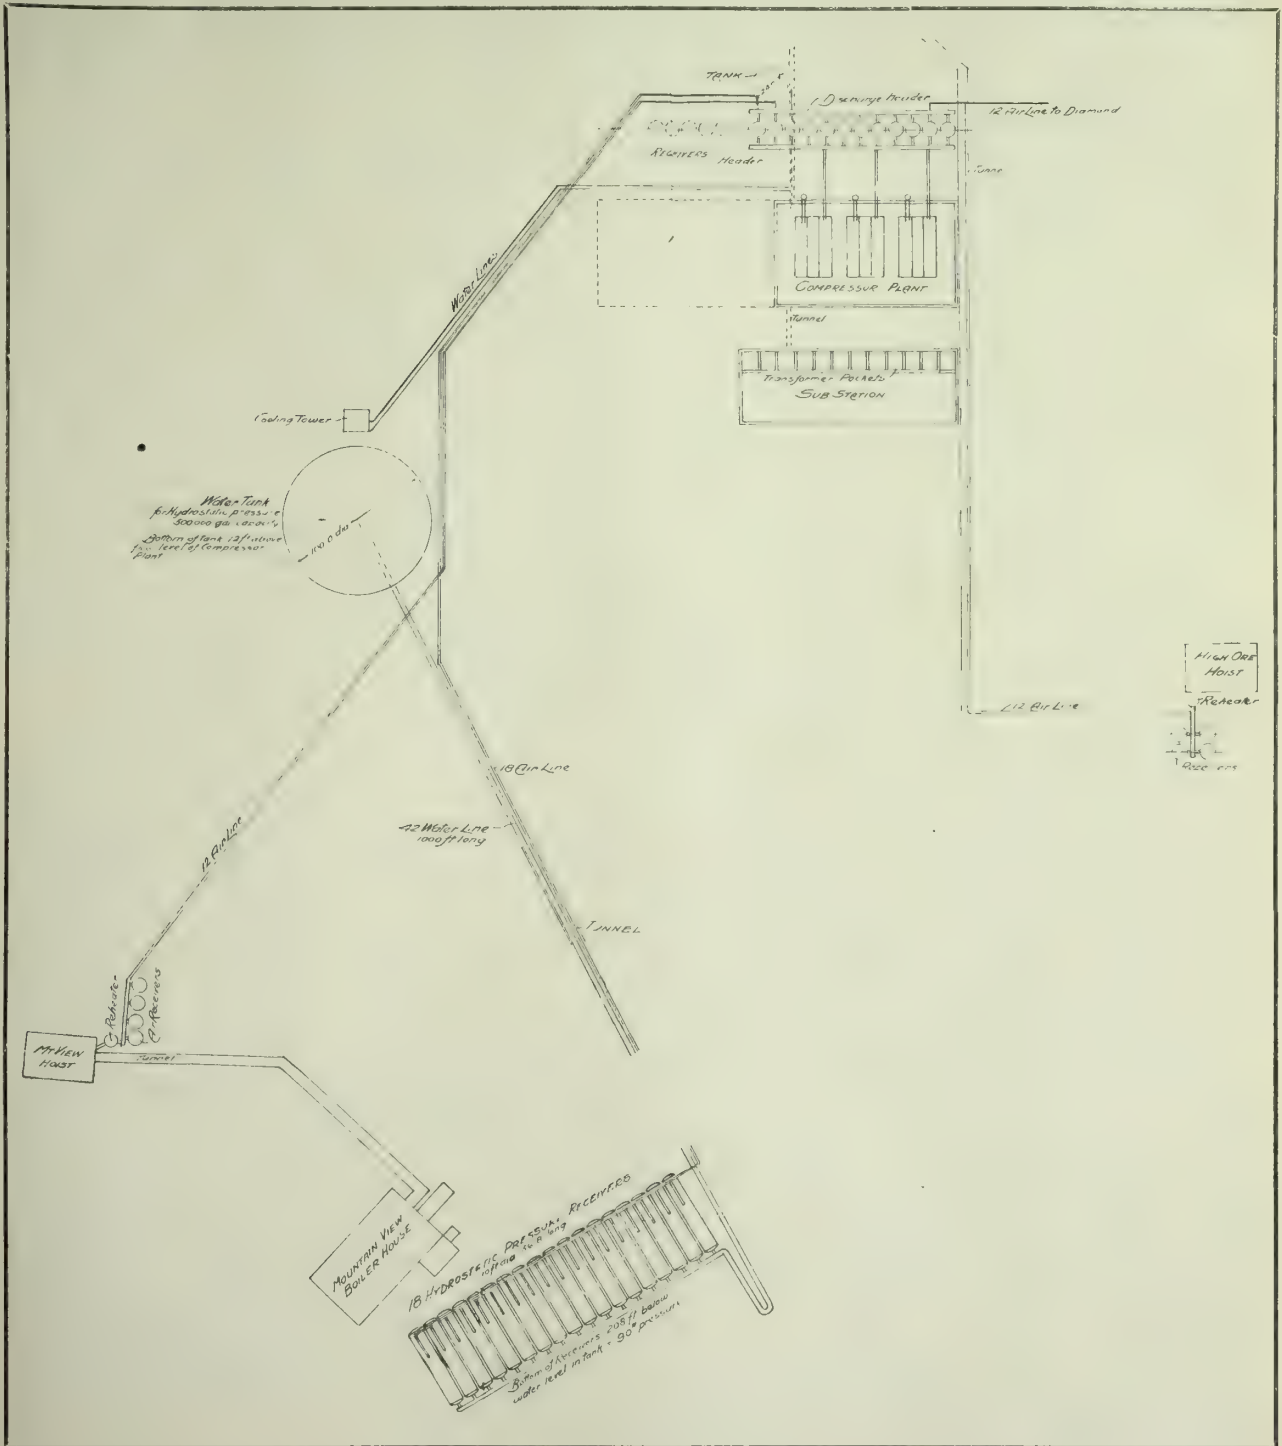

The electric energy from Great Falls is delivered at the transformer house, seen in Fig. 2, and transformed to 2400 volts. Six Westinghouse A. C. synchronous motors, of

1200 hp. each, drive 6 Nordberg cross-compound air-compressors having 30 and 50-in. diameter cylinders, each compressor being rated at 7500 cu. ft. per minute. Three of these compressors are fitted with variable-capacity valve-gear and the other three are of uniform capacity. The air is compressed to 23 lb. in the low-pressure cylinder, passes through the intercooler, and is compressed to 90 lb.

pressors will serve to meet all the ordinary requirements of work. Since construction work was started, the daily output of the mines has been increased from 12,000 to 15,000 tons per day; the load on the power-house is therefore somewhat dependent upon the market price of copper.

The air from the compressors is delivered to a battery of 18 vertical cylindrical receivers 10 by 30 ft. and of a ca-

short distance above the Leonard shaft. These receivers are connected by a 42-in. water-line (having a 25-ft. loop at the bottom for safety) with a 500,000-gal. water-tank on top of the hill a short distance south of the power-house. When the water in the tank is  $8\frac{1}{2}$  ft. deep it stands 208 ft. above the receivers, thus giving a pressure of 90 lb. per square inch. When the air consumption by the hoists exceeds the supply from the compressors the water flows down into the lower receivers, displacing the 66,840 cu. ft. of compressed air which they contain (equivalent to 568,000 cu. ft. of free air). This storage system not only serves as an equalizer of the load upon the central power-house, but in the event of the total failure of the electric power, the stored air will serve to operate each hoist for twenty minutes, thus making it possible to hoist out the men at work underground. It should be noted that this reserve remains available indefinitely until it is used up; whereas with an Ilgner transformer it would be necessary to utilize the power of the transformer at once, perhaps before it would be possible to collect all the men at the stations.

Four air receivers are provided at each hoist. The air on its way to the hoist passes through a sectional surface heater of special design, 50 in. diameter and 25 ft. high. The heat is furnished by a 50-hp. return tubular boiler, giving steam at 200 lb. pressure and serving to reheat the air to 300°F. The coal used for reheating the air amounts to  $\frac{1}{3}$  lb. per horse-power hour. As the steam hoisting-engines were operated at from 120 to 150 lb. steam pressure and the air is at 90 lb., the hoists have been altered by removing the old steam cylinders and replacing them with larger ones, this being the only change necessary. The valve-gearing of these cylinders is so constructed that the full power can be turned on to secure the necessary acceleration, and when the skip begins to approach, the top the speed of engine is checked by compressing air in the cylinders, which is accomplished by means of a compression lever operated by the engineer and by which means the exhaust valves are made to cut off at any desired part of the stroke, thus compressing the air in the cylinders and delivering it back into the main system. The speed of engine can also be checked by reversing the valve gear and compressing air in the cylinders, which is drawn in through the exhaust pipe and delivered into the main system as before. The energy which would ordinarily be wasted in useless friction on the brake shoes is thus returned to the storage system to be utilized on the next trip. The valve mechanism required for this purpose is extremely simple, and the hoist men are stated to prefer to operate the air hoists rather than the steam-driven ones. It will be noted that this system required the minimum amount of change in the present equipment. In the steam hoists, many of them of the flat-rope type and large enough to operate to a considerably increased depth, no further changes were necessary than the replacing of the cylinders. If electric hoists had been employed it would not only have been necessary to discard the steam hoists, but the surface plant would have required reconstruction, since the floor space required for an electric hoist greatly exceeds that of a flat-rope hoist.

Many of the advantages of the compressed air system in meeting the governing conditions at Butte are evident from the description. It must not rashly be inferred that compressed air, like a patent medicine, is good for all hoisting troubles. In this case, however, where a large number of hoists are to be operated from a central power plant, compressed air forms a useful means of power transmission because it is elastic and can be stored. In this way the occurrence of high peak loads can be automatically and mechanically prevented. This is aided, of course, by arranging the regular hours for hoisting at the various shafts so as to distribute it throughout the day, as far as possible. The hoists at the Mountain View, Diamond, High Ore, West Gray Rock, Leonard, Tramway, and Pennsylvania shafts have already been converted to the use of compressed air and 7000 tons per day is now being hoisted by the compressed-air hoists. The other hoists will be converted one

at a time, as it is necessary to interfere as little as possible with the regular output of ore. The theoretical efficiency of the plant is stated as follows: motor efficiency, 95%; mechanical efficiency of compressors, 90%; efficiency of air compression, 83%; efficiency of hoist, 50%; total efficiency without reheating, 35.48%; efficiency after reheating, 53%. Thus 1.88 hp. of the compressor motor is equivalent to 1 hp. at the hoist. In closing, I wish to express my obligation to John Gillie, C. W. Goodale, B. H. Dunshee, and W. J. Lilly for the facilities which they so kindly accorded for observation of the plant and securing data regarding it.

## Record-Breaking Output of Copper

The year 1911 was one of prosperity for the copper industry, both smelter and refinery outputs being the largest in its history, according to a report by B. S. Butler, just issued by the United States Geological Survey as an advance chapter from Mineral Resources of the United States for that year. The average price of copper for 1911 was 12.5c. per pound, slightly below the price of 1910, but near the close of the year the price advanced, the average for December being 13.71c. per pound. Metal-market conditions continued to improve until the average price had risen, in July 1912, above 17c. per pound, the highest price since the panic of 1907.

The smelter production of copper in the United States in 1911 was 1,097,232,749 lb., or 56% of the world's production, but while the production surpassed that of 1910 by 8,995,317 lb., the value of the 1911 output was but \$137,154,092, compared with \$137,180,257 for 1910. The following table shows the mine and smelter output of 9 leading copper-producing states and Alaska for 1911:

PRODUCTION OF COPPER IN LEADING STATES IN 1911.  
IN POUNDS

State.	Smelter returns.	Mine returns.
Arizona .....	303,202,532	306,141,538
Montana .....	271,814,491	272,847,705
Michigan .....	218,185,236	291,840,201
Utah .....	142,340,215	146,960,827
Nevada .....	65,561,015	67,377,518
California .....	35,835,651	36,316,136
Alaska .....	22,314,889	27,267,878
Tennessee .....	18,965,143	18,850,276
Colorado .....	9,791,861	8,024,488
Idaho .....	4,514,116	5,152,937

In 1911 twenty-one states and territories contributed to the copper production, but the three leading states (Arizona, Montana, and Michigan) produced 72% of the total output. Arizona produced more than 27% of the output for the year, Montana slightly less than 25%, and Michigan nearly 20%. Utah took fourth place, with an output of 13% of the 1911 production. The six leading states in 1911 (Arizona, Montana, Michigan, Utah, Nevada, and California) produced 94.4% of the output for that year, and the same states have produced 95% of the total output since 1845. Alaska produced the highest-grade ore in 1911, the average yield being 19.77% of copper; California was second, with 3.67%; Arizona was third, with 3.57%; and Montana was fourth, with 3.13 per cent.

SIEVE tests made on the pulp from ore crushed at the Lane mill works, Cue, Western Australia, from the Chunderloo gold mine, Yalonginda, W. A., showed the following result: Sand passing 40-mesh, 99%; 60-mesh, 97%; 80-mesh, 94%; 100-mesh, 90%; 150-mesh, 81%; and 200-mesh, 67%. The height of the overflow used on the Lane mill to obtain this extremely fine product was 7 in. above the mill track. It seems marvelous that such a fine pulp could be obtained in one operation. The ore as it comes from the mine is crushed to about  $1\frac{1}{4}$  in. and thence passes through the Lane mill. This fineness was obtained when grinding at the rate of 36 tons per 24 hours. The ore contains 2% of copper.

# Treating Sulphides in the Bessemer Converter

By JOHN HOLLWAY

\*When metals are extracted from their ores by fusion, the necessary heat is always obtained by the burning of coal, coke, or other form of carbon. But sulphides can be made to burn in air, and the metallic sulphides, consequently, are natural combustible minerals. My object is to prove that they can be utilized as sources of heat in certain metallurgical operations. The most important of the mineral sulphides is pyrite, with which are frequently associated sulphides of copper and arsenic; silver and gold are usually present in larger or smaller quantities. When pyrite is roasted in the open air, an increase of temperature takes place in its mass, so that the oxidation continues without the application of external heat. This operation is carried on in Spain and other countries, where vast quantities of cupriferous pyrite are exposed in heaps for several months to a slow process of combustion, which gradually converts the sulphide of iron into ferric oxide. A similar combustion is effected in the pyrite burners of the sulphuric acid manufacturers, the solid product of the operation being the so-called 'burned ore,' an impure peroxide of iron. Other important sulphides are those of lead, zinc, and antimony. Sulphide ores of copper, lead, and zinc are usually roasted to render them reducible in the furnace and to make their non-valuable constituents capable of combining with the fluxes used, the requisite heat being always obtained by the combustion of coal or similar material of organic origin. This process of roasting extends over a considerable space of time, and the heat evolved by the oxidation of the sulphides is never very manifest at any period of the operation. The sulphur and metals frequently burn to waste, because the utilization of the heat resulting from their burning has not hitherto been considered a subject of much importance. If, however, a rapid current of air is forced through molten sulphides, the maximum temperature of the combustion is attained, because all the oxygen of the air driven in is then utilized for oxidation, and the operation is concentrated into the space of a few minutes instead of occupying many weeks, or in the case of cupriferous pyrite, many months.

By calculation the comparative temperatures produced by the oxidation of the principal sulphides can be found. The data thus obtained indicated to me that the oxidation of sulphides could produce sufficient heat to render their smelting a self-supporting operation, and in consequence several experiments were made by forcing a current of oxygen from a gas cylinder into molten sulphide of iron contained in a fire-clay crucible. The tuyeres used were porcelain tubes and the stems of common clay pipes. When the current of gas was directed upon the surface of the mass, an intense incandescence with a violet light was observable, showing the high temperature resulting from the oxidation. Upon dipping the tuyere into the sulphide the temperature visibly increased, and the oxide of iron formed acted energetically upon the silica of the fire-clay; but the contents of the crucible soon became viscous in consequence of the absence of sufficient silica to form a fusible slag.

The experiments were continued on April 22, 1878, and larger crucibles used; the sulphide of iron was acted upon by a current of air, sand being added during the oxidation. Matte and slag were obtained. The sulphide of iron was made by fusing cupriferous pyrite in a steel melting-furnace, the fire of which was allowed to burn down as soon as the oxidation commenced. When the blast of air was turned on, the tuyere was dipped into the contents

of the crucible, and the blowing was continued for over 30 minutes. Although the whole of the oxygen was probably consumed, yet the oxidation had not proceeded far enough to concentrate the matte to any extent. About half the iron was removed as ferrous silicate, in which was found 0.104% of copper, and the separation of the matte from the superincumbent slag was very distinct. It was evident that to enable the oxidation to take place with sufficient energy, it would be necessary to introduce the air very rapidly, and, after some further experiments, made also with crucibles, which showed that pyrite could be melted by the heat evolved by its own oxidation, a trial was projected with a bessemer converter, because a rapid transmission of air could be thus obtained, and several experiments were accordingly made during July 1878.

The plant employed consisted of an ordinary cupola, 4 ft. diameter at the tuyeres, and 5 ft. above, having eight tuyeres, four being 3 in. diameter and the remaining four 4 in. diameter. A ladle for conveying the molten metal to the bessemer converter; and a bessemer converter, capable of treating 6 tons of crude iron at a time, lined, as usual, with gannister, and supplied with cold blast. The engines for supplying the blast were two cylinders of 42-in. diameter and 4-ft. stroke, working at about 45 r.p.m., at an average pressure of steam in the boilers of 73 lb. per square inch. The pyrite was put into the cupola with coke and treated like pig iron. When at each operation the cupola was tapped, the molten protosulphide was run into a ladle and thence into the converter.

In the first of these experiments, which took place July 10 and 11, 1878, about five tons of molten sulphide was blown for half an hour in the same manner as a charge of bessemer iron. After thirty minutes' blow the contents, consisting of silicate of iron and matte, were turned out of the vessel. No sand had been thrown into the converter, therefore the gannister lining was energetically attacked by the oxide of iron. The product was quite liquid when run from the vessel, the slag crystallizing on cooling in splendid crystals of ferrous orthosilicate. In the next experiment, sulphides containing 3.4% of copper yielded, after a quarter of an hour's blow, a matte containing 46% of copper, and the destructive action upon the gannister lining was greatly mitigated by throwing sand into the converter.

Six experiments were made on July 17 and 18. The pyrite used contained 2 to 3% of copper, 1.5 oz. of silver, and 3 gr. of gold per ton. Owing to the small quantity of sulphide employed in each of these experiments, the blowing had to be of very short duration, and great care was also necessary to avoid overblowing. To obviate this the blowing had to be arrested earlier than would be necessary to produce a matte containing the desired percentage of copper; but in operating with larger quantities of sulphide there would not be the same difficulty. The spectroscopic phenomena were observed through a six-prism spectroscope. The six experiments were all arranged and the duration of each blow in the bessemer previously settled; and the first, second, and third experiments were so carried out; the fourth was intentionally overblown, in order to observe the changes in the spectrum, and the result of these observations was that in the fifth and sixth experiments the blow was arrested at the moment indicated by the disappearance of certain lines in the spectrum.

The increments in the temperature of the gases at the mouth of the converter were measured by means of one of Siemens' differential pyrometers. The pyrometer was 8 ft. long, with platinum leading wires from the platinum spiral to the terminals. The end exposed to the gases was protected for 1 ft. 6 in. of its length by a porcelain tube 2 ft. long, and the next 2 ft. by loam placed around the iron tube of the pyrometer. The indicated temperature was

\*Extracts from a paper entitled 'A New Application of a Process of Rapid Oxidation by Which Sulphides Are Utilized as Fuel,' presented before the Society of Arts (London), February 14, 1879.

always below that actually obtained, as the fire-clay coating protecting the exposed stem of the pyrometer retarded the transmission of heat.

The gases were sampled by means of a fire-clay bell, connected with  $\frac{1}{2}$ -in. iron tubing, protected by clay from the hot sulphur vapor. The iron tube, at a distance of about 20 ft. from the converter, had inserted in it two pieces of brass pipe, to which were connected, by india-rubber tubing, two glass tubes for taking the gases. The free ends of the gas tubes were connected through a T-piece with a powerful aspirator holding 20 gal. of water. By turning a tap and shutting off the water-cock of the aspirator, both tubes could be filled with identical samples of gas evolved from the converter at any given moment. The sublimate appeared in the glass tubes about three seconds after turning the taps. To avoid any interruption in the experiments, two converters were fitted with similar appliances, both pyrometers being connected with the same instrument, but only one converter was used.

In the first experiment the blow occupied 17 minutes, during which period 14 cwt. of red sand was added. The amount of sulphide introduced into the vessel could not be exactly ascertained. The mean pressure of blast was 20 lb. per square inch. The phenomena at the mouth of the converter were remarkable. At the beginning dense white fume issued from the mouth of the converter, colored in varying tints by the volatile metals present in the incandescent state, affording a brilliant spectrum containing a great number of bright lines. When the temperature rose and the lead was in great part expelled, the flame showed less 'body' and was of a bluish-green color, possibly from the presence of minute quantities of zinc and copper. The blown product of the experiment was emptied into ingot molds and allowed to cool. When cold it was found to consist of three zones, the upper one being the slag proper, the central zone a mixed product of slag and matte, and the lowest a matte free from silica. The specific gravity of the matte was about 4.8 and the slag about 4.1. The products of the experiments gave, upon analysis, the following results: Slag, FeO 53.30%,  $\text{Fe}_2\text{O}_3$  3.00%, copper combined with sulphur 0.16%, sulphur 3.39%, silica 29.90%. Matte, iron 57.10%, copper 15.85%, sulphur 21.96 per cent.

The second experiment was similar to the first, but about 30 cwt. of fused sulphide was used. The sand added was about 14 cwt., which was thrown in, as in the first experiment, and there was, as before, an intermediate matte. The slag was dense, black, and very crystalline; it showed a peculiar radiated structure at the edge near the iron molds, caused by the sudden chill. The zones were not horizontal, but were more or less conical, as owing to the sudden refrigeration of the mass the denser particles had subsided last in the central portion which remained fluid longest. The analyses of the slag and matte obtained are as follows: Slag, FeO 54.62%,  $\text{Fe}_2\text{O}_3$  3.71%, copper combined with sulphur 0.22%, silica 30.05%. Matte, iron 56.05%, copper 16.59%, sulphur 23.47 per cent.

In the third experiment the charge was more fully blown. The sulphide used was about 25 cwt. and the sand added about 14 cwt. The blast pressure was 20 lb. per square inch, and the blow occupied 17 minutes, which was somewhat too long. The separation of the slag from the rich matte immediately beneath it was very distinct. The analyses of products in this experiment are as follows: Matte, sulphur 22.22%, iron 12.56%, copper 62.36%. Average of the slag, metallic iron 49.30%, metallic copper 1.55%, silica 29.55 per cent.

In the fourth experiment the charge was overblown by about six minutes. No sand was added in this blow; about 1 to  $1\frac{1}{4}$  tons of fused sulphide was used. The product was apparently homogeneous in composition and gave on analysis: Silica 34.34%, FeO 25.10%,  $\text{Fe}_2\text{O}_3$  33.83% (= 43.27% metallic iron), copper oxide 2.39% (= 1.91% copper). This slag is less basic and far less crystalline than those ordinarily produced, and the copper exists principally as oxide. As soon as the sub-sulphide of copper began to burn, a splendid emerald-green flame suddenly appeared,

lasting about a minute, and all the lines except those of copper and sodium left the spectrum. During the last few minutes of the blow the mouth of the converter was dull and without flame.

The sixth and last experiment of this series was made upon about 20 cwt. of the fused sulphide; about 11 cwt. of sand was thrown in with a shovel during the blow, which lasted 11 minutes. A central zone of mixed matte and slag was obtained, as in the first experiments of the series, and its composition was somewhat similar. It is of interest to observe that this contained neither silver nor gold, which were concentrated in the rich well-separated matte. Slag, copper 0.42%, FeO 67.52%, silica 26.22%, sulphur 2.06%. Matte, copper combined with sulphur 59.71%, iron 13.16%, sulphur 21.94 per cent.

During the preliminary melting of the pyrite in the cupola, the flame seen at the charging door of the cupola exhibited brilliant colors, continually changing in tint. This flame brightly illuminated the visible spectrum. The greater part of the lead was volatilized during this preliminary melting. Indications were, besides, obtained of the volatilization of sodium, lithium, and thallium. The flame of sulphur and that of carbonic oxide give no distinctive lines, neither does arsenic volatilized as arsenic trioxide; hence no indication of the presence of these substances was to be expected, and zinc was probably not present in this flame in the form of vapor. The spectrum flame from the bessemer converter during the blow was a brilliant one. The lines of sodium, lithium, and thallium were recognizable, but the majority of the lines are of (as yet) unknown origin, though they are the most important, since the changes furnish indications of the progress of the chemical changes taking place in the vessel. Some of these unknown lines are those which were employed as test lines. No lines of lead were observed, nor of copper, except in the fourth experiment, in which all the lines except those of sodium disappeared about six minutes before the 'turn-down.' The charge took longer to melt in the cupola than a corresponding weight of pig iron under the same circumstances, but, when once molten, the sulphides formed a mobile limpid liquid.

Whenever during the experiments the converter was tipped forward the  $\text{SO}_2$  poured out into the pit and made itself apparent by its strong odor. When the converter was in position, however, and the blast on, the smell was scarcely perceptible in the close vicinity of the flame in consequence, doubtless, of the rapid convection of the hot gas. The lining of the converter, after the six blows, was found to be not very materially acted upon, and therefore the reserve converter was not required. The products of the experiment which remained for examination consisted only of slag and matte and a few samples of the gases evolved. The sulphur and sublimes were principally lost in the cupola, which, as before mentioned, was only used for convenience. In practice, the volatilized substances would be collected in flues.

Further experiments were made on November 1 and 2, also with a bessemer converter. To start the oxidation, about two tons of fused sulphide was run into the vessel, which was then brought into position and the charge was blown for about five minutes without any addition. As the heat of mass increased, four tons of cold pyrite was thrown into the converter, gradually, in large lumps, together with 9 cwt. of sand containing over 16% of moisture. Although a large quantity of heat was expended in expelling the sulphur from the cold pyrite and in the expulsion of the water from the sand, yet the contents of the converter were maintained perfectly liquid by the heat of oxidation. After blowing some time, half the charge was tipped into the ladle, and, after the converter had been again placed in position, 18 cwt. more of pyrite was added, in lumps, and 3 cwt. more sand. After a short time the blowing was discontinued and the contents run out into the ladle.

During the experiment sulphur vapor burned at the mouth of the converter and phenomena were observed simi-

lar to those previously cited. It was proved to those present that the smelting of pyrite can be made a self-supporting operation, and that copper matte, silicate of iron slag, volatile sublimes, and  $\text{SO}_2$  can be obtained without the employment of any extraneous fuel other than that employed in producing the blast. Another experiment of a similar nature had been previously attempted, but the addition of cold and wet raw material too early in the operation caused too great a reduction in the temperature, and the chilled contents of the converter had to be extracted by melting with coal. This refrigeration will be readily understood when the heat rendered latent by the fusion of the bisulphide of iron is taken into account, besides which large quantities of gas left the liquid mass at a red heat, and were not utilized to heat or to drive off sulphur from the raw material.

These experiments were carried out with an ordinary bessemer plant, but, for many reasons a bessemer converter is not suitable for the reduction of cold pyrite to matte, nor has it any arrangements for allowing the matte to accumulate out of the reach of the blast. Upon running the molten mass from the ladle into one of the ingot molds, the slag ran in a thick cylindrical stream of perfect continuity, falling without noise a distance of some feet into the liquid portion below. This lasted five minutes, and resembled the effect produced by illuminating a continuous column of liquid by a ray of light passed along its axis.

Further experiments with a bessemer plant were made on February 5, at which Prof. Roscoe and other friends were present. The first experiment was accidentally overblown, besides being chilled by the addition of more than the calculated quantity of sandstone. In attempting to continue the operation by the addition of lumps of pyrite, the strong current of air traversing the silicate of iron chilled it, and caused the mass to set in the vessel. It was partly extracted by the aid of coal, and partly by means of rods. About 2 cwt. of coal was now thrown into the empty vessel, and lumps of cold pyrite were added. The blowing being resumed, liquid sulphides accumulated on the tuyere hearth of the vessel, and pyrite and sand were continuously introduced during eight hours. While the operation was in progress a steam-pipe burst, and the blowing was discontinued for 20 minutes. The contents of the vessel, however, remained fused, and the operation was continued without any difficulty. During the 8 hours the blow lasted, a continuous jet of sulphur vapor burned at the mouth of the converter, where it came in contact with the external air. Round the edges, particularly at the base, the flame was of the well known blue color of burning sulphur; but the body of the flame appeared of a greenish tint. This was due to the yellowish brown color of the unburnt incandescent vapor of sulphur and the blue color of the sulphur flame; viewed through a small direct-vision spectroscope, many absorption bands were seen occurring at apparently regular intervals, from the red to the violet. Dr. Watts believes the spectrum to be principally due to the sulphur. Over 8 tons of sulphur vapor was probably burned in the eight hours, and about 18 tons of raw pyrite was treated.

The slag formed in the experiments principally consisted of a silicate of protoxide of iron, but contained some sulphur as sulphide of iron. If, after the matte has been separated from the slag, the latter is further bessemerized, and thus partly converted into silicate of peroxide of iron, the sulphide of iron will be entirely oxidized, and the slag consequently will contain no sulphur. The oxidation of  $\text{FeO}$  to  $\text{Fe}_2\text{O}_3$  would produce the heat necessary to maintain the slag molten during this operation.

It is probable that the form of furnace eventually adopted will be a modification of the ordinary blast-furnace, fitted with a tuyere hearth. Such a furnace, built on pillars, with bosh and hearth of some substance not rapidly acted upon by the slag formed during the burning of the sulphides would, working continuously, treat a large quantity of material. Being built on pillars, the crucible hearth and tuyere bottom could be replaced when necessary with-

out disturbing the remainder of the structure, and as these would be the only parts in contact with the fused materials, the furnace from the bosh upward should not experience much wear and tear. When a gannister lining similar to the ordinary bessemer lining is employed for the bosh and hearth, the corrosive action of the  $\text{FeO}$  would be neutralized and avoided by introducing with the pyrite sufficient silicious material to produce a slag containing at least as large a proportion of silica as compared with the bases, as the formula  $2\text{RO} \cdot \text{SiO}_2$ . If, however, a basic lining is employed, the slag should contain less silica, and in no case more than the proportion equivalent to the formula  $2\text{RO} \cdot \text{SiO}_2$ . Under such circumstances the blowing would be continuous, the hot charge coming down to a fusion zone, the height of which over the tuyeres would be determined by the amount of air blown in, and the frequency with which the blown products are withdrawn, varying likewise with the composition of the charge. The products could be withdrawn by tapping, as with a common blast-furnace, the matte being run off from a reservoir below the tuyeres, where it would collect. Being thus unacted upon and undisturbed by the blast, rich matte, or even metallic copper,

20-FT. UPRIGHT CONVERTER, GREAT FALLS SMELTER.

could be produced. By continuing the oxidation and producing  $\text{Cu}_2\text{S}$ , and some metallic copper, the gold and silver would be found with the metallic copper. It is well known that small quantities of silver and gold are far more completely extracted from minerals which contain them by smelting, or treatment with fluid metal or metallic matte, than by any wet process. The fact that by such methods practically the whole of these metals present are collected and concentrated, is the fundamental principle of the analytical assay, and is proved by the accuracy of determinations made in this manner. A large side flue, at the top of the furnace, would carry off the gases and sublimes after their temperature had been reduced in heating the charge introduced above through a self-closing hopper. It is calculated that such a furnace, 30 or 40 ft. high, with a hearth capacity of 1 cubic metre, would be capable of treating annually 50,000 tons of pyrite, and a similar quantity of silicious flux, working 200 days in the year.

The theory of smelting sulphides with a blast-furnace is as follows: The operation is started by placing the tuyere hearth in its place, and throwing in hot coke at the top of the furnace. The blast is now turned on, and the coke develops a high temperature by its rapid combustion. The ordinary working charge of sulphide and flux is now introduced at the top hopper, and as the sulphides melt the coke burns away. As soon as a layer of molten sulphide lies over the tuyeres, the blast is increased and also the burden of the furnace. The charge above the fusion zone as it descends is gradually heated, losing much of its sulphur by volatilization before it becomes molten. On fusion, a considerable amount of lead sulphide will distill over, accompanied by the remainder of the arsenic as sulphide in the strong current of nitrogen and sulphurous acid. These gases, as they pass upward in the furnace, will be greatly reduced in temperature by the volatilization of the sulphur and moisture from the crude materials.

There is some reason to believe that more than half of the sulphur in pyrite is volatilized in the free state by this operation. The sublimed oxides, sulphides, and sulphur would be collected in the wide chambers with which the side flue is connected. Below in the hearth the oxygen of the air forced in acts upon the sulphides of iron and zinc contained in the charge, and as long as a constant supply of these substances arrives at the hearth no other constituents present will be appreciably oxidized. A tap-hole near the top of the hearth allows the slag to be withdrawn. The blowing would be continuous day and night so long as the tuyere hearth lasted, and the heat from the gases after they leave such a furnace could be utilized so as to heat the blast or to produce steam-power for the blowing engines. The product of about six tons of material would be tapped every half-hour, so that in seven days' work 1000 tons of sulphide would be treated. If desired, the products could be run direct into suitable reverberatory furnaces, when, after the matte had settled, the slag could be run off while yet in a molten state, and in which the oxidation of the matte could be completed. It is difficult to see how the charge could be overblown, but if it were, the product could be worked up again by adding it to a subsequent charge of sulphides introduced at the top.

The  $\text{SO}_2$  evolved could be oxidized into sulphuric acid in chambers, or reduced to sulphur by  $\text{H}_2\text{S}$ . The latter decomposition might be accomplished by driving superheated steam into the furnace, where the sulphides are oxidized. The  $\text{SO}_2$  could also be utilized by Hargreaves' process, and there are other possible methods of treatment, such as dissolving it in water by spray jets in towers, or by condensing the gas to the liquid state. I am indebted to A. H. Allen for indicating to me a means by which large quantities of liquid anhydrous  $\text{SO}_2$  can be produced, from which sulphuric acid free from arsenic could be made. This plan appears to me simple, and offers many advantages. "The gases, freed from impurities mechanically carried over with them, are first cooled and then led into towers, or other suitable vessels, filled with charcoal, which will absorb and retain the  $\text{SO}_2$  and allow the nitrogen to escape. The  $\text{SO}_2$  is afterward obtained from the absorbent by exhaustion or heat, and, being thus practically free from the nitrogen, can more readily be liquefied by compression than is possible in the presence of a large quantity of that gas. The  $\text{SO}_2$  having been extracted, the charcoal will be ready for another operation, and may thus be used many times in succession."

I have thus endeavored either to prove by experimental data, or to logically demonstrate:\*

1. That the whole of the oxygen of the air driven into a thin stratum of protosulphide of iron ( $\text{FeS}$ ), is utilized for oxidation.

2. That by the heat evolved in the rapid oxidation of sulphides and without the use of extraneous fuel other than that employed in producing the blast:

- (a) About one-half of the sulphur contained in iron pyrite ( $\text{FeS}_2$ ), is expelled in the free state.
- (b) The remainder of the sulphur, excepting that left with the matte, is principally evolved as  $\text{SO}_2$ .
- (c) Although only about 20% of sulphur is oxidized, the proportion of  $\text{SO}_2$  to nitrogen by the new process is 14.9%, which is a larger proportion of  $\text{SO}_2$  than is obtained by copper smelters who manufacture sulphuric acid. In the ordinary method of burning pyrite, where 45% of sulphur is oxidized, the ratio of  $\text{SO}_2$  to nitrogen is only 16 per cent.
- (d) The volatile metallic sulphides, such as arsenic sulphide and lead sulphide, are distilled off with sulphur.
- (e) Iron being more oxidizable than copper, silver, gold, nickel, and certain other metals, these latter will be all concentrated in the matte, provided an excess of sulphide of iron is always present.
- (f) The  $\text{FeO}$  thus formed is converted into slag by the addition of the silica introduced with the pyrite.

- (g) The more perfect fusion of the slag thus obtained prevents loss of copper by entanglement with imperfectly fused material.
- (h) About 16 to 20 cwt. of incombustible material, having a specific heat of 0.15 to 0.25, can be added per ton of pyrite when a cold blast is employed, assuming that  $1000^\circ\text{C}$ . is the temperature necessary for the operation.
- (i) The quantity of similar incombustible material can be increased to 30 to 34 cwt. to each ton of pyrite operated on, when a hot blast of  $500^\circ\text{C}$ . is employed, assuming that  $1000^\circ\text{C}$ . is the temperature necessary for the operation.
- (j) Such incombustible material may contain larger or smaller quantities of valuable metals as oxides which will pass into the matte or be volatilized as sulphides, after double decomposition with  $\text{FeS}$  present in the molten bath. Thus silicates of nickel or copper would be converted into sulphide of nickel or copper, and be concentrated in the matte.

3. That when employing a silicious lining for the furnace the corrosive action of the  $\text{FeO}$  formed is greatly mitigated, if not practically avoided, by the addition of sufficient silica with the charge of pyrite to produce a slag containing more silica than is required by the formula  $2(\text{MO})\text{SiO}_2$  (M representing an atom of divalent metal).

4. That the quantity of coal necessary to produce the blast, calculated on the oxygen requisite for the oxidation which takes place, is  $1\frac{1}{2}$  cwt. per ton of pyrite.

5. That to heat the blast to  $500^\circ\text{C}$ . an additional amount of less than 1 cwt. of coal per ton of pyrite is sufficient.

6. That the new process would materially avoid the destruction of vegetation now so bitterly complained of in Spain, and, at the same time, would greatly increase the profits of the pyrite companies that now employ the cementation process.

7. That the new process could be advantageously employed by the copper smelters for treating rich copper ores on account of the great economy there would be in labor and fuel.

8. That the cost of plant is small, compared not only with the quantity of material it would treat, but also on account of the additional profits derivable from the new process.

## New South Wales Mineral Output

The production of minerals last year proved highly satisfactory, the output having been exceeded only in 1907. The value of the mineral output was \$47,423,909, an increase of \$4,872,821 over 1910. Coal, silver-lead, and copper mines were the principal factors in the increase. The value of the product of the silver-lead mines, including zinc concentrate, was \$19,770,000, an increase of \$3,245,150 over 1910. Underground work in the Broken Hill Proprietary was resumed in February 1912, after suspension for the whole of the previous year. A large orebody was found in the British mine. An indication of the progress made in the recovery of the zinc content from the accumulated heaps of tailing and from the ore hoisted is given by the fact that the export of zinc concentrate for the year totaled 516,378 tons, valued at \$6,876,803, exceeding in value that for 1910 by \$609,182. The output of copper was valued at \$2,871,731, an increase of \$505,371 over 1910. The output from Cobar, which is the chief centre of the copper-mining industry, shows a substantial increase. Tin and tin ore produced amounted to \$1,491,449, an increase of \$384,128 over 1910.

MANGANESE ore amounting to 162,272 tons, valued at \$758,017, was exported from India between April and July of the current year, which is a large decrease from 236,056 tons, valued at \$1,123,730, for the same period of 1911. The exports to the United States were 47,179 tons, worth \$186,465, as against 32,424 tons, worth \$140,870, during the periods stated.

\*Much of the experimental data given in the original paper has, from considerations of space, been omitted.

## The Bishop Creek Mill

By ALGERNON DEL MAR

The Bishop Creek mine, or Wilshire's Bishop Creek mine, as it is more commonly designated, is in Inyo county, California, about eighteen miles from Bishop, on the headwaters of Bishop creek, at an elevation of 8400 ft. As this description is of the mill, the mine only requires passing mention as having been developed to such a stage that it was considered the conditions justified the erection of a unit of ten stamps, with provision for the addition of another unit of ten stamps with only the expense of the extra machinery. Not every one recognizes

The mill, as mentioned, is about 110 ft. above a flat. A road was built connecting this flat with the main road. The problem then was how to land all the material on this hillside without carrying it up by hand, for it was out of the question to try to build a wagon-road to the millsite. This was solved by constructing an inclined track from the flat to the millsite. For power, an engine formerly used on a Sullivan diamond-drill was employed, using air from the compressor.

The surface of the ground when the mortar-block excavation was started was covered with loose boulders. The retaining wall for the ore-bin was built of rock, and will later be faced with two feet of concrete. When bedrock was reached a water Leyner drill was used to smooth it. The illustration shows the main portion of the gyratory

that the critical point in the history of a mine is when the mill is erected. It may be put up before there is sufficient ore developed in the mine to justify the expense, or it may be put up when the company is short of funds. In either case, no matter how good the mine, the result is a failure.

The mountain-side at the mine shaft is precipitous and subject to snowslides. This is the sufficient reason why the mill was placed 700 ft. from the mine, at the only point in the canyon near the mine that is not subject to slides of rock or snow. The mill is 50 ft. higher than the mine shaft. As it required a tramway to transport the ore 700 ft., an elevation of 50 ft. makes little difference in the amount of power required to transport the ore, the 50-ft. rise only requiring 3 hp. This elevation enabled the mill to be placed on solid granite bedrock, with a fall of 110 ft. from the ore-bin to a flat near the creek bottom, thus insuring a gravity system in the handling of the ore. Granite bedrock is not a necessity for light-weight stamps, but for stamps weighing 1250 lb. or over the foundation is of prime importance.

crusher being hauled up the incline on greased tracks. The upper right-hand illustration shows the ore-bin retaining wall faced with concrete and the starting of the ore-bin foundations. The left-hand illustration shows the concrete mortar block for the ten stamps, each weighing 1250 lb. This is the form of mortar block used at the City Deep mill in South Africa. The mixture used in making the concrete was 1:3:3. The battery posts, 12 by 24 in., are held down with cast iron shoes. The hold-down bolts for the post are replaceable. I believe a post 12 by 30 would have been better for this weight of stamp. The back-knee sills are 12 by 16-in. lodge-pole pine; in fact, all the woodwork of the mill is made of this same wood, native to the country, hewn or hauled to the company's sawmill and there cut as required. The ore-bin timbers are all 12 by 12 in., making a solid substantial foundation for the aerial tramway which enters the top of the mill.

The designers of the mill planned to put the crusher, weighing nearly 12 tons, on top of the ore-bin, the tramway dumping directly into the crusher. This appeared to me to be a poor plan. The mine ore being wet, the fine

would clog, and, secondly, putting the crusher on the ore-bin, above this a grizzly, and then the tramway, would make a very high building with a small base and would require excessive timbering to insure stability. The plan I adopted was to place the crusher on a level with and behind the ore-bin, with a separate bin for the coarse rock and an elevator at the crusher to put the ore at any place in the ore-bin that may be required. The tramway then is immediately on the solid ore-bin, dumping on a grizzly, the fine ore going to the stamps and the coarse ore to the crusher ore-bin. In the construction of the ore-bin provision was made for at least two feet of ore to always remain on the inclined surface of the bin. This protects the flooring and stores a small quantity of ore as a reserve that can be easily shoveled down the incline. The stamps are fitted with Pacific guides, these being, in my opinion, the type that requires the least repairs. The ore-feeders are the Traylor make of Challenge feeder with cam grip feed. The mortars are the high back, narrow discharge, El Oro type, weighing about 9000 pounds.

## Copper Production of California

By B. S. BUTLER

\*California was among the earliest of the Western states to make an important output of copper. Production began in the 'Foothill' belt about 1862 and for several years was an important industry, California being second only to Michigan in its copper production. In a few years, however, the industry declined, and California did not take important rank as a copper producer until 1897, when production from the Shasta county district began. Since that time there has been a steady and important output from the state. The production for the early years has been ascertained from the best sources available, and adding to this the known production since 1882, it is found that to the close of 1911 California has produced about 480,970,000 lb. of copper, or 2.90% of the output of the country since 1845. In 1911 the output was 3.27% of the total production of the United States. In total output the state ranks fifth among the copper producers, and for 1911 it ranked sixth. Five plants in the state treated copper ores in 1911, though several of these were operated for only a short period. The main production has come from two districts, though numerous other districts have made small outputs, and copper minerals are widely distributed over the state. The largest producer has been the Shasta county district, and the next most important the 'Foothill' district. In 1911 California produced 35,853,651 lb. of blister copper, as compared with 45,760,200 lb. in 1910. The reduction in output for the state was due to the necessity for eliminating from the smelter fume the constituents injurious to vegetation. This resulted in the shutting down of all but one of the smelters in the Shasta county district.

### SHASTA DISTRICT

The Shasta county copper belt is in the Klamath mountains, at the head of the Sacramento valley, a few miles north of the town of Redding. Sacramento river crosses the belt, separating it into an eastern portion containing the Bully Hill and the Afterthought districts; and a western portion containing the Iron Mountain and the Little Backbone districts. Placer mining was carried on in the district in the early days of mining in the state, and later considerable silver was produced from the gossan outcrop of the copper deposits. Although copper minerals have been long known from the district, it was not until 1897, when the Mountain Copper Co. (Ltd.), began production at Iron Mountain, that it became an important contributor of copper. In 1911 the district produced about 29,900,000 lb. of copper, as compared with about 36,000,000 lb. in 1910. The total production to the close of 1911 has been about 365,900,000 lb.

\*From an advance chapter of 'Mineral Resources of the United States for 1911.'

or about 2.23% of the total output of the country. In 1911 the district produced about 2.72% of the total output. In total output the district ranks eighth, and in production for 1911 it ranked ninth among the copper districts of the country.

The enclosing rock<sup>1</sup> of most of the orebodies is an alkali-porphry intrusive of Mesozoic age. The ore minerals have replaced this rock along zones of shearing. In the western district the ores thus far developed are large, flat lying, more or less tabular bodies of no great vertical extent. In the eastern district they have more the character of veins and, locally, form deposits in the adjoining sediments. The ore in the western district is pyrite, with a small percentage of chalcopyrite and varying amounts of sphalerite. In the eastern district sphalerite becomes one of the important constituents. Rich secondary sulphide ores were found underlying the gossan at Iron Mountain and Bully Hill, but these have been exhausted. The ores carry precious metals, those of the eastern district being rich in them. The average metal content of the copper ores from the district for 1911 was 3.7% of copper, with \$1.80 per ton precious metals.

The producing companies in 1911 were the Mountain Copper, the Balaklala, and the Mammoth. All of the ore is smelted in the same district, except that of the Mountain Copper Co., which during 1911 was treated at its Martinez plant on San Francisco bay. In addition to local ores the smelters treated a variety of ores from Nevada, Idaho, and Oregon, and ore and matte from other districts of the state. A large tonnage of the low-grade gold quartz ores of the districts was used by the smelters to flux their ores. Pyritic smelting is practised successfully in the district. Two smelters were operated in the district in 1911. The Mammoth smelter at Kennett operated throughout the year. It is reported that the bag-house has proved effective in eliminating the injurious substances from the smelter fume, and it is expected that a considerable revenue will eventually result from the materials collected in the bag-house, though a satisfactory process for the treatment of these materials has not yet been developed.

It is reported that the tonnage of ore developed nearly equaled that extracted. The extraction was 270,331 tons. The grade of the newly developed ore is reported as somewhat higher than the average of the old reserves. A new haulage adit, known as No. 5, has been driven 105 ft. below the No. 3 haulage adit. The adit is of sufficient size for the operation of 26-ton electric locomotives and the ordinary narrow-gauge railway cars. The Balaklala smelter at Coram was closed in July by order of the Federal court, on the ground that the fume was injuring vegetation. During the first half of 1911 the company produced 5,026,344 lb. copper, 177,821 oz. silver, and 4005 oz. gold.

The ores of the Mountain Copper Co. were treated at the Martinez plant on San Francisco bay. The company reports the following ore reserves: Iron Mountain mine, 27,979 tons; Iron Mountain mine (in store at Keswick) 37,341 tons—the whole estimated as carrying 3.75% of copper; No. 8 mine, 220,000 tons, of an average content of 4.45%. In addition to this there is the large body of ore developed in the Hornet mine which is low grade in copper, but salable for its high sulphur content. The Bully Hill and Afterthought districts made no production during 1911. The smelter at Bully Hill was closed in 1910 on account of smelter fume difficulties. Electric power is used almost exclusively at both mines and smelters. The district is served by the Southern Pacific railroad, short branches extending to the smelters. The Iron Mountain district is connected with the main line by a narrow-gauge railroad operated by the Mountain Copper Co., and the mines of the Mammoth company are connected with the smelter by a

<sup>1</sup>Diller, J. S., Redding folio (No. 138), Geol. Atlas U. S., U. S. Geol. Survey, 1906; Bull. U. S. Geol. Survey No. 213, 1903, pp. 123-132; Bull. U. S. Geol. Survey No. 225, 1904, pp. 169-179. Graton, L. C., 'The Occurrence of Copper in Shasta County, Cal.,' Bull. U. S. Geol. Survey No. 430, 1910, p. 71.

combined electric railroad, gravity tram, and steam railroad. The ores of the Balaklala mine are delivered to the smelter over a cable tramway.

#### FOOTHILL DISTRICT

The Foothill belt is a rather extensive area of copper deposits which has its best development in Calaveras county. This belt furnished practically the entire copper production from California in the sixties. Following that period of activity, the district was inactive for many years. From 1887 to 1892 the mines made some production. The present period of activity began about 1901, and for some years the district has made important contributions to the copper output of the state. There is no accurate record of the output of this district in the early days, but from the records of the production of the state it is estimated that to the close of 1911 it has yielded approximately 109,500,000 lb. of copper. The production for 1911 was approximately 5,500,000 lb. In total output the district ranks eleventh, and in production for 1911 fourteenth among the copper districts of the country. The ores,<sup>2</sup> consisting of pyrite and chalcopyrite, occur as lenticular bodies replacing schist. The ores

PART OF PENN MINING CO. SMELTER.

vary in different parts of the district from those carrying nearly pure pyrite and chalcopyrite with very low gold and silver content to ores carrying considerable lead, zinc, and precious metal. The ores treated in the district during 1911 averaged about 4.7% copper, with about 2c. in precious metal per pound of copper. The matte smelter of the Penn Chemical Co. was operated in the district, and ore was shipped to custom smelters.

### Queensland Gold Output

The yield of gold in Queensland for August 1912 was 29,976 oz. fine, of the value of £127,330, this being a decrease, when compared with the output for August of last year, of 3210 oz. in quantity and £13,635 in value. The falling off is attributable to the decline in the yields from Charters Towers and Gympie, the decrease amounting to 2700 on the former and 2600 on the latter field. Against these decreases there were improvements at the Etheridge of 263 oz.; at Mount Morgan, of 1704 oz.; at Ravenswood, of 446 oz.; while Cloncurry recorded 1326 oz. as against nothing for the corresponding month of last year. At Croydon, there was a decrease of a little over 400 oz.; while on the Rockhampton fields there was a slight increase. The dividends from gold-mining companies for the month totaled £6086. For the eight expired months of this year the output of gold has been 231,420 oz., of the value of £983,009, this being a decrease, when compared with the corresponding period of last year, of 18,053 oz., and £76,684, respectively.

## The Colorado Mine and Mill, Philippine Islands

By PAUL R. FANNING

\*During the first part of 1911 the Colorado Mining Co. continued development to prepare the mine for the 20-stamp cyanide mill which was nearing completion. During 1911 the mill operated irregularly for less than two months, but steady production did not begin until the last of December.

*The Mine.*—An accurate description of the mine and ore-

COLORADO MILL DURING CONSTRUCTION.

bodies has already been given by Eddingfield. The vein averages 4 metres in width, strikes south 45° east, and dips 70° to the northeast. The vein matter consists of quartz, with some calcite and manganese. The ore is stated to average ₱20 per ton.

The inclined shaft now reaches a depth of 146 metres, which is the greatest depth penetrated in the district, perhaps in the Philippine Islands. As stated by the company, the average precious-metal content shows only a nominal decrease from the top to the bottom of the shaft, and the bottom ore is said to have a value of more than ₱16 per ton. It is to be noted that this ore is still above the level of the permanent ground-water, and hence in the oxidized zone. The indications are that the zone of oxidation should extend to a depth approximately equal to the level of the Guinobatan river; that is, 100 metres below the present bottom of the shaft. It is probable that good ore will be found to this depth, and it is possible that the zone

\*Extract from 'Mineral Resources of the Philippine Islands for 1911.' The peso is the Philippine peso, of a value of \$0.50 gold.

of oxidation may extend to an even greater depth. Whether or not a zone of enriched ore will be found at this depth is too problematic for present consideration, although the presence of manganese in the ore, as has been repeatedly pointed out, is highly suggestive of a zone of richer ore close to the level of the permanent ground-water.

The mine has been developed by means of two main adits, 53 metres apart vertically; the upper, or No. 1 adit, is 30 metres below the highest point in the outcrop. Two intermediate levels have been run, and various cross-cuts and raises put in. During 1911 a drift was run next to the hanging wall parallel to and connecting with No. 1; the main, or No. 2, adit was continued 80 metres farther to the northwest; the upper intermediate level was run for a distance of 120 metres; the lower intermediate level was run for a distance of 180 metres; and the shaft was sunk 30 metres to a total depth of 146 metres. In all, some 800 metres of work was performed, besides preparing the ore-bodies for stoping.

In stoping the ore the square-set system of mining has been used, but owing to the high cost of timbering it is probable that some modification of the method will be adopted. The mine is surrounded by a forest of magnificent hardwood trees, but the cost of cutting, transportation, and dressing is very high. The tangle of underbrush and vines require an extra amount of work to fell the trees after cutting, and the wood is so hard that the natives saw it with difficulty. The sets are framed by hand and are so heavy as to require several men to handle each piece. The substitution of dressed pine shipped from the United States for native timbers is being considered as an economical measure.

**The Mill.**—The 20-stamp cyanide mill is of Traylor design and is of the all-sliming type, crushing in cyanide solution. The striking feature of the practice is that the gold solutions from the Dorr thickeners pass to the zinc-boxes without filtering in the Oliver filters. The ore is delivered from the second level of the mine to the storage bins, and thence to the mill by means of a 2-bucket aerial rope tramway 320 metres long.

**Crushing.**—The ore from the buckets passes to a 3 by 8-ft. grizzly; the oversize is crushed in a 10 by 20-in. Blake crusher and passes to the bin. The ore is fed into four 5-stamp batteries by Challenge feeders. Lime, which is prepared in a kiln near the mine from a local deposit of calcite ore, is added at the batteries. The 20 stamps, weighing 1250 lb. each, drop at the rate of 109 per minute; the height of drop is about 8 in., and a 4-in. discharge is used. The ore is crushed in solution of a strength varying from 0.12 to 0.20% potassium cyanide. A capacity of 4.5 tons per stamp per 24 hours is obtained when a 6-mesh screen is used. The pulp, which has a thickness of about 6 parts of solution to 1 of ore, passes to a Dorr classifier, where the sand is raked out and delivered to two 5 by 18-ft. tubemills. These mills are of Traylor manufacture, with trunion bearings and spiral feed. A speed of 28 r.p.m. is used. The lining is of the El Oro type. At first, Danish pebbles were used entirely, but at present some of the harder quartz from the mine is added. The discharged pulp, which contains about 40% moisture, passes to a bucket elevator and is returned to the Dorr classifier.

**Treatment of the Slime.**—The slime, having a thickness of about 9 to 1, passes from the Dorr classifier to a 20 by 14-ft. Dorr thickener. The overflow from the thickener passes to a clarifying tank, thence to a gold-solution tank, and thence to the 7-compartment zinc-boxes.

The pulp from the thickener passes to two 12 by 40-ft. Pachuca tanks, connected in series. The central columns of the Pachuca discharge at the surface and an air pressure of about 32 lb. is used. The solution has a strength of from 0.12 to 0.20% potassium cyanide, and the pulp has a thickness of about 1.5 to 1. After agitation in the Pachuca, the pulp passes by launder to a second Dorr thickener. Previous to entering the thickener the pulp is diluted with solution from the Oliver filters. The overflow from the thickener passes to a clarifying box, and thence

to two sets of the 7-compartment zinc-boxes. When first operated the thickeners gave trouble owing to the great amount of slimy foam which overflowed with the gold solution. This difficulty was overcome by removing alternate bolts on the rim launder and drawing off the solution just below the surface free from foam. The foam is drawn off separately by a central launder and passes to the Traylor agitator.

The pulp from the thickener passes to a 20 by 8-ft. Traylor agitator, which prepares the pulp for two 11 by 6 by 8-ft. Oliver filters. From the filters the gold solution passes by means of wet and dry vacuum pumps to a 12 by 10-ft. storage tank. From this part of the solution is pumped to dilute the pulp entering the second Dorr thickener, and the remainder is pumped to the 28 by 14-ft. solution storage tank at the top of the mill. None of the solution from the filters passes directly to the zinc-boxes.

**Solution of the Gold.**—As noted, a feature of the practice is that the gold solution is taken from the Dorr thickeners for precipitation rather than from the Oliver filters. The reason for this lies in the fact that about 80% of the gold goes into solution before the pulp reaches the Pachuca. It would seem from this that the greater part of the gold is very fine, easily liberated, and readily attacked by the cyanide solution. The presence of manganese probably has been instrumental in producing this condition of the gold. Some coarse gold and gold bound up in the minerals are present, and the Pachuca give the added time necessary to their dissolution.

**Precipitation and Clean-up.**—A general clean-up is made every two weeks, and the bullion is melted once a month. The zinc fine is treated with sulphuric acid, and the gold slime is washed, steam-dried, and melted in a gasoline tilting crucible furnace. The bullion is shipped to Manila, where the International Banking Corporation advances a sum based on the company's own assay. The bank ships the bullion to San Francisco, and later makes adjustments with the company.

**Cost of Operations.**—The cost of mining and milling at the Colorado mine has been placed at less than ₱8 per ton, and there is some reason to believe that this figure will be reduced under conditions of steady operation. The fact that the cost of mining is moderately low would lead to the belief that, considering his low salary, the Filipino is an efficient miner. It is to be remembered, however, that the vein is of such width as to permit stoping on an economical scale. Furthermore, most of the ore is sufficiently soft and fractured as to be readily mined without the use of dynamite. On the other hand, the cost of general supplies is high, although lower than at many mines in the United States not situated directly on a railroad. The anomalous condition of having a timber problem in the midst of a great forest has already been discussed, and this problem will become more acute as the trees are removed and it becomes necessary to bring timber from a distance.

Owing to the excessive cost of the mill, the original investment is large in comparison with the capacity, and this means a higher cost per ton than usual, owing to the factors of depreciation and interest. For this mill these two factors alone mean a cost of about ₱1 per ton, and it is possible that this amount has not been included in computing the total cost of operation.

It was my belief when first coming to the Philippines that the depreciation for this country would be especially high, and experience in many cases has justified this belief. However, there are instances where, under good construction, the depreciation has been no greater than in the United States. The destruction of buildings under the attacks of white ants or other insects does not always seem a serious consideration, as there are numerous buildings, properly constructed, which have lasted for many years; certainly many years longer than the probable life of any mine. It is also known that white ants do not attack timbers which vibrate under the shocks of machinery. The construction work on the Colorado mill is of such order that it appears unnecessary to allow an excessive depreciation charge.

## Work of the Cananea Copper Company

By L. D. RICKETTS

\*The physical condition of our mines is good. I look for a satisfactory year ahead and a notable increase in the output of both copper and silver. The important developments of new ore have all been in the limestone areas. These ores contain from 3 to 5% copper and from 1 to 4 oz. of silver, and from 10 to 30c. in gold per ton. They are direct smelting ores, highly basic in character. As intimated in my last report, no attempt was made to press production during the year, but, on the contrary, curtailed production was aimed at. On account of the development of basic high sulphur ores, there was need, however, of more silica, and operations consequently were resumed at the Henrietta mine, which was closed down in 1910, and the Cobre Grande mine was also reopened. Toward the

Combination adit, at the close of the year, was 5200 ft. from the portal, and is being slowly driven ahead. The adit has passed entirely beyond the Elisa zone and has entered the Cananea claim.

The Elisa mine has continued to improve through development in the past year. The main ore-shoot has been opened on the sixth level and has been cross-cut by extraction adits on the level of the Combination adit, and the main shaft will be sunk during the coming year to develop the ore below. The ore has been of a satisfactory grade, and the mine is looking better than it has at any time during the past several years.

Possibly the most encouraging developments on the entire property have been in the limestone area of the Sierra

SMELTING PLANT OF THE GREENE-CANANEA COPPER COMPANY.

end of the year work was also started at Puertecitos with a view to increasing output when necessary.

At Puertecitos a new quarry for oxidized ores has been started, and J. H. Kirk has undertaken the development of the porphyry contacts on either flank of the limestone core of this hill. The results of his work are promising, and he expects by the middle of the coming year to obtain over 200 tons of smelting ore per day from this mine. Most of the work done, however, is dead work preparatory to extraction, which accounts for the high costs at this mine.

The Henrietta mine proper, while profitable, is a small mine, and no large orebody has been found in its workings. It is used, however, as a base for broader work, and two long cross-cuts are being driven, connecting with each other for air, that will ultimately attain a length of several thousand feet. They run south, toward the main cordón, and are intended to intercept the mineral belt thought to exist far out in this direction. This work will tend to give information as to the future direction of the Combination adit, which will ultimately serve as an outlet for this district, should it develop as hoped. The face of the Com-

de Cobre mine, over the Combination adit. In my last report I referred to the fact that the Eureka fault, which appears to be the extension of the Capote fault, had large masses of gossan along it and would probably develop important bodies of ore. This prediction has proved correct, and very important orebodies have been developed in the limestone adjacent to this fault at three points, and have cross-cut ore in a number of places in the limestone that will undoubtedly yield important tonnages in stoping. The ore in this area is exceedingly irregular in its occurrence, and a great deal of prospecting is done in stoping.

Developments on the tenth level of the Capote mine under the old orebody have been disappointing, although some ore has been discovered in the old body between the eighth and tenth levels. In the early history of this district, in the year 1899, one of the Capote adits crossed an exceedingly lean body of iron pyrite on the first level. Owing to the similarity of its occurrence to the ore found in the Sierra de Cobre, and owing to the fact that in the Sierra de Cobre nearly barren pyrite is often found, it was decided to develop this zone. We first discovered ore that is undoubtedly connected with it on the ninth level. During the year the ore has been opened on the second, third, fourth, and fifth levels, and there can be no question

\*From a report for the year 1911, made to the board of directors of the Cananea Copper Company.

but that this ore will continue as far as the ninth level. A great deal of the ore is an exceedingly lean iron pyrite containing a high percentage of sulphur, and cannot be handled at the present time, but there are notable quantities of the ore on the lower levels that is of profitable smelting grade. The mass of pyrite on the fifth level is about 220 ft. long, with a maximum width of 100 ft., and the indications are that a large tonnage of profitable ore will be obtained, even if a way of treating the leaner material cannot be found at present. This ore contains a certain amount of silver as well as copper, and as long as it contains over 2½% copper it should be profitable at the smelter. A considerable amount of it will average nearer 4 per cent.

The Oversight mine has maintained a steady production, and much more first-class smelting ore has been developed than was expected. At the same time, this ore has come within the limits of the main ore-zone, and during the year the amount of ore developed has not equaled the amount of ore that has been extracted from the mine. Development in this mine has not been pressed, but during the coming year a further geological study of ore occurrence will be made and development work will be more extensive. It is also intended to develop the old Esperanza orebody, which contains concentrating ore of rather low grade, but which should be profitable under present conditions. The Veta Grande mine will be opened and mining operations resumed during the latter part of the coming year. For the year 1911 it has been idle. The Kirk mine during the year produced about 95,000 tons of ore, most of which was of a smelting grade. There are no new developments of importance in this mine. The Cobre Grande mine has produced a notable quantity of ore for converter lining and for smelting. The old orebody is not adapted to concentration. A new body of concentrating ore has been found to the west. It is of good grade, but apparently not of large extent.

The tendency for the future is toward lower-grade matte, and I am endeavoring to develop ores low in sulphur to help raise the grade of the matte. With this aim in view, a four-fifths interest in the Superior Bonanza mine, situated near Imuris, Sonora, has recently been bought. This mine yields a silicious ore containing small quantities of copper and notable quantities of gold. This class of ore is needed to assist in raising the grade of the matte and to furnish flux for the iron.

The amount of money involved in the purchase of this mine is not large. It is probable that no production will be made from it until some time in 1913, as development is being continued and it is hoped before that time a sufficient tonnage of ore will be developed to justify building a railroad for the 5½ miles between the mine and the Sonora railroad. The railway company has given a reasonable rate on this ore, so that it can be brought to Cananea and smelted at a profit.

Mine.	Total	Stoping	Development	Dead Work and Stoping Expense.	Total
Puertecitos .....	6,505	\$3,373	\$4,561	\$1,976	\$9,910

60% S. de Cobre	81,611	1,446	0,736	0,556	2,738
	715,462	1,311	0,557	0,592	2,460

#### COST OF MINING

The cost of mining for the Cananea Consolidated Copper Co. in 1911 was \$2.46 per ton, as against \$2.75, \$2.22, \$2.13, and \$3.28, for the four previous periods. Considering the fact that the amount of first-class smelting ore, which requires a certain amount of selection and hand sorting, has largely increased, I consider this cost as most satisfactory. The tonnage produced and the segregated costs for mining at the various mines are shown in the foregoing table.

The amount of development work driven totaled 51,784 ft. of which 696 ft. was shafts and 9811 ft. was raises and winzes. The average cost per foot for the completed work was about \$8.

#### THE CONCENTRATORS

The wooden jigs of Mill No. 2, which have been in service for about eight years, have rotted out, owing to the acid character of the water. During the year almost all of these jigs have been replaced by reinforced concrete jigs, the cost of which has been charged to operating expense. Other work has been done in the way of putting in drag classifiers to separate coarse sand from slime and very fine sand without the use of water. Many small improvements have been made, but none of great magnitude.

During the year 528,412 wet tons of ore was milled. Of this, 415,199 wet tons was produced from the company's mines, and 113,213 wet tons was produced from the Cananea Duluth mine. The former had a concentration ratio of 2.40 into 1, and the latter a concentration ratio of 5.17 into 1. The operating and repair cost was \$0.646, and improvements and betterments amounted to \$0.076 per wet ton, giving a total cost for the year of \$0.722. The average saving of the copper in the ore in concentrate was 77.69 per cent.

The new impounding dam for tailing is serving most satisfactorily, and every pound of tailing, whether slime or sand, is being saved, and there can be no question but that the reclamation of clear water from the tailing pond is of more value than the cost of impounding the tailing. The concentrators are in most excellent condition, and in fully as good a state of repair as they have ever been in their history.

#### THE REDUCTION DIVISION

The cost per dry ton of new copper-bearing material treated for the past several years has been as follows:

1907 .....	\$6.82	1910 .....	\$2.69
1908 .....	3.86	1911 .....	2.57
1909 .....	3.09		

The last report predicted that a smelting cost of \$2.25 per ton would be obtained. As will be seen from the above table, this prediction has not been fulfilled so far, the reason being that the average grade of the matte has been much lower than formerly, the converting department was congested, and the amount of by-products to be handled very largely increased. The management is, however, attacking this question, as will be seen later, and has by no means given up hope of attaining the cost predicted.

The reduction works treated 580,060 dry tons of new copper-bearing material. The high cost of converting may be seen from the segregated costs for this division:

	Per dry ton.
Sampling .....	\$0.0222
Bedding .....	0.0584
Reclaiming .....	0.0202
Blast-furnace costs .....	1.4055
Reverberatory costs .....	0.3197
Calcining costs .....	0.0510
Converting costs .....	0.6518
Indirect custom ore costs .....	0.0351
Flux .....	0.0071
Total .....	\$2.5710

The cost of McDougall roasting for the year was 40c. per dry ton, and the gross cost was made up as follows:

Sampling, bedding, and reclaiming.....	\$0.1262
Operating furnaces .....	0.1894
Transportation of calcines .....	0.0228
General expense and flux.....	0.0619
Total .....	\$0.4003

Of the total charge to the reverberatories of 113,782 dry tons, 41,883 tons was flue-dust, 66,299 tons was calceine, and the remainder was silicious ore and flux, the latter amounting to but 1194 tons. The average weight of the calceine produced from a ton of the concentrate was 1675 pounds.

The second reverberatory furnace was completed and put in operation early in the year. The old furnace was then torn down and rebuilt. Twelve-inch buckstays were used in place of the old 8-in. buckstays, and a 20-in. arch was employed in place of the previous 12-in. arch. New castings were furnished for the furnace, and the flue leading to the boilers was enlarged. This entire cost, amounting to \$0.223 per ton of material smelted, was charged to operation. The cost of smelting a ton of charge was \$1.65, as against \$1.90 for the previous year.

Without the cost of rebuilding the No. 1 furnace, which with ordinary repairs will last for many years, the cost was \$1.427 per ton of charge. These figures are shown as follows:

Labor, operating .....	\$0.2982
Labor, repair .....	0.1547
Shop expense .....	0.0151
Supplies and material.....	0.2070
Power .....	0.0095
Fuel oil .....	1.4882
Flux, cost of .....	0.0223
Sundry .....	0.0566
	\$2.2516
Steam credit .....	0.8245
	\$1.4271
Rebuilding No. 1 furnace and flue.....	0.2232
Total costs .....	\$1.6503

During the year basic lining has been employed in our barrel type shells, but investigation has demonstrated that these shells are not as well adapted to economical work as the Great Falls type of converter. Two stands of converters of the Great Falls type have accordingly been ordered, together with additional blowing engines, and shortly after the middle of the coming year the converting capacity will be increased until it will be capable of producing a total of eight to nine million pounds of copper when necessary. At the same time it has been decided to increase the blowing capacity for the blast-furnaces, for the reason that the sulphur content of the newly developed ores requires more oxygen for smelting.

THE POWER-HOUSE

Heavy expense has been incurred at the power-house during the year, but, notwithstanding, the cost of power has shown a satisfactory decrease. The cost per indicated horse-power for the year has been \$5.568, as against \$6.54 for the previous year. This cost should be gradually decreased when the contemplated additions to the power-house are finished.

MINING AND REDUCTION

The copper costs for the past year were as follows:

	Per lb. of copper.
Gross costs, f.o.b. Cananea.....	\$0.09568
Freight to New York, refining, marketing, etc....	0.01343
Total costs .....	\$0.10911

Credit:

Value of precious metals.....	\$0.01339
Miscellaneous revenues .....	0.00484
Total credits .....	0.01823
Total cost, fine copper sold.....	\$0.09088
Construction .....	0.00755
	\$0.09843

The total cost of mining and treating a ton of ore, including every cost until the refined copper has been sold, has been as follows:

	Per ton.	Tons treated.
Fiscal year 1905-1906 .....	\$10.210	947,977
August 1, 1906, to October 31, 1907..	7.625	1,305,291
July 11 to December 31, 1908.....	5.976	295,554
Fiscal year 1909 .....	5.459	835,929
Fiscal year 1910.....	5.765	792,856
Fiscal year 1911.....	5.257	741,873

These costs are exactly comparable, and for the year 1911 the figure of \$5.257 includes an item of \$0.377 to cover construction as well as every item of repairs and replacements, which were quite extensive. The actual yield per ton of ore treated was 50.01 lb., as against 46.58 lb. and 44.12 lb. for the two preceding years. It is probable that during the coming year the yield will not be so high, for the reason that certain bodies of very lean concentrating ore have been found that can be mined very cheaply, and with the high price of copper it will be profitable to mine this ore at the expense of a drop in the yield per ton, but the cost per ton for mining and beneficiating should also drop. The total amount of money spent for betterments and improvements and extraordinary repairs was about \$435,000, of which, in round numbers, \$280,000 was charged to construction and the balance against operating costs. Aside from the improvements to the power-house and the converter department, the construction to be done during the coming year is not so heavy.

TONNAGES

	Wet tons.
Domestic ore mined.....	751,462

RECOVERY FROM ORES

Recovery from domestic ores treated was as follows: .  
Copper...2.5%      Silver...1.0718 oz.      Gold...0.005 oz.

## Concrete Shaft-Lining

By F. E. CALKINS

The reinforced concrete lining of the 2-compartment Kingdon shaft at the United Globe mine of the Old Dominion company at Globe, Arizona, was completed on August 28, the lining extending from the collar to the bottom of the shaft, a distance of 1017 ft. In October 1911 the timbering of this shaft was destroyed by fire, and it was decided to put in a concrete lining. The contract was let to Paul Michaelson and C. H. Weideman, construction engineers formerly employed by the Old Dominion company, and preliminary work was started in January 1912. It was decided to build the lining by lifts or sections, beginning near the top and working downward, and the work was finally accomplished in six sections, from 150 to 220 ft. in height, depending on the condition of the ground.

About a month was spent in the preliminary work of erecting a temporary head-frame, crushing plant, concrete mixer, and other machinery, and in cleaning down the charred timbers and loose rock from the first section, extending from the collar to a point 160 ft. below. Two specially built, heavy wooden cages, swinging freely in the shaft, were used throughout the work. In lining a section, the walls were stripped of charred timber and loose rock, beginning at the top and working downward, and light temporary sets of timber were put in, with some lagging wherever necessary, so that the men were always protected from falling ground. When the bottom of the section was reached, temporary timber bearers were placed along the sides and ends and across the centre of the shaft, forms were built upon them, and a permanent reinforced concrete bearer, four or five feet high, was put in. Two or three days were allowed for this to set, after which the concrete lining was built up on top of it. The forms were built in sections 12 ft. high, and the concrete poured in between the form and the rock walls of the shaft. As soon as one 12-ft. section was filled, another was erected on top of it, plumbed and blocked, and filled with concrete in the same manner. The work proceeded thus until the bottom of the finished lining above was reached, the temporary timbering being removed as fast as the forms were erected.

The concrete was made to run from the conical mixer into a hopper and down the shaft through a 4-in. iron pipe to the point where it was needed, where it was caught in an ordinary steel sinking-bucket suspended from the finished portion of the lining above, and allowed to run through a hole cut in the side of the bucket a few inches above the bottom, and through a short steel chute into the forms. This was a very efficient and flexible arrangement, as the bucket could be easily swung or turned, and a continuous stream of concrete directed to any part of the forms desired. The concrete was successfully dropped in this manner for a distance of over 1000 ft. in building the last section.

The long walls of the lining were given a minimum thickness of 10 in., and the short walls and centre wall 8 in. Where the rock walls were very irregular, forming large hollows, large rocks brought down on the cages were thrown into the concrete. The centre wall was reinforced every 18 in. vertically with mine rails laid across the shaft in the centre of the wall. The end and side walls were thus reinforced only at points where the ground was bad and at stations. Bolts were imbedded in the concrete at regular intervals for fastening the guides.

The concrete was a 1:3:6 mixture of portland cement, quartz sand, and crushed limestone from 1/4 to 1-in. size. About 2300 cu. yd. of concrete and 750 cu. yd. of large rock were used. About 25 men were employed on the job, working two shifts. The total time consumed was 8 months, of which the first month was spent in rigging up the surface plant, cleaning down the walls, and put-

ting in temporary timbering preparatory to concreting. Also, the lower 110 ft. of the shaft consisted of a raise driven to one-compartment size, and this had to be enlarged to full size. The actual work of concreting was done in 100 days, or about 40% of the total time consumed. Ordinarily, one 12-ft. section of concrete per day was put in, but in bad ground a 6-ft. form would be used. The maximum day's work was 22 feet.

The two compartments are 5 by 7 ft. 2 in. inside the finished lining, and the shaft will be used only for ventilation and for hoisting and lowering men working in the east end of the mine. It is most interesting to note that the area of the compartments is over 60% greater than the area of the old timbered compartments, which were 4 by 5 1/2 ft., showing that with a given area of ground broken a much larger shaft area may be obtained with a concrete than with a timber lining. The contractors received \$30,000 for their work, or \$28 per foot.

## Cleveland Meeting of the Institute

The 103rd general meeting of the American Institute of Mining Engineers was held at Cleveland, Ohio, on Monday, Tuesday, Wednesday, and Thursday of this week. The meeting was opened on Monday evening at the Statler hotel by an informal social gathering at which two hundred members were in attendance. Technical sessions were held on Tuesday morning and afternoon and on Thursday morning. Nearly fifty technical papers were scheduled for presentation, and these were first grouped for presentation and discussion. The first paper was by R. W. Hunt, on the inspection of steel rails, and was followed by a study of the cleansing effect of titanium on cast iron, by Bradley Stoughton. W. A. Barrows and Carl Zapffe presented a description of the Cuyuna iron range, and were followed by R. R. Abbott with a comparison of the action of various carbonizing materials. Next came a study of the hardening of steel by different methods, presented by M. A. Ammon, followed by a commentary on Ruffs carbon-iron diagram, by H. M. Howe, and a criticism of Wittorff's investigation of the permutations in ferro-alloys containing more than 4% of carbon, by Bradley Stoughton and Simon Marcus, both papers being presented by Mr. Stoughton, in the absence of Mr. Howe. On Tuesday afternoon R. H. Sweetser discussed the blowing in of blast-furnaces, and Elwood Haynes exhibited a remarkable series of alloys of cobalt and chromium which have properties superior to those of steel. W. N. Blauvelt discussed the manufacture of coke, followed by F. E. Lucas and F. W. C. Schniewind upon the same subject. N. V. Hansell described the methods recently introduced in the concentration of iron ores, and J. E. Johnson presented a study of the effect of alumina in blast-furnace slags, that gave rise to general discussion. The meeting on Wednesday was devoted to the discussion of the proposed amendments to the constitution and by-laws of the Institute. The discussion was general, but no final action was taken, and a final draft of the proposed amendments will be presented at the adjourned meeting to be held in New York City on November 12, when it will be put in such form that it can be adopted at the annual meeting in February next. The technical session on Thursday morning was devoted to general Western mining and metallurgy. On Tuesday night the visiting members were entertained at a smoker and on Wednesday evening there was an elaborate subscription banquet for the members and ladies. Excursions to points of interest were made on Tuesday and Wednesday afternoons.

THE TENGO MINING Co., in the Aroroy district, Masbate, Philippine Islands, did a little development work and operated the mill for a few days, during which some ₱2000 worth of gold was recovered by amalgamation alone. It is now fairly well established that the ores of the district require a large outlay of capital before successful work can begin.

Prospecting in Tasmania

LAUNCESTON CORRESPONDENCE

The Tasmania Minister of Mines, Edward Mulcahy, is seeking to cope with the falling off in mineral production that has been pronounced in Tasmania for some years past. In five years the value of the output has declined about 50%, despite the great increase of the prices of metals. This is due to some extent to a deficiency of labor, but mainly to the fact that the value of the ores generally has declined materially. The Minister has come to the conclusion that the only way to remedy this serious state of affairs is to make new discoveries, and for this purpose to expend a sum of \$90,000, quite a considerable amount for the small and not very rich state of Tasmania, on the erection of a public stamp-mill at a cost of \$30,000; on equipping and sending out prospecting parties to explore and report upon likely mineral areas; and on granting assistance to properly equipped private parties operating in favorable areas under approved conditions, conditionally on their undertaking to provide the Department with certain required information. The scheme is a wise one, and may lead to something; but, as has been pointed out, it is not clear what is to happen if any discoveries of value be made. It would be interesting to know if it be Mr. Mulcahy's intention to take up and work on behalf of the state, deposits discovered by Government parties on Crown lands; and if, where the Government has merely granted assistance, it will claim an interest. On these points all is silence and there may never be any call to ascertain the Minister's intention. But, again, there may.

Record Zinc Production

The production of primary spelter (zinc) from domestic ore in 1911 was 271,621 short tons, valued at \$30,964,794, according to a statement just issued by the United States Geological Survey. This is the greatest production in the history of the industry and shows an increase of 19,142 tons over 1910. The imports of spelter, however, reached the lowest figures in recent years, while exports increased about one-half over those for 1910. The great growth of the zinc industry in the United States is indicated by the following figures:

PRODUCTION OF SPELTER IN THE UNITED STATES FROM DOMESTIC AND FOREIGN ORES, 1880-1911		
	Short tons.	
1880 .....	23,239	
1890 .....	63,683	
1900 .....	123,886	
1905 .....	203,849	
1910 .....	269,184	
1911 .....	286,526	

The following table is of interest as showing the principal sources of the domestic zinc production:

PRODUCTION OF ZINC IN THE LEADING STATES IN 1911, IN SHORT TONS		
State.	Recoverable zinc.	Crude zinc and zinc-lead ore.
Colorado .....	47,304	325,230
Kansas .....	10,272	761,465
Missouri .....	122,515	8,162,076
Montana .....	21,905	225,714
New Jersey .....	77,445	375,064
New Mexico .....	5,119	24,735
Oklahoma .....	5,150	224,450
Utah .....	8,920	286,570

At Penang a development syndicate has been formed to exploit tin properties on the border of Siam. The tin ground appears, from reports, to be extraordinarily rich.

A New Type of Mine Air Humidifier

The United States Bureau of Mines has on exhibition at its Pittsburg testing station a machine for producing a water mist that is almost fine enough to be termed a fog. As shown in the illustration, the machine consists of a hollow wheel mounted upon the shaft of an electric motor. The wheel is provided at its periphery with spray nozzles, at its hub with an opening for the admission of water, and on its back with fan blades. The back and rim of the wheel is enclosed in a steel housing that serves as a casting for the fan, as a support for the air-diffusion vanes, and as a shield for the revolving parts. When

the wheel is rotated at normal speed by the motor, and water is admitted (under practically no pressure) to the opening in the hub, centrifugal force develops, at the nozzles in the wheel's periphery, a hydraulic pressure of more than 200 lb. per square inch. This pressure drives the water through the nozzles in the form of a fine spray which is seized, broken up still more, and finally carried away by the blast of air that the fan-blades on the back of the wheel blow out all around the rim of the wheel between it and the surrounding housing. The diffusion vanes cause the air to be discharged in the form of a cylinder whose axis is coincident with the fan shaft. The mist produced is extremely fine, and there is practically no dripping of solid water. The device, which was developed by H. H. Clark, one of the Bureau's engineers, is not yet in its final form, and has not yet been tested in actual practice.

There has been a gradual, if fluctuating, increase in the amount of iron ore, zinc ore, and phosphates mined in Algeria, about \$2,000,000 worth of each of these products having been exported in 1911. It is likely that when the projected railroad to the hitherto undeveloped Ouenza mine has been completed there will be an important increase in the amount of iron ore exported, as the Ouenza mine is believed to be one of the largest bodies of iron ore yet discovered.

During September the Elmore vacuum plant at the Sulitjelma mines, produced 1104 tons of copper concentrate.

## Discussion

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment. Insertion of any contribution is determined by its probable interest to the readers of this journal.

### Cripple Creek History

The Editor:

Sir—In your issue of October 12, you quote from the 'Twenty Years Ago Today' column of the *Colorado Springs Gazette* to the effect that shipments made in 1892 from the Cripple Creek district went out on burros. The *Gazette* is in error. The ore was hauled in wagons, most of it to Florissant and Divide on the Colorado Midland railroad, though some went to Canon City on the Denver & Rio Grande railroad. Burros were never used to pack ore from Cripple Creek, as there were wagon-roads into the district from the very beginning.

Colorado Springs, October 16.

HORACE F. LUNT.

### What Are Mining Profits?

The Editor:

Sir—It is announced by the Treasury Department in Washington that R. E. Cabell, Commissioner of Internal Revenue, will soon make some ruling on how to estimate depreciation in oil land and mining properties so as to arrive at a basis for levying the corporation tax. Mr. Cabell has been traveling through the West, together with L. F. Speer, chief of the corporation tax division, studying this question. In your issue of October 5, J. R. Finlay objects to an editorial criticizing the decision of a Colorado judge that the removal of ore from a 'mine is not depreciation.' While I believe that Mr. Finlay's objection is well taken and agree with most of his contentions it would be interesting to hear the ideas of other engineers, and in this connection the following may interest some of your readers who are not familiar with the subject. The decision in question was that rendered by Judge Polk of the Federal district court at Denver in the case of *Strattons Independence v. F. W. Howbert*, collector of internal revenue. The court held that the value of the ore extracted cannot be charged to depreciation in estimating the net income, which is the subject of the tax levy. The court also decided that the corporation tax is not a tax levied upon the estate proper and is thus without the constitutional prohibition against levying a direct tax not apportioned among the states. The following extract from the court's decision will be of interest with reference to the definition of net income and depreciation to be observed in computing mining income for purposes of taxation.

"In popular sense the net income of mining properties is the value of what is extracted after deducting the cost of extraction and treatment, and the cost of administering the company which may be conducting the operations, and finally after a reasonable reservation for contingencies. This is true not only as a matter of general understanding, but it has been held uniformly by the courts to be a proper rule in determining whether or not a dividend is declarable by such companies.

"The net income of a mining property for the purpose of dividends does not take into account so-called waste of the property by reason of the extraction of ore in place, but that such is to be determined by a comparison of the proceeds of the company, after a deduction for operation, expenses of the company, and such reasonable contingencies as may in the light of experience be expected.

"If, therefore, the net income is not affected for the purposes of dividends by the amount of ore extracted, neither should it be affected by that circumstance for the purpose of an excise tax. We conclude, therefore, that the words 'net income' do not carry with them any contemplation of law that there shall be such a deduction as plaintiffs here claim.

"The ordinary definition of depreciation is the lessening of value. As applied to mining properties, the word carries with it, as in the case of any other business, the idea of deterioration in visible improvements, so far as they are put in by the hand of man, and, therefore, speaking popularly, when we think of depreciation in mining properties we think of a lessening in value by time, or perhaps by accident, of those physical elements which go to develop and to improve the property.

"Now, does this meaning, commonly entertained and accepted and which is common to every class of corporations, become enlarged in case of mining companies, so as to make the extraction of ore likewise an element of depreciation? The court's view is that it does not. This conclusion is in part induced by the reasons which have been above discussed in connection with the term 'net income' and in part by the peculiar nature of the mining business. The latter is *sui generis*. It lives by dying. It is a business that is intrinsically uncertain.

"The taking out of ore, while in a sense depreciation from the body, very often leads to the revealing of still larger bodies, and thus results not in a lessening of the value of the claims, but in a great increase in such value. As applied to this class of corporation, having as its purpose to exhaust—it may be a year hence or a hundred years hence—the body of ore for profit, the mere fact that ore may be extracted does not, in my judgment, make the value of such ore an element to be classed and deducted as a depreciation of the property. The court, therefore, holds that the extraction of ore does not constitute a credit in favor of mining companies upon the account between them and the Government when the excise tax is to be assessed."

In this connection the following extract from the secretary's report of the Goldfield Consolidated, for the year 1911, showing the method employed at that property for figuring 'depreciation' for tax purposes, may be of interest.

"Under the act of Congress approved August 5, 1909, and popularly known as the Federal corporation income tax law, depreciations in the value of property are made available as against gross income. The methods prescribed for ascertaining such depreciations make necessary the adoption of an estimated unit of depreciation ascertained by reference to the cost of the property subject to the depreciations in question. Avoiding unnecessary detail, it may be briefly stated that the unit employed by this company for that purpose, in obedience to the requirements of the Treasury Department, is \$16.36 per ton, being the estimated average cost per ton to the company of its whole estimated commercial tonnage.

"The theory upon which these depreciations for exhaustions of ore are based is the well known economical principle, which has in numerous cases received judicial recognition and approval, and which should always be borne in mind by investors in mining property, namely, that unlike most other business projects, the earnings of a mine distributed in dividends are chiefly derived from exhaustions of the mine property in which the capital has been invested. Therefore, no matter how profitable the investment may prove to be, the dividends should not be regarded as profit in the ordinary acceptance of that term until the net amount realized shall have equaled the capital investment in the mine property. It will be observed that by reason of the adoption of a depreciating unit as required by the United States Treasury Department, it necessarily results that the net realizations in any year from the company's operations may be derived in part from exhaustions of assets and in part from apparent profits flowing from a net recovery per ton in excess of the estimated cost per ton."

It is interesting in this connection to observe that the unit adopted by the Nevada Hills Mining Co. is stated in the last annual report of that company as being \$42.57 per ton. As the average recovery per ton for the year is given at \$24.02, it is difficult to see where the tax collector comes in.

San Francisco, October 24.

CHARLES JANIN.

### GLOBE, ARIZONA

IMPROVED CONDITIONS.—MIAMI OUTPUT.—ELECTRIC RAILROAD FOR GLOBE.

Improved conditions in the copper industry are reflected in the increase in prospecting and mine development, and in general business, that has occurred in the past few months, and which is still continuing in the Globe and Miami districts of Gila county. The Globe hotels are filled nightly with mining and commercial men, the merchants all report increasing business, and the amount of freight hauled in by the Arizona & Eastern railroad last month is nearly 40% greater than for the corresponding month last year, most of the increase going to Miami, 7 miles west of Globe. The town is looking livelier than it has for over two years, and one is reminded of the 'good old days' previous to the sad years of 1910 and 1911.

The Old Dominion smelter is producing at the rate of about 30,000,000 lb. of copper per year, including production from ores from the Gibson and Black Warrior mines in the Miami district and from the Iron Cap and Superior & Bonton mines near Globe, besides intermittent shipments from smaller properties. Most of this production is from the mines of the Old Dominion company. The company is employing about 1200 men and is spending half a million dollars in the construction work in and around the mine and smelter. The Arizona Commercial is retimbering its Copper Hill shaft preparatory to resuming development work, the Iron Cap is exploring and developing through the Williams shaft, and the Superior & Boston continues exploration of the lower levels, with recent favorable results. Conditions at the two latter mines are more favorable than they have been for years, and both are making regular shipments of ore to Old Dominion. The old McMorris and Irene silver mines are being reopened, and many small copper and silver prospects are being developed.

It is in the comparatively new Miami district, however, and in the three-year-old town of Miami that the greatest activity is found. Where three years ago was a desert waste there now stands the town of Miami, with several hundred houses and business blocks and a population variously estimated at from 3000 to 4000. The town is growing more rapidly than ever before, and new buildings are going up on every block. Concrete is used in the construction of most of the business buildings, giving the town an air of permanency uncommon in mining communities. Dwelling houses are in great demand, and men working in the mines find it difficult to get a place to room. Miami was started on its career by the Miami Townsite Co., which is still selling lots and helping to build up the town. It is a corporation in no way connected with the mining companies, and the town is an independent one, distinguished in that respect from Ray, Morenci, and other copper districts of Arizona. Its foundation and the cause of its being is the extensive ore-body, averaging over 2% copper, that has been developed within a radius of two miles to the north and west by the Miami and the Inspiration Consolidated Copper companies and which gives the district an assured life of at least twenty years.

The Miami Copper Co. is now producing 35,000,000 lb. of copper per year, and this will probably be increased to over 40,000,000 lb. There are 18,000,000 tons of ore developed averaging 2.58% copper, and this tonnage is being increased by diamond and churn-drilling. The Inspiration Consolidated has proved 45,000,000 tons, averag-

ing 2% copper, and has started development and construction work involving the expenditure of \$7,000,000 during the next two years. Over 500 men are employed in and around the mines, and over 200 more in railroad construction, consisting of 11½ miles of track to the mines and the millsite. H. Kenyon Burch and staff are working on plans for the 7500-ton concentrator, power-house, and shops, and their construction will be started after the railroad work is a little more advanced. This work is now hampered by a scarcity of labor, consisting mostly of Mexicans and Indians. It is expected that Inspiration Con. will be producing 70,000,000 lb. of copper annually within three years.

Besides these mines, the Gibson and the Black Warrior mines are regular producers on a small scale and will contribute materially to the district's output. Southwestern Miami and South Live Oak are conducting churn-drill exploration over a large area of mineralized schist to the west of the Inspiration Con. mine, and while it is too early to draw definite conclusions, they have already obtained encouraging results. Some new development companies are in the process of formation, and many smaller prospects are being developed by their owners. There is a scarcity of labor in both the Globe and Miami districts

MIAMI, LOOKING SOUTHEAST.

owing to the fact that natives of the Balkan states are leaving on every train to fight for the fatherland. It is estimated that from 300 to 400 will leave within the next few days. The shortage will be accentuated by the additional fact that there will be no immigration from the Balkan countries for some time.

An electric railroad to connect Globe, Miami, and the Inspiration Consolidated mines is a probability of the near future. N. L. Amster, president of the Shannon Copper Co. at Clifton, owner of the famous R. R. R. mine at Patagonia, and who has extensive interests in Globe, including the Globe Light & Power Co., was in Globe last week in connection with the promotion of a company for building such a line. A franchise was submitted to and approved by a meeting of the citizens, and a committee was appointed to secure signatures to a petition to the board of supervisors asking that a special election be called at which the question of granting the franchise will be submitted to the voters of the county. Many citizens have agreed to take stock in the company if a franchise is granted.

Besides the Globe and the Miami districts, the country around San Carlos, 30 miles to the southeast, is attracting considerable attention because of favorable development at the Copper Reef mine, where the drift on the California vein, at the adit level, is in ore for over 300 ft. The ore is reported to have an average width of 5 ft. and carries 4% copper, \$10 gold, and \$4 silver per ton. Everything points to the advent of an era of unprecedented prosperity. When Inspiration Consolidated is producing at full capacity, the combined output of the mines at Globe and Miami will be from 140,000,000 to 150,000,000 lb. of copper annually, or from 12½ to 13½% of the production of the United States for 1911.

## LONDON

INCREASED RICHNESS OF KOLAR VEIN.—WORK AT APOROMA.  
—AFRICAN TINFIELDS.

Some years ago John Taylor & Sons tackled two auriferous districts in India, in addition to the Kolar, in Mysore; namely, the Dharwar in Bombay Presidency and the Anantapur in Madras province. The Dharwar has so far proved a failure. The Anantapur, however, may now be recognized as a successful undertaking. During the last few months the developments have been excellent. The ore reserve has been substantially increased. The ore-shoot that was first discovered in the 150-ft. level north of No. 5 shaft has been intersected by the 450-ft. level north of the North shaft. In this lower level the orebody has been proved for 283 ft., and cross-cuts have shown it to be as much as 57 ft. wide at one place. The average width of the level is 4 ft., and across this width the assay-value was 25 dwt. A winze below the level is 75 ft. deep and is still in ore of the same quality. The outlook is so satisfactory that 10 more stamps are to be erected, bringing the total to 30, having a capacity of 3000 tons per month. A tailing plant is being provided, and a new hoist capable of hoisting ore from 2000 ft. is nearly completed. To provide funds for this expansion of operations, 25,000 preference shares of £1 each were issued last October and readily absorbed by shareholders. This capital was also partly devoted to the extra development work. A pleasing feature of the position is that the average content of the ore treated has been steadily increasing. The output for September was 750 oz. from 2000 tons, both figures being the highest on record. While writing of Indian mining, I may mention that at the Champion Reef in the Kolar goldfield the recent developments in the deepest level, the 43rd, are reminiscent of the palmiest days of this mine. After an unchecked career of prosperity covering fifteen years, a poor zone was entered six years ago, and the dividends have been much lower ever since. Things have been improving again and the latest news, as recorded above, is most encouraging, as the lode is 6 ft. wide, averaging over one ounce per ton. The Kolar mines are noted for their alternating zones of richness and poverty. The pitch of the ore-shoots is very flat, and the question arises whether the successive zones of profitable ore are not a series of parallel flows.

South American gold placers occasionally attract attention in London. So far it cannot be said that any important success has been won, for the engineering difficulties in the Andes are varied and great. For instance the Apurima Goldfields is having a hard fight. The company was formed over two years ago to work a property in the province of Sandia, Peru. It had been worked many years ago by natives and by Spaniards, and their ditches are still of some engineering importance. Merricks, Crane & Co. are the engineers. Operations were commenced in December 1910 in connection with the water-supply, and enough of the work and the treatment plant was sufficiently advanced to start hydraulicking in February last. Unfortunately an unprecedently dry season followed, and regular work has not been possible since. However, a test clean-up was made on May 31 on 6000 cu. yd. of gravel, which yielded 46 oz. gold, or 8d. per cubic yard. The gravel washed came from the upper part of the face, which is 200 ft. high, so that the yield will probably be increased when the lower portions are worked as well. A mule-road from Phara, a distance of 35 miles, has been built. The deposit covers two square miles and varies in thickness from 50 to 400 ft. More capital has been required than originally estimated and the directors and the chief shareholders have provided the additional necessary funds. The cost of treatment is estimated at 2d. per cubic yard.

I have from time to time referred to the future prospects of the Transvaal, Swaziland, and Rhodesia as producers of tin. Two tin mines in the northern Transvaal are making profits and paying dividends, the Rooiberg and Zaaipplaats. The results of the past years work at Rooiberg have just been published and afford interesting reading.

Operations started in 1910 with 10 stamps, and in May of this year an additional 10 stamps were brought into use, together with treatment plant for accumulated middling and slime. During the year ended June 30, the old stamps treated 18,295 short tons of ore, and the new stamps 2504 tons, of which 789 tons was accumulated middling and slime.

## NEW YORK

LULL IN BUSINESS.—TRANSFER OF UNITED VERDE EXTENSION.—NEW COPPER.

The usual lull in general business which may always be expected to precede the presidential election has arrived on schedule time, and a waiting attitude prevails in all lines. The metropolitan press is filled with optimistic interviews concerning the outlook in various lines of trade, but the undertone does not speak the prosperity that is said to be so prevalent. In the copper-metal market the consumers, who have maintained a skeptical attitude, being somewhat strengthened therein by the producers' report published on October 8, are now refusing to buy, and for the most part the metal market is a nominal affair. Sellers have fixed the price at 17¾¢, and refuse to deviate therefrom. It is rather to be expected that an additional amount of copper will come in sight when October figures appear, as the shrinkage due to interruption of production at Bingham, and Ely, Nevada, will not make itself felt in the coming month's report.

The unwilling attitude of the public toward the share market is remarkable. The increase in the quarterly distribution by the Amalgamated Copper Co., the expectation of an early dividend to be paid by the Ray and Chino, have alike failed to incite the public to buy copper shares. Styles change in investments just as in everything else. At the moment by far the larger part of public buying is going into hydro-electric properties, more often than otherwise connected with public utilities companies, and industrial issues of various descriptions. In the case of the porphyry copper mines there has been some foreign selling within the past few days from holders abroad who, on account of the trouble in southeastern Europe, are selling anything that can be sold. Apart from copper-mining, market conditions are peculiar, in that the Eastern public has no centre of interest at this time, and the promotion of and speculation in mining enterprises generally is consequently at a low ebb.

The British Columbia Copper Co. is gradually absorbing the securities of the New Dominion Copper Co., its near neighbor. Within the past two months the British Columbia Copper Co. has invested nearly \$100,000 in New Dominion bonds, now owning more than a third of the entire bond issue. The American Smelting & Refining Co. is to have some competition hereafter in the selling of lead. The United Metals Selling Co. is to handle the lead production of the International Smelting & Refining Co., which has a lead stack at the Tooele plant and has also recently erected a lead refinery at East Chicago, just over the Indiana state line at the south end of Lake Michigan.

The United Verde Extension, at Jerome, Arizona, has been taken over, under a working arrangement for development, by a syndicate composed of James Douglas, Arthur Curtiss James, of the Phelps-Dodge company, Chester A. Congdon, George E. Tener, James Hoatson, of the Calumet & Arizona, John D. Ryan, of the copper world generally, and one or two associates. The United Verde Extension has been through many reorganizations, but at last is apparently started upon its way to success if the property develops into a mine. About \$225,000 has been provided in the reorganization to be expended in sinking a new shaft and in equipping the mine.

In view of the much-discussed question of new production of copper, it is interesting to note the latest step of the Rothschilds in securing new copper properties. The Rothschilds have for many years controlled the copper properties of Spain, the Rio Tinto and the Tharsis. The latter company has practically exhausted the deposits upon

its present holdings; though this is not a matter for surprise, in view of the fact that the first production of copper from these mines was in days so ancient that no record remains. Like the Rio Tinto, the Tharsis was worked by the Romans some two thousand years ago. The Tharsis management has been in every quarter of the globe in search of copper deposits and some recent purchases in Peru by the Paris branch of the house of Rothschilds are believed to have been made in the interest of the Tharsis. The search for a copper deposit to develop such as was made in this instance goes a long way toward justifying the present position of the copper producers, who claim that there have been no recent important discoveries, the greater part of the increased yield of the metal coming from metallurgical progress and not from the opening of new bodies of copper ore.

Alaskan properties are coming in for an increased share of attention. The Alaska copper yield for the year is expected to approximate 40,000,000 lb., as compared to 27,000,000 lb. for last year. The Kennecott or Bonanza mines are producing at the rate of about 23,000,000 lb. per year. A large low-grade property is in course of development by James Phillips, Jr., who was at the head of the Nevada Consolidated during its earlier days. It was Mr. Phillips who waged so strenuous a battle against the Utah Copper at the time the control of Nevada Consolidated was sought by the Guggenheim people. The Alaska property belonging to Mr. Phillips and his associates is on McCarthy creek near the Kennecott mines. Transportation is the chief problem, as is the case with the development of nearly all or any of the natural resources of Alaska. The Kennecott mines are in a fair way to earn the name of Bonanza in the fullest sense of the word; in February last the shareholders participated in a million dollar distribution, the first payment so made is now about to be followed by a second of two million dollars. While this return is large and dividends of three million dollars within eighteen months is apparently a very rapid return of capital outlay, it must be borne in mind that the Morgan-Guggenheim syndicate is credited with having expended some twenty million dollars in the construction and equipment of the railroad alone. A recent washout involved an outlay of fifty thousand dollars in repairs.

The predictions of the gradual decline of Cobalt production seem about to be realized. The Nipissing is still the biggest property in Cobalt, but has failed to develop new orebodies, though this failure has been compensated in part by the persistence of some of the veins which have been worked during the past year. La Rose, Trethewey, Temiskaming, and others are prospecting for new orebodies and must find them if they are to remain in the ranks of the producers any great length of time. Wetlaufer, the Lewisohn property, at South Lorrain experienced a bad break in the market this week, when the quarterly report appeared with the frank statement that dividends could not be long expected from the known ore reserves. Some of the traders are saying that there has been steady selling pressure in Wetlaufer for at least four months. Kerr Lake holds 150,000 shares of Wetlaufer in its treasury, and rumor has it very recently that part of this holding had been liquidated in the open market. The officials of the Kerr Lake emphatically deny that anything of the kind has taken place.

Figures just published by the Canadian Government show that during the first half of 1912 Cobalt produced 973,566 oz. less than during the similar period last year, but the rise in silver prices has saved the day for Cobalt and given it \$292,400 in profits more than it had up to June 30, 1911. The output for 1912 will be in round numbers about 30,000,000 oz., and receipts will be at least a half million dollars in excess of those of 1911. The Rochester Cobalt Mines, Ltd., is to be reorganized into the Rochester Mines, Ltd., on a basis of 4 shares of the old stock to be turned in for 1 share of new to be issued. The new concern will have a capital of \$1,000,000 and by reason of the exchange of stock will have a block of treasury stock for sale to provide development funds.

## DULUTH, MINNESOTA

LABOR SHORTAGE FROM BALKAN WAR.—CONCENTRATING IRON ORE.

Mining on the Mesaba range is comparatively active this year and indications now point to shipments to the lakes being continued into December, or as late as practicable. The scarcity of labor has not led the mining companies to increase the wage scale, but several properties have closed down and others are not working to full capacity. The trouble in the Balkan states has caused an emigration of Montenegrins and Greeks to enlist. Over 600 have already gone and this will tend to make the shortage greater. The Mesaba Electric railway is nearly completed and the laborers who have been attracted by the high wages offered will probably return to the mines and relieve the situation to some extent.

The Oliver Iron Mining Co., which operates the mines of the United States Steel Corporation, has relinquished its lease on the Great Northern lands, to take effect in 1915. These mines will be operated by the Arthur Iron Mining Co., which is already taking steps to develop a large number of new properties. Several large stripping contracts

STRIPPING AT THE OLIVER MINE.

have been let and it is reported more are to be let in the near future. The success of the large concentrator at Coleraine, of 20,000 tons daily capacity, for washing sand from the ore has led to experiments elsewhere over the range to ascertain if different low-grade ores were amenable to washing. While some negative results have been obtained, others have been found which would yield to treatment. A small plant of 3500 tons capacity is now operating on ore from the Hawkins mine at Nashwauk. A small experimental plant has also been constructed in Virginia by A. B. Coates, and others are contemplating plants. The silica content is reduced in the process sufficiently to bring the ore to the desired grade, and it is noticed that in nearly all cases the percentage of moisture is reduced at the same time. The moisture in the natural ore runs from 8 to 16% on the average while in the concentrate it seldom exceeds 6%. The question of moisture alone is receiving some attention. The dryer which has been constructed at the Brunt mine is said to be working successfully. The saving in freight pays a profit on the operation and the ore having once been reduced does not absorb any appreciable amount in transit.

## BOSTON

COPPER SHARES IN FRANCE.—THE LAKE SITUATION.

The forward market movement of the 'porphyry copper' shares was recently checked by the strike at Bingham and Ely and the Turco-Balkan war scare. Chino and Ray Consolidated, at a time when property conditions are reported to have never been more promising, suffered declines of four or five points, due to the heavy unloading of American stocks on the Continental bourses, the result of apprehension over the turn hostilities might take in the Near East. Chino has been rapidly developed, has at no time had any setback, and is known to be an excellent

mine. It is good for a long period of production, notwithstanding the fact that its predecessor, the Santa Rita, was one of the oldest copper mines in the United States, its history dating back for over a century. It is expected that Chino will enter the dividend class by the end of the year. The directors are expected to meet for dividend action just before the Christmas holidays, and it is reported that the stock will be placed on a \$4 per share annual basis by the declaration of a quarterly dividend of \$1 per share. Chino is after the world's laurels for low-cost copper production, having maintained a 6c. cost for the quarter ended September 30, applying to a production of over 10,000,000 lb. of copper. Ray Consolidated is reported to have quite a treasure in Ray Central ores, and is now producing at the rate of 3,000,000 lb. of copper per month with half of its mill facilities in operation. International complications of any kind are of more concern to the 'porphyry coppers' than any other class of Boston and New York mining shares, since it is estimated that around 300,000 shares of these stocks have been shipped to Paris and distributed among the proverbially thrifty French investors. Of this amount, probably half, or 150,000 shares, consists of Utah Copper. Miami comes next, with approximately 75,000 shares, and the remaining 75,000 shares are divided between Ray Consolidated and Chino in the approximate proportion of 50,000 shares of Ray and 25,000 shares of Chino. The *Boston Journal* states that French investors, on account of the war scare, 'threw over' from 20,000 to 25,000 shares of Chino. If this be true, there is not much Chino stock held in France at this time. The strength of Chino's market support was shown in the fact that interests close to the management absorbed the foreign-sold stock. It is thought in Boston that if the copper market will permit it, Chino sponsors will manipulate the stock to higher figures by the first of the year, thus emphasizing the company's advent upon its dividend-paying career. Strange to say, no liquidation of importance has been reported in Utah Copper and Miami, both of which are dividend payers. Not even the Utah Copper strike prompted French investors to sell what they regard to be a good dividend-paying investment issue. Miami is also closely held in France for the same reason. The burden of liquidation had to be borne by the non-dividend-paying mines, notwithstanding it is assured that Ray and Chino will become steady dividend payers soon. This market episode well illustrates the thrifty habits of French investors, who are far less inspired by speculative motives than Americans. Another point of interest about the French market for 'porphyry coppers' is that, with the exception of Miami, they are traded in on the Paris bourse in the shape of bearer certificates which have been issued by New York trust companies, the trust companies holding the stock certificates of the companies themselves. A considerable block of Miami stock in the original certificates has been sold directly in France, making it perhaps the closest held issue of all this group. Pond Creek Coal and Butte & Superior, Hayden, Stone & Co. specialties, have also been added to the Paris trading list.

The Lake market situation here remains mixed, and the possibilities are that this will continue for some time to come. To the Dow disaster and the Wolverine slump have been added weakness in Lake, which, from the prize copper speculation on the Boston board of three years ago, has declined into a commonplace and dubious issue. The recent selling of the stock was attributed to the attitude of the New York banks, some of which called for a reduction of loans on industrial and copper shares because of loss of cash to the sub-treasury and the receipt of a large shipment of American securities from abroad. It developed that Lake and other local coppers here have been carried on a margin more extensively than had been thought. Lake's troubles seem to be due to the swinging of the main Lake lode to the west, the lode growing leaner meanwhile. Some ore is being regularly hoisted from what is called the East lode, but that vein has not been

opened to any great extent because it can be developed more cheaply in connection with the work on the main lode. The East lode is maintaining the average of the rest of the property as to copper content, and is believed to have considerable possibilities.

### SALT LAKE CITY, UTAH

FAILURE OF BINGHAM STRIKE.—MOYER QUILTS.—AUGUSTIN PROCESS AT PARK CITY.

The backbone of the Bingham strike appears to be broken. The mines have resumed operation and are steadily increasing their crews at a rate which will soon reach the full quota. The Utah Copper Co., on October 26, had 1500 men employed, with 15 steam-shovels at work. Night work has been resumed regularly under search-lights, and the property is fast resuming its regular aspect. The United States, Ohio Copper, Utah Consolidated, Bingham-New Haven, and other properties have resumed and are making progress similar to that of the Utah Copper. The announcement that the Western Federation of Miners has practically abandoned its position at Ely, allowing strikers to return to work without opposition, while it is accompanied by statements that the battle will be continued at Bingham, is generally taken as a confession that the strike is recognized as a failure in Utah also. The refusal of the Butte union to contribute strike pay was another blow which has taken the heart out of the men at Bingham, although they have been receiving strike pay from the contributions of miners elsewhere. At the Magna and Arthur mills of the Utah Copper Co. men are being put on at about the same rate as at the mines. D. C. Jackling, the general manager, states that more than half the normal tonnage is now being handled and that the force will be steadily increased as added tonnage comes from the mines. The output is now running as high as 11,000 tons of ore per day, compared with a maximum capacity of 20,000 tons.

The failure of the Bingham strike, it is generally believed among operators and others, will seriously injure the prestige of the Western Federation of Miners and have an effect on the labor situation in mines all over the West. At present the officials of that organization, notably C. H. Moyer, the president, are seeking to clear their skirts by maintaining that the strike was entered into at the outset contrary to their advice. Men close to the Federation head are declaring that he opposed the strike in the early councils, and yielded only in the face of overwhelming sentiment among the men. This is to a large extent true. It is understood that Moyer was afraid from the start that he would not be able to hold together the men of different nationalities who make up the Bingham miners. He deserted early in the game, leaving Yanco Terziel, of the executive board, in charge. There has been a comparative absence of the usual dynamiting tactics. In fact, to date no attempts have been made to blow up any of the works, although there have been some exchanges of shots between strikers and guards. Whether there will be more serious attempts at violence before the strikers finally surrender is, of course, still a question. In any event, the hold of the Western Federation on Bingham has already been loosened, if not practically removed.

Metallurgists are watching with much interest the work of the Mines Operating Co. in solving the problem of treatment of the ores of the old Ontario at Park City under its ten-year lease. In former times these ores were treated by a chlorination process. The ores now being treated by the lessees were too low in grade for successful handling under the old method. The Mines Operating Co. experimented with cyaniding at first, but it was found that too much of the silver was escaping, although the gold was satisfactorily extracted. To get out the silver the company is now dry-crushing, giving the ore a chlorination roast, and then leaching by the Augustin process, which is said to be giving satisfactory results.

## General Mining News

### ALASKA

#### CORDOVA

The output of the Ruby district will be about \$100,000 this season, according to J. Zug, of the Alaska Road Commission. Practically all this came from Long creek, from which the largest amount of gold was won from the Windy bench, opposite Discovery, where T. McKinnon and associates are working. They recovered \$24,000 during the season, while others got from \$2000 to \$6000. Nearly all the production of the district is made without machinery, there being but one 30-hp. boiler on the creek.

#### FAIRBANKS

The Pioneer Mining Co. will have its 5-stamp mill at work within a few days. A shaft has been sunk 100 ft., and a drift driven 150 ft. on the vein, on which stoping has been started. It is about 12 in. wide and carries good gold content. Over 500 ft. of sinking and driving has been done at the Woods and Olsen property on Mineral creek, and the vein is 12 ft. wide, averaging \$20 per ton. A 40-ton mill will be built in the spring and will be driven by electric power, water for which can be obtained from the stream flowing from a glacier nearby. Rich gravel has been discovered on Ester creek and is supposed to be a continuation of the ground being worked on the right limit of Ready Bullion creek, a tributary of the Ester. Work at the Biglow claim, on Goldstream, has been stopped for the season, water being scarce; in fact, it has been so right through the past season. The output from the claim is estimated to be \$250,000. There is a big block of ground to be taken out yet, and this will be washed next spring. The Niggerhead claim recovered \$9000 in its clean-up.

#### JUNEAU

During September the 240 and 300-stamp mills at the Alaska Treadwell mine worked 29.70 and 29.65 days, crushing 31,724 and 47,712 tons, and producing 547 and 1007 tons of concentrate, respectively. Gold saved by amalgamation totaled \$91,985, and from concentrate treatment \$85,915, with a total realizable value of \$176,121. Operating expenses were \$82,100, and construction \$15,512, leaving a net profit of \$78,509. Development covered 928 ft., and the stock of broken ore decreased 25,798 tons.

#### NOME

There has been great disappointment among litigants who have been fighting for possession of the Bon Voyage claim during the past year. The dump was estimated to be worth \$100,000, and on being washed only yielded \$30,000. The gold is being held by the bank pending settlement of new suits. Local opinion is that the lawyers will get everything and the litigants nothing.

### ARIZONA

#### GRAHAM COUNTY

The Detroit Copper Co., of Morenci, has purchased all the property belonging to the New England Copper Co. The transfer embraces 125 claims about five miles north-west of Clifton. The ores are mainly chalcopryrite and chalcocite, carrying a little gold and silver.

#### YAVAPAI COUNTY

(Special Correspondence.)—The Jerome Verde Oil Co. reports that its drill has entered the artesian-water stratum at a depth of about 1000 ft., and the flow of water is bringing up about 1 gal. of high-grade oil per minute. The water will be cemented off and drilling resumed. T. C. Snider has secured the contract for grading the railroad from the U. V. tunnel to the new smelter site at Clarksville, as the new town is to be named, a distance of nearly nine miles. Mr. Snider will also grade the smelter site. Several hundred men will be started at once. Prescott, October 26.

It is stated that the Bagdad Copper Co. has been financed

and will resume work at once. Development will include much drilling, and driving an adit about 8000 ft. in length, which will be connected with existing adits in the group. A large concentrating plant will be erected similar to that at Ray.

### CALIFORNIA

#### AMADOR COUNTY

Sinking was commenced last week at the Kennedy mine, and the shaft will be sunk 150 ft. farther to 3900-ft. depth, taking about 90 days to complete. At the South Jackson mine the shaft is now 50 ft. deep, and will be sunk 100 ft. farther before opening out. The 79th dividend, of 5c. per share, has been paid by the Bunker Hill company. This amounts to about \$10,000, and during the past six years over \$750,000 has been paid. It is stated that the last clean-up at the South Eureka yielded \$14,000 net profit, but does not include operations at the Oneida property.

#### NEVADA COUNTY

If a permit is obtained from the Débris Commission, the Manzanita Hydraulic company will resume operations. It is intended to impound debris in the old pit at the mine. Water will be obtained from the new ditch being built from Deer creek, about eight miles from Nevada City, to the old pit at the mine, about a half-mile north of the city.

#### PLACER COUNTY

It is stated that an electric smelter is to be erected near Colfax to treat the large deposits of low-grade gold-bearing ores in this and neighboring counties. With the completion of the great dam of the Pacific Gas & Electric Co. at Clipper Gap, electricity will be cheaply generated. This company has 1200 men working at Cisco at present, and intends to enlarge the supply ditch from 2000 to 14,000 miner's inches below the dam.

#### PLUMAS COUNTY

The town of Quincy has had two fires within one week, the second one occurring on October 23 and resulting in \$11,000 damage. The adit at the Berry Creek mine is in 100 ft. in hard formation, and the mill erected last spring is working full time.

#### SACRAMENTO COUNTY

The clean-up from the first 8 days' operation of the Natomas Consolidated Co.'s new dredge, No. 10, yielded \$16,500.

#### SAN BERNARDINO COUNTY

(Special Correspondence.)—The Skidoo Mines mill lost 10.66 days during September, and crushed 580 tons of ore for the company and 460 tons for lessees. The total revenue from mill, cyanide, and custom treatment was \$10,724. Working expenses were \$4530 and development \$518, leaving the month's profit as \$5676.

Los Angeles, October 28.

#### SIERRA COUNTY

There is some likelihood of the Rising Quartz mine, at Alleghany, being reworked after a long period of idleness. It is connected with the mill by aerial tramway. The plant only worked a short time, and was then shut down. J. W. Finch, of Denver, and W. J. Morris, of Grass Valley, have examined the property lately. The mill at the Kate Hardy mine is nearly finished. Two tables will be installed to save pyrite. A transformer station has been erected at the South Fork mine. The main adit is to be lighted, and an air-compressor driven by electricity will be installed. The first orebody to be opened is in 1500 ft. from the portal of the adit. An important discovery of gravel has been made near Nigger Tent, at a depth of 50 ft. It is identical with that found in the Orient mine.

#### SISKIYOU COUNTY

(Special Correspondence.)—The Yreka Development Co. is prospecting a coal deposit on the Henry Hougden ranch, four miles north of Montague. The mineral is lignite, and the 20-ft. shaft has disclosed a 40-in. seam.

Tests recently made with the product by the Yreka Steam Motor Railroad Co. showed satisfactory heating properties. Considerable water is in evidence as prospecting advances. J. W. Barham is president. The Vere Gold Mining Co. is installing a placer plant at its holdings near Hornbrook. The property embraces 20 acres, situated on the Klamath. Oakland people are largely interested. V. Wilson is superintendent. The Portuguese placer claims, six miles from Selad, have been bonded to the Jerome Mining Co. of San Francisco. The cemented surface gravel has handicapped operations in the past. Yreka, October 19.

#### TRINITY COUNTY

The new dredge of the Trinity Dredging Co., which cost \$150,000, has been working for two weeks, and has proved satisfactory. Fourteen men are employed. C. J. Meade and T. Friend, who have a claim on Big Ryecroft creek, a tributary of the Trinity river, have uncovered a large vein which shows rich ore. In Ames gulch, about eight miles from Lewiston, S. Williams and J. Clayton are erecting a 5-stamp mill to crush their ore.

### COLORADO

#### LAKE COUNTY (LEADVILLE)

In the early days of this district, ore which was under \$30 per ton was either used to fill stopes or put on the dumps, due to high smelting and other charges. At present many old stopes filled with this ore are being mined by lessees at a fair profit, and dumps also are being worked over for the same purpose.

The lost drill-hole at the St. Louis adit, Breece hill, has been found, and the shaft drained. Sinking is in progress, and from the adit-level the shaft will be sunk 450 ft. The formation in the shaft is porphyry, and water is not troublesome. Work at Breece hill has been encouraged by opening a good orebody of carbonate of zinc in the Little Johnny claim. The Big Four company has resumed operation, principally on the 400-ft. level. The Winthrop Mining Co., Birdseye, will extend the Crescent adit, which is in 1300 ft. Connections have been made with the upper adit and shaft.

#### TELLER COUNTY (CRIPPLE CREEK)

Sampling of El Paso mine by T. A. Countryman is finished, after nearly three months work. Water is receding from the Mary McKinney shaft at the rate of four inches per day. One of the most profitable leases in the district is that of Pervis & Caley, on Block 239 of the Stratton estate, who are shipping about four cars of ore per week, which returns over 3 oz. per ton. This ore comes from 110 and 160-ft. depth, where the vein is 4 ft. wide, of which about 20% is sorted as waste. The shaft is 210 ft. deep, and at 220 ft. a station will be cut. The weather has been favorable to dump lessees generally, and those of the Isabella are said to be doing well. Water in the Gold Coin shaft has receded to within 7 ft. of the top of No. 11 level. The Blue Bird shaft, on Bull hill, is 1770 ft. deep, and is the deepest in the district, and water is receding about 3 in. per day. It is stated that the Little Giant mill, in Pony gulch, will be removed to the El Oro, in Eclipse gulch. Development at the Gold Dollar is proving satisfactory, and dividends may be paid every three months.

### IDAHO

#### SHOSHONE COUNTY

During the year ended August 31, 1912, the total production of the Federal Mining & Smelting Co.'s mines was valued at \$4,911,996. Mining, development, and smelting totaled \$4,053,730, leaving net profits at \$858,265, and after adding other income and deducting general expenses the balance was \$895,429. Out of this \$749,131 was paid in dividends, leaving \$146,298 surplus. The profit and loss account surplus stands at \$1,324,026. The Morning mine has given an increased profit of \$201,419, as compared with the previous year. Work at the mine is satisfactory, save the shaft, which has given a little trouble. At Wardner

the profits have been good, but the area of ground to be opened for ore reserves is limited, and profits from the Omaha lease have ceased for the present. The old property at Mace is of little value, but the work on the Cleveland-Green Hill lodes will add considerably to the life of the property. The necessity for the company to procure more ground is apparent, and an option has been taken on the Phi Kappa group of claims in Custer county, where development is now under way.

At 8 o'clock on the morning of October 24 a skip in the White raise of the Bunker Hill & Sullivan mine, got out of control and dropped to the bottom, 300 ft. below, with 12 men, 11 of whom were injured more or less. It is stated that the friction brake failed to hold, and the hoistman did not apply the safety brake in time to stop the skip getting up speed. The first-aid training came into good service for this accident. The body of F. Bentz, the missing pumpman, who was lost in the fire of October 7, was found on October 26, on No. 13 level. It would appear that he stuck to his post until forced to escape from the smoke which resulted from the fire. Recent development in the Idora Hill mine, on Sunset peak, near

GLIMPSE OF COEUR D'ALENE. KELLOGG PEAK IN CENTRE.

Wallace, has exposed two new veins on the 600-ft. level. The formation is not slate, as has been contended, but quartzite similar to other Coeur d'Alene properties. The veins carry galena free from blende. Shipments will be sent out as soon as possible.

The annual meeting of the Caledonia Mining Co. was held at Wallace on October 11, and the following are the more important details of results shown:

Ore produced, tons .....	18,391
Metal production:	
Silver, 1,209,432 oz., valued at.....	\$646,728
Gold, 1.6 oz., valued at.....	33
Lead, 9,069,845 lb., valued at.....	332,886
Copper, 127,253 lb., valued at.....	9,808
Total value .....	\$989,455
Freight, treatment, and royalty.....	377,147
Net value of shipments.....	\$612,308
Cost of mining, development, power, etc.....	408,785
	\$203,523
Litigation with Bunker Hill company...\$28,220	
Keating adit, depreciation, etc.....	39,665
	\$87,885
Net profit .....	\$115,638
Dividends paid .....	52,100
Surplus, with \$130 interest, etc.....	\$63,668
The injunction secured against the company by the Bunker Hill company covers all ore developed in the work-	

ings. A demurrer to their complaint has been filed; and it is not certain when the case will be tried. The Caledonia and O'Connor claims only yielded ore worth \$79,271; while the Omaha lease produced \$910,183.

## MISSOURI

### JASPER COUNTY

During the week ended October 20 the output of blende was 11,020,330 lb., and 1,732,140 lb. of lead. The highest settlement for zinc ore was \$61 per ton, and \$27 to \$32 per ton for calamine ores of 40% zinc. The fuel situation is growing serious, and gas pressure has been low. Chapman and Lennon, working the old Prudential ground at Galena, have unwatered it by means of a siphon, dispensing with steam or electric pumps. The Waneta Pearl Mining Co. has five drill-holes in ore. In the last hole bored, ore was cut at 70-ft. depth, and 9 ft. averaged 15% of lead. At 84 ft. zinc ore was cut, and to 120 ft. averaged 35% of zinc and lead. Mention was made recently in these columns of drilling to be done by the Granby company, and 19 holes are in ore, although of no great value. Below 200-ft. depth nothing was found. In 1911 Missouri produced 640,000 lb. of copper, a by-product from treating lead ores of St. Francis county. A boiler exploded at the Joe Lewis mine and did considerable damage.

## MONTANA

### SILVERBOW COUNTY

(Special Correspondence.)—The Butte & Zenith Mining Co. has been formed with a capital of \$3,000,000, divided into 300,000 shares of \$10 each, by Duluth capitalists, to prospect and develop the country five miles west of Butte and two miles beyond the old Blue Bird property. W. H. Weed has examined the claims, and the report seems to have been satisfactory, as the company was organized and surface equipment ordered. The new hoist at the Butte & Superior is almost ready for work. It will have a capacity of 2000 tons per day from a depth of 3500 ft. Improvements to the second section of the concentrator are practically completed, while No. 1 section is treating 500 tons of ore per day. The extension of the Butte, Anaconda & Pacific railroad to Georgetown is finished, and ore will be sent from the Southern Cross and other mines in the district to the Washoe smelter. The Butte Central company's concentrating plant will probably start early in December, and will treat 100 tons per day. W. A. Clark is laying foundations for a concentrating plant just south of Butte, and will work through the winter.

Butte, October 28.

## NEVADA

### CHURCHILL COUNTY

(Special Correspondence.)—The Nevada Hills mill treated 3915 tons of ore in September, yielding \$82,647, at a cost of \$32,856, leaving a profit of \$49,791. The gross value was \$23.13 per ton, loss in residue \$2.02, and costs \$8.39, the net profit being \$12.72 per ton. Balance due to Bank at October 28 was \$175,000; \$50,000 having been paid during the past month. The financial statement shows liabilities to be \$94,000 over liquid assets.

Reno, October 28.

### ESMERALDA COUNTY

The Goldfield Consolidated and Tonopah & Belmont Development companies have filed a complaint against railroad companies for excessive freight charges on cyanide. The suit was heard at Reno last week, before Mr. Pugh, of the Interstate Railroad Commission. It involves \$30,000, the difference between \$2.37 and \$2.08 per ton, the price charged, and \$1.15 per ton, the rate which should have been applied. It is proposed to consolidate the leading properties in the Diamondfield part of the Goldfield district. Only 10 of the 20 stamps at the Bonnie Claire mill are crushing ore from the Polverde mine of the Jumbo Extension Co. Five Johnston vanners are to be installed and the mill will then handle 100 tons per day. The best ore in

the mine has been opened by a winze below the 850-ft. level, which will be connected by the 930-ft. level drift. The ore being treated averages over \$20 per ton. At the Merger, the 1330-ft. level cross-cut developed a flow of water equal to 30,000 gal. per day.

The Vernal, in the Diamondfield district, and adjoining the Goldfield Belmont is doing some development which should be of value in proving the importance of the district.

At the Big Four, Manhattan district, two raises driven 30 ft. above the 400-ft. level, have proved 10 ft. of ore averaging \$75 per ton. The Joshua Hendy Iron Works of San Francisco has a contract for the new mill, which is to be finished by January 15, which, according to local opinion, is rushing the work too fast.

### LINCOLN COUNTY

The Home Run mine came into notice several months ago by the discovery of several large caves filled with first-class copper and silver ore. They were opened by a vertical shaft and incline from the 90-ft. level down. Later the incline was extended to the surface, being a better way to get the ore. The 90-ft. level was continued past the ore pockets and has cut 4 ft. of good ore. The same vein is being opened on the 150-ft. level, where 4 ft. of copper ore averages \$70 per ton. Ore shipments are being made regularly.

### LYON COUNTY

Shipments from the Ludwig mine of the Nevada-Douglas company have averaged 5% of copper during October, and 3.75% from the Douglas Hill mine, while daily shipments are 400 tons. Over 20 men have been dispensed with lately. New ore-bins at the Douglas Hill are finished. In the Ludwig, the 100-ft. level is being driven south, and is at present in high-grade carbonate ore about 7 ft. wide. Generally, the outlook is satisfactory. The Kennedy Consolidated copper property, at Buckskin, Douglas county, has been acquired by the Nevada-Douglas company, at a cost of \$105,000, payments to extend over several years. Los Angeles people have a lease on the Kennedy property, but its transfer does not affect them. It is situated about six miles from the Nevada-Douglas mines. During the week ended October 17 the Thompson smelter handled 6217 tons of ore, of which 2845 tons came from the Nevada-Douglas. Twelve cars of matte were sent out during the week.

### NYE COUNTY

Fire destroyed the sub-station of the Nevada-California Power Co. on October 30, and all the mines and mills at Tonopah were shut down, but it was expected that the temporary connections would be made during the day. The damage is estimated at \$50,000 and the outbreak was due to a short-circuit in one of the transformers.

During the week ended October 26, eight mines at Tonopah produced 10,390 tons of ore valued at \$259,750. At the Belmont, the east drift on No. 13 level has cut rich veins of sulphide ore. Shipments of bullion were 69,045 oz. valued at \$56,916. The Montana has cut two new ore-bodies on the 565-ft. and one on the 615-ft. level. The North Star has shipped 50 tons of ore worth \$60 per ton from the 850 and 1250-ft. levels. Development at 1000 ft. in the Halifax is very encouraging. The new 150-hp. motor for the North Star tube-mills is being installed. An 18-drill compressor has been purchased and a concentrate drier is being built.

### STOREY COUNTY

On the 2500-ft. level of the Sierra Nevada the vein has opened to a width of 7 ft. assaying \$17 per ton. Two cars of ore averaging \$50 and \$164 per ton were saved, also 300 lb. of specimen ore of high value. The Mexican mill treated 482 tons, worth \$27.39 per ton, with 94% extraction. The Crown Point produced 542 mine-cars of ore from the 1400-ft. level stopes, having a gross value of \$7000. The Yellow Jacket mill has been running during the past week on Point ore, 727 tons being in the bins. The Ophir cyanide plant is working full time with good results. At the C. & C. shaft the Reidler pumps worked

65, 130, and 139 hours, respectively; the two centrifugal pumps at the 2310-ft. station, 159 hr., and the pump at 2500 ft. 159 hr. Necessary repairs were made to the shaft. On the 2100 and 2475-ft. stations at Ward shaft removal of pumps, motor, and pipes is in progress. A. Elkins was badly scalded with hot water at the 2475-ft. station on October 24 and died soon after.

#### WHITE PINE COUNTY

The ill-advised strike at the Nevada Consolidated mines was declared off on October 28, the men returning to work at the rate of wage offered on October 1, which gave an increase of 25c. per day to all miners and laborers.

### NEW MEXICO

#### GRANT COUNTY

The electric plant being installed at the Emma copper mine, at Fierro, by the Phelps-Dodge company, will soon be in operation. Development continues to open rich ore. Chino produced 3,549,862 lb. of copper in September, this being the first month that the mine and mill were in full operation.

### UTAH

#### JUAB COUNTY

The Dragon Iron mine is shipping 100 tons per day to the United States smelter. This ore comes from the 300-ft. level, while it has been opened on the 600-ft. level. The shaft is down 1025 ft., and indications are promising for more iron ore. During the past week the east drift on the 2300-ft. level of the Grand Central cut the orebody which, on the level above, carried high-grade copper ore. Assays taken along the lode return \$8 per ton. The new ore-house, of 300-ton capacity, at the Eagle & Blue Bell, is now in use and will make the handling of ore much easier than in the past. Lessees at the New Bullion, in the North Tintic district, are shipping zinc ore, while at the Gemini 100 men are working as lessees. The October production should be 1500 tons of ore. The Seranton mine is to use electric power, and a contract has been made with the Telluride Power Co. for a supply. Owing to car shortage, several of the Tintic mines have been unable to ship ores lately.

#### SALT LAKE COUNTY

On account of the strike during the second week in the month, the September copper output of the Utah Copper company was only 6,965,144 lb., against 11,841,044 lb. in August.

#### SUMMIT COUNTY

The new treatment plant of the Mines Operating Co. at the Ontario mine, Park City, is doing satisfactory work. The process consists of dry crushing, chlorinating roasting, and leaching by the old Augustin method. Experiments on roasting were carried out at the Consolidated Mercur mill and the University of Utah by a new process invented by N. C. Christensen and T. P. Holt, of this state. The two roasting-furnaces built will only treat about 75 tons per day, so others are to be constructed. Otherwise the plant is a success.

#### TOOELE COUNTY

Since the new railroad was built to the Ophir district there has been renewed activity at many of the mines, many new discoveries have been made, the mill at the Ophir Hill property is well on toward completion, and shipments have been increasing. The Ophir Hill is sending out regular lots of concentrate from its dump, the Cliff is also shipping a good tonnage, and rich ore is being mined at the Lion Hill Consolidated property. At this mine the Monogram drift is being driven from the 1300-ft. Chloride Point adit to open the south and west portions of the mine. In the Monogram drift ore assaying 500 oz. of silver and \$2 to \$4 per ton in gold has been opened. At the Eastside adit, on the north end of the

property, a raise has cut what seems to be a series of cavities, which are filled with soft ore composed of chloride and hornsilver, assaying from 142 to 208 oz. of silver per ton. The ore has been opened for 30 ft., and is continuous. About 20 men are employed and four machine drills.

### WASHINGTON

#### STEVENS COUNTY

The June-Echo Mining & Milling Co. has been incorporated with a capital of \$1,500,000. The property consists of the June and Echo claims, situated two miles from Chewelah in the old district of Embreetown. Thirty years ago the first silver ore was taken from the property and hauled by wagon to Spokane. Different managements have had control in later years.

### CANADA

#### BRITISH COLUMBIA

(Special Correspondence.)—At a depth of 250 ft. in the shaft of the Blue Bird, near Rossland, 7 ft. of high-grade ore has been opened. At 220 ft. the vein was from 9 to 36 in. wide, carrying galena, while at the present depth copper is showing strongly. During the first nine months of the current year mines in the Kootenai and Boundary districts of British Columbia have paid \$932,000 in dividends, to which Le Roi No. 2 contributed \$30,000.

PART OF BRITISH COLUMBIA, SHOWING MINING DISTRICTS.

Nickel Plate \$180,000, Standard \$325,000, British Columbia Copper Co. \$177,000, and Canadian Consolidated \$220,000.

Spokane, October 25.

(Special Correspondence.)—At the Coronation mine, on Cadwallader creek, Lillovet, the raise from No. 4 to No. 3 level is finished. The vein averaged 14 in. wide for 89 ft., and 50 to 60 tons of ore worth \$175 per ton was saved. On No. 4 level driving is in progress at both faces, where the vein is 18 in. wide, with free gold and sulphides showing. At the Countless, an adjoining claim of the company, the adit is in 490 ft., in diorite, and progress is slow. The Little Joe vein should be cut within 35 feet.

Victoria, October 25.

At the Hidden Creek properties of the Granby company extensive diamond-drilling is under way. On No. 2 orebody a drill has passed through 95 ft. of ore below the adit level, which assays 2.91% copper, while the drill on No. 1 orebody is down 105 ft. in ore averaging 3% copper. The net earnings of the company in September were \$181,500. During the past week the president and vice-president of the Hedley Gold Mining Co. visited the Nickel Plate property. Prospecting by diamond-drill has enabled further development to be mapped out. It has

been decided to sink a new incline from No. 4 adit, and will be large enough for a double skipway and a manway. It will serve the new orebodies found in the low levels of the mines. Another 150-hp. boiler is to be installed, while the general power question is being considered.

#### COBALT

Development at La Rose has resulted in finding the Cobalt Lake fault at the 380-ft. level. The work here was done from a winze in which Keewatin chert was cut, but is now in conglomerate. A vein 2 ft. wide is being driven on, but at present contains no silver. At the Fisher-Eplett property of La Rose four veins are being opened on the 200-ft. level. They are of calcite and quartz in the Keewatin formation. During the week ended October 19 ore shipments from Cobalt totaled 420 tons, making 18,022 tons for the year to date, while shipments of silver amounted to 161,297 oz. The Kerr Lake company has declared a dividend of 25c. per share, payable December 16. During the first eight months of 1912 La Rose has produced silver valued at \$1,101,849, while the net income was \$600,745. The surplus now stands at \$1,783,885. On the 200-ft. level of the Crown Reserve the branch vein shows 2 in. of calcite and cobalt assaying 3500 oz. of silver per ton. During the year ended August 31 the Kerr Lake company produced 1,885,495 oz. of silver, compared with 2,388,420 oz. during the preceding year. The net profits were \$769,175, against \$937,379. Cost of production was: mining, 12.10c. per ounce; shipment and treatment, 5.55c., and general 0.65c.; a total of 18.30c. per ounce of silver recovered. Development covered 8481 ft., the greatest amount being done on the 140-ft. level of No. 7 shaft. Rich ore was opened on the 225-ft. level. Ore reserves on September 1 were estimated to contain 6,660,091 oz. of silver.

#### DAWSON

An overland mail service has been arranged for the Dawson district for the present winter, and all classes of mail may be sent in as soon as there is an improvement.

### MEXICO

#### SONORA

(Special Correspondence.)—During September the old mill of El Tigre worked 61% of the time, crushing 1500 tons of dry ore, and the stamp-mill ran 75% of the time, crushing 2767 tons of dry ore, while the cyanide plant treated 4150 tons of current and 1125 tons of dump tailing. The total output from shipping ore, concentrate, and cyanide plant was valued at \$85,620. Costs amounted to \$57,732, leaving a net profit of \$27,888. Taxes were \$4668. The poor profits for September were due to the effects of the revolution near the mine, while metallurgical results were better than during any previous month.

Kansas City, Missouri, October 19.

During the first six months of 1912 the subsidiary companies of the Mines Company of America received from sales of bullion \$1,309,913, while expenses aggregated \$949,509, leaving an operating profit of \$360,404. After deducting general expenses and taxes, net profits were \$343,932. The balance sheet of the subsidiary and holding companies shows supplies, bullion in transit, cash, etc., amounting to \$1,934,073. Liquid assets over liabilities are \$852,809, and cash and accounts receivable by the Mines Company are \$229,438, making a total of \$1,082,247. At the last meeting of the directors, the dividend was passed, and in view of the present conditions in Mexico the large cash surplus seems to be the right policy.

#### PERU

The New Chuquitambo Gold Mines, Ltd., near Cerro de Pasco, has started to sink an inclined shaft to open its ground below the Santiago adit, hoping thereby to find the ore it has been working above this level. From 2000 to 3000 tons of ore is being crushed monthly. This is low grade but profitable, but there have been difficulties on account of the presence of copper. Experiments are being made to overcome this trouble.

## Personal

Professional men are invited to send news of their engagements and travels. Such news is interesting to friends.

I. E. ROSE is in San Francisco.

W. P. SIEBERT is at the Palace.

C. A. NONES is here from the East.

M. J. MONETTE is at the St. Francis.

F. B. CALDWELL is here from San Dimas.

R. N. BISHOP has been in Nevada recently.

BARNEY RONONDO has returned from Alaska.

T. G. PATTON was in San Francisco recently.

THEODORE BOUCHELLE has gone to Nicaragua.

A. K. TIERNAN has returned to Salt Lake City.

G. H. GARRY was at Knoxville, Tennessee, recently.

ERROL MACBOYLE has returned from the Southwest.

C. T. NICOLSON left Nome on October 30 for San Francisco.

W. O. NORTH has returned to Los Angeles from Singapore.

W. H. LATIMER, of Los Angeles, was here during the week.

H. D. BODDINGTON has left London and is now at El Paso, Texas.

J. T. HODSON has returned to Salt Lake City from a trip through Nevada.

H. FOSTER BAIN is in Denver and expects to reach San Francisco on Tuesday.

E. L. GODBE has returned to Salt Lake City from a business trip to New York.

ALGERNON DEL MAR was in San Francisco and has returned to Los Angeles.

T. SKEWES SAUNDERS has returned to La Aurora, Mexico, from a trip to Europe.

E. T. DUMBLE, chief geologist of the Southern Pacific railroad, is in San Francisco.

H. B. SHERRICK, manager of the Mars mine in Nicaragua, has returned from his vacation.

D. W. JESSUP has resigned from his position with the United States Mining Company.

H. KENYON BURCH was at Los Angeles and returned to Globe, Arizona, early in the week.

R. G. SMITH is returning to San Francisco on the last steamer leaving Nome this autumn.

VAN H. MANNING was in San Francisco early in the week and has returned to Washington.

E. D. McDERMOTT is now with the South Urals Mining Co., Tanalyk, Orenburg Government, Siberia.

R. P. McLOUGHLIN has gone to the White Pine district of Nevada and will remain two or three weeks.

F. L. SIZER is visiting the Clifton-Morenci district and expects to come to San Francisco about November 10.

HERBERT GREGORY, geologist of the Yale Peruvian expedition, was in Arequipa recently and has gone to Cuzco.

A. W. McCUNE has returned to Cerro de Pasco from an inspection of the route of the projected Amazon-Pacific railway.

C. DAWES CLARK is engaged in professional work in New Mexico, expecting to return to New York early in December.

W. H. RADFORD has returned to San Francisco from Alaska, where he has been for the past six months on professional work.

D'ARCY WEATHERBE left Arequipa, Peru, about the middle of September for a two-months trip to Cuzco and the Apurimac river.

GUILLERMO HILEMAN has been appointed field manager of the Government oil wells in Argentine Republic, with headquarters at Buenos Aires.

ARTHUR THOMAS and WALTER NEBEKER have been appointed as the representatives of the Salt Lake Mining and Stock Exchange at the Mining Congress at Spokane.

## LOCAL METAL PRICES

San Francisco is not a primary market for the common metals except quicksilver. The prices quoted below therefore represent sales of small lots and are not such as an ore-producer could expect to realize. Ore contracts usually call for settlements on the basis of Eastern prices, less freight and treatment charges. The prices quoted are in cents per pound, except in the case of quicksilver, which is quoted in dollars per flask of 75 pounds.

San Francisco October 31.

Antimony.....	11-11½c	Quicksilver (flask).....	41.50
Electrolytic Copper.....	18-18½c	Tin.....	52-53½c
Pig Lead.....	5.35-6.30c	Spelter.....	8½-8¾c
Zinc dust, 1400 lb. casks, per 100 lb., small lots \$9.50-9.75; large \$7.50-8.50			

## METAL PRICES

(By wire from New York.)

NEW YORK, October 31.—On account of the European situation the copper market continues to be easy. Lead is weak, since a good deal of Western lead is being pressed for sale. Spelter is also weak, as the smelters are anxious to make sales. Average daily prices for the past week, in cents per pound, based on wholesale transactions, standard brands, are given below.

Date.	Electrolytic Copper.	Lead.	Spelter.	Silver, per oz.
Oct. 24.....	17.35	5.08	7.28	63½
" 25.....	17.35	5.08	7.28	63
" 26.....	17.30	5.08	7.28	63
" 27.....	Sunday. No market.			
" 28.....	17.30	5.06	7.28	63
" 29.....	17.25	5.06	7.28	63½
" 30.....	17.25	5.06	7.28	62½

## SILVER

Below is given the average New York quotation, in cents per ounce, of fine silver for the months indicated:

	1911.	1912.	1911.	1912.
Jan. ....	53.81	56.25	July .....	52.57
Feb. ....	52.23	59.06	Aug. ....	52.17
Mch. ....	52.76	58.37	Sept. ....	52.43
Apr. ....	52.32	59.20	Oct. ....	53.37
May ....	53.31	60.88	Nov. ....	55.77
June ....	53.04	61.29	Dec. ....	54.85

## COPPER

Daily quotations on copper as published in this column represent average wholesale transactions on the New York market and refer to electrolytic copper. Lake copper commands normally from 1-5 to 1-4c. per lb. more. Below are average monthly quotations in cents per pound:

	1911.	1912.	1911.	1912.
Jan. ....	12.29	14.09	July .....	12.47
Feb. ....	12.26	14.08	Aug. ....	12.41
Mch. ....	12.14	14.68	Sept. ....	12.20
Apr. ....	12.02	15.74	Oct. ....	12.19
May ....	11.99	16.03	Nov. ....	12.61
June ....	12.39	17.23	Dec. ....	13.55

## COPPER SURPLUS

Figures showing the visible supply of copper at the beginning of each month are now widely available. Below are given the amounts, in pounds, known to be available at the first of each of certain months.

	U. S.	European.
January 1911.....	122,030,195	230,264,280
January 1912.....	89,454,695	178,329,920
February ".....	66,280,643	153,820,800
March ".....	62,939,988	141,125,680
April ".....	62,367,557	137,806,000
May ".....	65,295,368	134,176,000
June ".....	49,615,643	117,801,600
July ".....	44,335,004	107,817,920
August ".....	50,281,280	113,285,760
September ".....	46,701,376	112,743,680
October ".....	63,065,587	107,396,800

## UNITED STATES PRODUCTION AND CONSUMPTION

(Compiled from reports of the Copper Producers' Association)

	Production.	Domestic deliveries.	Exports.
September .....	115,588,950	57,311,584	50,824,011
October .....	118,255,442	64,068,656	60,084,349
November .....	111,876,601	68,039,776	67,049,279
December .....	122,896,697	65,988,474	79,238,716

Total for 1911....	1,431,938,338	709,611,945	754,932,733
January 1912 .....	119,337,753	62,343,901	80,167,904
February .....	116,035,809	56,228,368	63,148,096
March .....	125,694,601	67,847,556	58,779,566
April .....	125,694,001	69,513,846	53,252,326
May .....	126,737,836	72,702,237	69,485,945
June .....	122,315,240	66,146,229	61,449,650
July .....	137,161,920	71,093,120	60,121,600
August .....	145,628,521	78,722,418	70,485,150
September .....	140,089,819	63,460,810	60,264,796

## LEAD

Lead is quoted ordinarily in cents per pound or dollars per hundred pounds delivered at St. Louis or New York. The difference is normally 15c. per hundred pounds, and any larger or smaller difference is promptly met by sales. The daily price in New York is published each week in this column. Below are the average quotations by months:

	1911.	1912.		1911.	1912.
Jan. ....	4.48	4.43	July .....	4.50	4.71
Feb. ....	4.44	4.03	Aug. ....	4.50	4.54
Mch. ....	4.39	4.07	Sept. ....	4.48	5.00
Apr. ....	4.41	4.20	Oct. ....	4.27	5.08
May ....	4.37	4.20	Nov. ....	4.30	....
June ....	4.34	4.40	Dec. ....	4.45	....

## ZINC

Zinc is quoted as spelter, standard Western brands, and based upon St. Louis or New York delivery. While New York quotations, as a matter of convenience, are commonly used, relatively little spelter actually goes to or comes from New York. The bulk is shipped direct from the plants in the Mississippi Valley to manufacturers, due allowance being made for freight. New York daily quotations are published in this column each week. Below are given averages by months:

	1911.	1912.		1911.	1912.
Jan. ....	5.45	6.42	July .....	5.70	7.12
Feb. ....	5.52	6.50	Aug. ....	5.95	6.96
Mch. ....	5.56	6.57	Sept. ....	5.86	7.45
Apr. ....	5.40	6.63	Oct. ....	6.10	7.36
May ....	5.35	6.68	Nov. ....	6.38	....
June ....	5.50	6.88	Dec. ....	6.30	....

Zinc-dust is quoted separately, the price being based upon the cost of spelter in Illinois and the cost of preparation. About half the zinc-dust used in the United States is imported through San Francisco. Delivery prices are determined largely by quantities and contracts.

## QUICKSILVER

The primary market for quicksilver is San Francisco, California, being the largest producer. The price is fixed in the open market, and, as quoted weekly in this column, is that at which moderate quantities are sold. Buyers by the carload can usually obtain a slight reduction, and those wanting but a flask or two must expect to pay a slightly higher price. Average monthly quotations, in dollars, per flask of 75 lb., are given below:

	1911.	1912.		1911.	1912.
Jan. ....	44.60	43.75	July .....	48.00	43.00
Feb. ....	48.40	46.00	Aug. ....	50.00	42.50
Mch. ....	52.50	46.00	Sept. ....	47.50	42.12
Apr. ....	50.90	42.25	Oct. ....	46.12	41.50
May ....	46.50	41.75	Nov. ....	45.50	....
June ....	46.50	41.30	Dec. ....	44.50	....

## TIN

New York prices control in the American market for tin, since the metal is almost entirely imported. San Francisco quotations, averaging about 5c. per lb. higher than New York, are quoted weekly in this column. Below are given average monthly New York quotations in cents per pound:

	1911.	1912.		1911.	1912.
Jan. ....	41.25	42.53	July .....	42.40	44.25
Feb. ....	41.61	42.96	Aug. ....	43.32	45.80
Mch. ....	40.16	42.58	Sept. ....	39.75	48.64
Apr. ....	42.18	43.92	Oct. ....	41.18	50.01
May ....	43.11	46.05	Nov. ....	43.12	....
June ....	44.61	45.76	Dec. ....	44.65	....

## Current Prices for Chemicals

(Corrected monthly by Braun-Knecht-Heimann Co.)

Prices quoted are for ordinary quantities in packages as specified. For round lots lower prices may be expected. While in smaller quantities advanced prices are ordinarily charged. Prices named are subject to fluctuation. Other conditions govern Mexican and foreign business.

	Min.	Max.
Acid, sulphuric, com'l, 66°, drums, 100 lb. ....	\$0.75	\$1.00

## Book Reviews

Any of the books noticed in this column are for sale by, or can be procured from, the MINING AND SCIENTIFIC PRESS.

**MANUAL FOR ENGINEERS.** By C. E. Ferris. 169 pp., index. University of Tennessee Press, Knoxville, 1912. For sale by the University of Tennessee, Knoxville, Tenn. Price 50 cents.

This is a handy little volume of vest-pocket size, useful for students and engineers, and contains memoranda frequently needed. In securing matter for the book, manufacturers' handbooks, books for engineers from the publication of the University professors, and other sources have been drawn upon. The presswork and binding are exceptionally good.

**ELEMENTS OF DRAWING.** By G. E. Blessing and L. A. Darling. 193 pp.; ill. John Wiley & Sons, New York, 1912. For sale by the *Mining and Scientific Press*. Price \$1.50.

The purpose of this book is to present a course of instruction in mechanical drawing for beginners who intend to pursue a course in engineering or who desire to prepare themselves for commercial drafting. The authors, who were formerly members of the faculty of Sibley College, Cornell University, have written along the lines developed in their teaching experience. In accordance with the title, much of the matter is quite elementary, but the general arrangement for beginners is good.

**DANA'S MANUAL OF MINERALOGY.** By W. E. Ford. 460 pp.; ill., index. John Wiley & Sons, New York, 1912. For sale by the *Mining and Scientific Press*. Price \$2 net.

This, the thirteenth edition of a standard work on mineralogy, has been entirely revised and rewritten, the previous revision having been published in 1887. The scope and character are nearly the same, though the text and figures are new, and are intended to supply the needs of students, mining men, and other interested in the subject. The chapter on petrography has properly been omitted. So many good textbooks of mineralogy are now available that the revised edition of this work has not the importance of the original publication, but is likely to enjoy deserved popularity. The convenient size of the book and the excellent half-tones with which it is illustrated add not a little to its attractiveness.

**QUALITATIVE CHEMICAL ANALYSIS.** By Julius Stieglitz. Part I, Theoretical, 308 pp. Part II, Laboratory Manual, 148 pp. The Century Co., New York, 1911. For sale by the *Mining and Scientific Press*. Price: Part I, \$1.40 net; Part II, \$1.20 net.

Within the past few decades chemistry has advanced tremendously as a science from the general acceptance of the new viewpoints developed by advanced workers in the science. But these have been curiously slow in finding their way into the elementary text-books of chemistry, so that the work of beginners in high school and college was ill adjusted to the later work in the university. It is possible that Professor Stieglitz has set the plane of his instruction above the head of the ordinary student, but this is at least open to doubt. There is no more apparent reason for the student to begin his study of chemistry with faulty concepts than that a young architect should begin to build houses with material rejected from first-class work. The value to the student of the inspiration conveyed by books of this type can scarcely be overestimated, and is calculated to develop a thinking chemist rather than an automatic analyst. Its publication in two parts is a convenience, for many practising chemists will doubtless welcome the opportunity thus afforded to enlarge their knowledge of chemical theory. The Century Company is also to be complimented on securing for its initial chemical publication a book of the highest class.

## Concentrates

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

**POWER** required for a Wilfley table averages three-quarters horse-power.

**CYANIDE** precipitates of silver accounted for \$337,081 of the \$430,085 declared exports to the United States, through the American consular agency at Amapala, Honduras, in the first half of the current year.

**'SHOOTING off the solid,'** that is, blasting down coal without having undercut it, is bad practice. Heavy charges of powder produce an unnecessary quantity of fine coal and make the lump coal friable; also they weaken the roof and supporting pillars, and failure to undercut or shear the coal causes the danger of windy shots, the cause of frequent dust explosions.

**MOLYBDENITE** prices vary with its purity. In August of the current year the pure metal used in the manufacture of hard steel was selling in Germany for \$8.11 per pound. The metal which is from 99 to 99.5% free from carbonic acid sells at \$2.38, and that which is 90 to 95% free at \$1.62 per pound. There is a special kind of molybdenite, prepared by an electric process, which brings as high as \$41.90 per pound.

**PITTSBURG** consumes more coal, and more is shipped to and through the district than any other in the world. Besides using 16,500,000 short tons of coal in 1911, Pittsburgh used several million tons of coke and considerable quantities of natural gas. Greater New York consumed about 19,000,000 tons of coal last year, and its coal traffic was about 36,000,000 tons. Pittsburgh's coal traffic by rail and water amounted to 53,000,000 tons.

**POTASH** deposits can be located under the provisions of the law governing other saline deposits and springs, which states: "That all unoccupied public lands of the United States containing salt springs, or deposits of salt in any form, and chiefly valuable therefor, are hereby declared to be subject to location and purchase under the provisions of the law relating to placer-mining claims: Provided, That the same person shall not locate or enter more than one claim hereunder."

**NATURAL GAS** amounting to 508,353,241,000 cu. ft., and valued at \$74,000,000, was produced in the United States in 1911 from 28,428 wells. The increase in demand for natural gas from consumers of all kinds makes the supply a matter of concern. The gas that can be furnished in many of the fields of the United States is simply a function of the capital invested in pipes and power-plants for pumping the gas, but the safety of such large investments decreases in proportion as the unsatisfied demand becomes indicative of a failing supply.

**ELECTRIC** furnace steel was produced during the past three years with the following tonnage:

	1909.	1910.	1911.
Germany .....	17,773	36,188	66,654
United States .....	13,762	52,141	29,105
Austria-Hungary .....	9,046	20,028	22,867
France .....	6,456	11,759	13,850
Total .....	47,039	120,116	126,476

England had hardly commenced to produce for the general market. The lead of Germany and drop of the United States are notable. France makes more ferro-alloys than the others, producing 60,200 tons in 1910, of which 23,800 tons was made in electric furnaces.

## EDITORIAL

THROUGH an inadvertence the initials of Mr. A. E. Wheeler were last week given in our editorial columns as H. A.; a slip the more embarrassing since we number the able superintendent of the Great Falls smelting plant of the Anaconda Copper Mining Company among our good friends.

LEGISLATION proposed by the Colonial Court of Policy of British Guiana is peculiar in providing that only British capital may engage in the development of the petroleum resources of the colony. Money exhibits no racial characteristics, and is usually welcomed, whatever the source of origin.

STATEMENT that twelve independent steel corporations have a total capitalization of \$552,000,000 and annual output of 9,800,000 tons, or one-third of the capitalization of the United States Steel Corporation and two-thirds of its output, indicates one of the characteristics of 'big business' and causes of high prices.

WORK on the Panama canal is rapidly nearing completion. It was reported on October 1 that the construction of the Gatun dam and locks was 93 per cent finished, while the excavation work in the central division is 92 per cent completed. Money order sales at the post-offices of the Canal Zone during September amounted to nearly \$400,000 and over \$100,000 was deposited to postal savings accounts, thus indicating that the canal workmen are frugal as well as efficient.

DECISION of the Supreme Court of the United States sustaining the patents of the Moore Filter Company, granting a judgment for infringement against the Butters Patent Vacuum Filter Company, and enjoining all infringers of the Moore patents finally ends a protracted legal controversy. It is truly unfortunate that the efforts of two men who have done so much for the development of the gold mining industry have been hampered by protracted disputes as to the validity of patents. It is certainly anomalous that a non-technical court is required to decide whether the rulings of the source of technical authority, the Patent Office, are right or wrong. Why not determine the validity of patents before issuance?

CONFERENCE of mine owners and state officials in Arizona upon a proper and reasonable basis of taxation of mines is expected to result in the preparation of a bill to be submitted to the Tax Commission for introduction at the next session of the legislature. Taxation of the mining industry is often heavy, and in California mining corporations are obliged to pay a county tax, state franchise tax, state license tax, and a Federal corporation profit tax, which, together with the necessary insurance, often amounts to as much as 7 per cent of the assessed valuation. This is a heavy burden, and though mining companies are not desirous of avoiding their just contribution to the cost of government, it is only fair that the problem should be studied with care to ascertain whether they are not now obliged to contribute more than their share.

**E**VEN the dredging industry has its by-products. A contract has been let by the State Highway Commission of California for 500,000 tons of crushed cobbles to be used in highway construction, and the demand for this material to be used in county and municipal paving and for concrete work is so large and persistent as to make its production a not inconsiderable factor in the profits to be derived from gold dredging operations.

**U**NUSUAL interest is being taken in the annual meeting of the Doe Run and St. Joseph Lead companies, held at Bonne Terre today, because of a bitter attack upon the existing management made by Robert Holmes and others of St. Louis. These companies have long been in control of the Jones, Camp, and Parson families, descendants of the men who found and developed the mines. As capitalization has increased, the ownership has become divided, until now a large minority, if not actual majority, is in the hands of outsiders, including many St. Louis people. The mines have practically been operated as family affairs, paying regular 6 per cent dividends until last year, when Doe Run borrowed \$2,000,000, and cut the dividend rate to 3 per cent, to provide for the bonds. Mr. Holmes alleges gross extravagance in the executive offices, and the payment of large salaries to men in New York who contribute nothing to the success of the property, but who inherited their jobs. The technical work is not criticized, except that the continued operation of the Doe Run No. 1 mill is shown to result only in waste and expense. The mill has recently been closed. In his report to the Doe Run stockholders, Mr. D. A. Jones, the president, shows that the company since its organization in 1886 has increased its holdings from 100 to 7057 acres, and the two companies, together with the Mississippi River and Bonne Terre Railroad, have a gross capitalization of nearly \$35,000,000. In the past year 932,220 tons of ore has been hoisted, yielding 53,080 tons of concentrate and 33,729 of metallic lead, worth \$2,267,155. All expenses, including operation and interest, amounted to \$1,687,167. The approximate net profit was \$576,988. A 3 per cent dividend was paid, and bonds to the amount of \$203,000 were retired. It is estimated that next year, due to economies and enlargement of No. 3 mill, the net income will be doubled. The technical work is under direction of Mr. O. M. Bilharz.

**E**LECTION of Mr. Woodrow Wilson to the presidency is likely to meet the approval of that large body of American citizens who incline to believe that whatever party may be in power the country will not go, as Mr. Mantalini said, to the 'demnition bow-wows.' The large vote polled by the Progressive party will be of great effect in influencing legislation during the succeeding four years, and it is not improbable that a Democratic president of broad vision and progressive tendencies may be able to evoke from a Democratic Congress as much or more of useful legislation as the more vigorous Mr. Roosevelt could extract from a rebellious House and refractory Senate. Though the Democratic party theoretically opposes the whole doctrine of protection, it is not likely that any change more severe than a wholesale downward revision of the schedule will be attempted, for even slight reduction of duties causes many pinches in the business world, and the dissatisfaction arising from the necessary readjustment usually leads to a change of administration. The disappointed Republican and Progressive leaders can therefore look forward to an excellent chance to win in 1916, with the troublesome tariff removed from the field, and other collateral questions, such as the direct primary and woman suffrage, more nearly settled than at present. Business has been good previous to the election, and is now likely

to be better. To the impartial observer, perhaps the two most significant features of the contest were the personality of Mr. Wilson and the support of the Progressive party. It is a credit to American politics that a man of the character of the Democratic nominee could seek and secure election. A man of quiet and scholarly tastes, a distinguished teacher of history and political economy, and a successful executive in academic and political work, he is the type of man whose absence from the field of practical politics is most frequently lamented. Even more significant was the number of men prominent in the world of business who actively supported a platform calling for increased compensation and better safeguards for the laborer and a closer regulation of the activities of large aggregations of capital. Support of such a platform by such men could only result from a conviction that the right line of progress lies in that direction and the sooner 'big business' gets into line with true progress the more it will prosper.

### Utilization of Power

Not the least of the many valuable features of the important discussion by Mr. E. P. Mathewson of the development of the reverberatory furnace in copper smelting, which we reprint elsewhere in this issue, is his record of the interesting and suggestive results obtained from the use of wood gas producers at Kyshtim, Russia. The low power cost there obtained is, of course, largely due to the low cost of wood, but the achievement of a fuel cost of 33.6 cents per ton smelted, even under favorable conditions, is a notable example of what can be done in an isolated power-plant. Mr. M. W. von Bernewitz also describes the use of gas-producers and gas-engines at the Waihi mine in New Zealand, where the cost of power was reduced to less than two-thirds of that with the steam-plant formerly employed. It is safe to say that the development of the utilization of power in the mining and metallurgical industry has been somewhat neglected, largely because the rapid progress in the generation and transmission of hydro-electric power has enabled many plants to change instantly from the old low-efficiency steam-boiler and slide-valve engine to the highly efficient electric motor. This is admirable, so far as it goes, but hydro-electric power is not everywhere available and the operator in districts where it is not, profits nothing from its economies in more favored districts. The early stages in the development of the gas-producer excited great general interest and no less general disappointment when it became definitely known that the cost of construction and the difficulties of operation upon a small scale render it unavailable for plants of small or moderate size, though highly efficient in large installations. More recently great improvements have been made in the construction of producers and engines of small size, especially the oil-gas producer, while the development of internal-combustion engines of the Diesel and other types is perhaps the most important event in the mechanical world of today. Neglect of the unit power cost by the small consumer is not unnatural, since it forms only a small part of the total operating cost, and the manager finds it necessary to devote his attention to the control of operating items which greatly exceed it in influence on the total. In addition, low-efficiency types of machinery are often employed in order to minimize capital expenditure in the early stages of an enterprise, and the assured saving to be effected by more efficient types is not always sufficient to justify the cost of installation. On the other hand, the increased capital cost of the more efficient type is often small enough so that, depending on the outlook for success in the enterprise, it is better business to employ the more expensive type from the beginning. The increasing demand for

high-efficiency machinery for power development and utilization upon a small scale is stimulating manufacturers to supply the equipment needed, while, on the other hand, the operator has begun to learn what can be done to supply his needs, and to lay his plans accordingly. Now that the mining and metallurgical industries are changing from the high cost and large profit condition of the early days, to moderate profits won by careful planning and skilful operation, it is to be expected that power-plant practice will exhibit a corresponding degree of advancement.

### Europe and the Balkan War

The busy engineer, having paid but little attention to the historical development of modern Europe because of more imminent matters, such as the stopping of frothing in his cyanide vats or the prevention of 'camming' in his stamp-mill, to absorb his mental energies, is likely to share the attitude of little Peterkin and inquire, "what good will come of it at last?" as he reads of the series of victories which the allied Balkan armies have gained over the Turkish forces. Any more illuminating answer than the inquisitive child received is difficult to make, but the possibility of these battles having a direct influence upon world policies of powerful nations, and consequently upon the citizens of every country, is sufficiently great to make a brief summary of the history of the vexatious Near Eastern question of interest and importance to the cosmopolitan mining engineer.

The Balkan peninsula is a mountainous area lying south of the Danube and Save rivers and is washed on its southern margin by the Ionian, Mediterranean, Egean, Marmora, and Black seas. With a total area, including adjacent islands, of about 150,000 square miles, or approximately the same as the state of Montana, it contains within its borders the sultanate of European Turkey, the czarism of Bulgaria, Eastern Rumelia, the kingdoms of Greece, Serbia, and Montenegro, and the Austrian provinces of Bosnia and Herzegovina. The peninsula has been a seat of civilization since an early period and the Macedonian Empire under Alexander as well as the subsequent intellectual empire of Greece dominated the world of their time. Later a part of the Roman Empire, its inhabitants became converted to Christianity in the time of the Christian emperors. In the time of Diocletian, the Roman Empire was, for administrative purposes, divided into two parts, of which the Balkan peninsula formed the eastern division. When the western empire of Rome was overthrown by the Gauls in 476 the eastern division continued its troubled existence for a thousand years, until in 1453 the Ottoman Turks under Mohammed II swept across the Bosphorus and conquered the whole peninsula. Suleiman I extended his dominion over Hungary, and even, in 1529, besieged Vienna, but his successors were less vigorous and his death marks the beginning of the decline in power which has ever since been characteristic of Turkey. That peaceful conditions in the peninsula could never be attained under Turkish rule was evident from the beginning. With Christian races of the lineage of ancient Greece and Macedonia, governed by corrupt and venial Mohammedan officials and with fanatical religious antagonism superimposed on political injustice, continual unrest is sure to be the result. As Turkish power waned the unrest of its Christian subjects increased until, by the beginning of the nineteenth century they were ready to successfully assert themselves. In 1820 the Greeks revolted and after a ten years war their independence was recognized by the Porte. Meanwhile Russia had declared war upon Turkey, and in both these conflicts the most potent and significant factor was

the concerted action of the great European powers. Following the treaty of Chaumont in 1814, and the subsequent Congress of Vienna and fostered by the influence of Prince Metternich, the European nations had come to act together to maintain the equilibrium of power throughout the continent. The effects of this 'political trust,' as it may be called in the language of the day, are perhaps most clearly seen in the maintenance of Turkish sovereignty in the face of conditions which would normally have led to its overthrow. Every European power is interested to prevent Turkey from being overthrown because each is unwilling to have any of the others obtain possession of the Balkan peninsula. Russia has coveted it since the time of Peter the Great, for that enormous empire urgently needs for its development better seaports than those on the ice-bound Neva and Amur and at Vladivostok. England no less urgently strives to check the Russian advance toward the borders of India. Domination of the eastern Mediterranean by a Russian fleet, with the possibility of a blockade of the Suez canal is as undesirable to England as the opportunity for naval and maritime progress is essential for Russia. Austria would also be glad to secure the Balkan peninsula, while Germany, France, and Italy, for commercial and strategic reasons are as anxious to prevent it. Nevertheless, in the words of Mr. C. M. Andrews, referring to the treaty which terminated the Crimean war, "the maintenance of the integrity and independence of the Ottoman Empire \* \* \* was probably the most ill-advised and suicidal diplomatic action that has ever been taken by a body of representatives discussing international questions. To guarantee the integrity of a state that for two centuries had been suffering steady but certain dismemberment, was to ignore the lessons of the past, to invite war, and to insure anxiety for the future. \* \* \* The Mohammedans refused to be associated with the despised infidels in administration and to obey them in places of authority, either in the state or army. The Christians preferred to pay tax rather than serve in the army and were afraid to take their places in the tribunals or to hold positions of prominence." Various attempts at reform proved futile, and in succession the people of Rumania, Serbia, and Montenegro rose in revolt and, as a sequel to the Russo-Turkish war in 1877, achieved independence. Bosnia and Herzegovina were placed under the sovereignty of Austria, and Eastern Rumelia was made autonomous under a Christian governor-general, nominated by the Sultan. The quarrels between Mohammedans and Christians have continued unabated, and the Balkan states have been in continual unrest through difficulties with each other and from their concern in the oppression suffered by their compatriots who still remain under Turkish sovereignty. The war now in progress is the outcome of the measures taken by Turkey during the past year in suppressing a revolution on the borders of Montenegro. The King of that tiny country, which has an area of 3600 square miles and a population less than that of San Francisco, courageously declared war, in which Greece, Serbia, and Bulgaria hastened to join. In three weeks vigorous fighting the allies have pushed the Turks back to the outskirts of Constantinople and the Turkish Government has requested the intervention of the great European nations to prevent its complete overthrow. Austria and Italy are disposed to intervene, but England, France, Germany, and Russia seem disposed to give the allies a free hand, for the present at least. What will be the final outcome only the event will tell. If the varying interests of the great European powers can be so reconciled as to permit the expulsion of the Turks from Europe, lasting peace may come after three centuries of turmoil. If not, there will follow a new buttressing of Turkish power in order to postpone a little longer its inevitable fall.

# Cyanide Plant at the Empire Mines, Grass Valley

By FRANK A. VESTAL

This plant was started on December 1, 1910, and has since been in continuous operation, treating the tailing and concentrate from a 40-stamp mill, together with the concentrate purchased from the Pennsylvania Mines Syndicate. The stamps used weigh 1050 lb. each, crushing approximately  $3\frac{1}{2}$  tons per stamp per day through a 35-mesh slotted screen. Both inside and outside amalgamation are used, 90% extraction being obtained.

From the plates the pulp passes over sixteen 6-ft. Frue vanners, which remove from two to three tons of concentrate per day. The tailing goes directly to the cyanide plant, while the concentrate is re-ground in a 4 by 8-ft. Allis-Chalmers tube-mill. The concentrate is shoveled into an 8-ft. receiving box of one ton capacity, which rests just above the mouth of the tube-mill at an angle of  $6^\circ$ . After passing through the tube-mill the product is raised by a water ejector to a Merrill concentrating cone, the overflow passing over two amalgamated plates 2 by 5 ft., where from 15 to 20% is saved. The oversize drops into a long receiving launder. This launder is movable, being attached to an 8-ft. screw shaft by means of a two-piece nut.

EMPIRE CYANIDE PLANT, GRASS VALLEY.

The shaft is geared so as to move the launder 8 ft., the length of the receiving box, in 6 hours. The discharge end of the launder is started over the lower end of the receiving box, and the underflow from the cone washes the concentrate into the tube-mill at the rate of one ton in six hours.

The tube-mill is run continuously, handling about 4 tons in 24 hours, 85% of which passes a 200-mesh screen. The value of the concentrate is from \$60 to \$115 per ton. Much better work is being done in the leaching plant since the Pennsylvania concentrate has been added, as the tube-mill was not before run continuously and the concentrate formed in layers in the sand-vats, making the sampling of the residue very uncertain. The tailing from the vanners is conveyed to the cyanide plant through a 16-in. terra cotta pipe. After 18 months continuous use this pipe shows little or no wear. The concentrate, after leaving the tube-mill plates, is conveyed to the regular tailing launder in a 2-in. galvanized iron pipe.

The mill tailing is 46% fine and 54% coarse. The entire discharge runs to a distributing sump, which in turn feeds to two Merrill settling cones, the overflow from these cones passing to four clarifiers or de-waterers, the underflow passing to four Merrill hydraulic sizing-cones. The overflow from these cones passes to the clarifying tanks, while the underflow goes to the sand-vats. The settling-cones are fitted with interchangeable nozzles, by means of which the overflow can be regulated as to amount and fineness. The sizing cones are fitted in the same way, but in addition water is introduced through a special casting at the bottom. This gives a decidedly flexible classifier, almost any product being obtainable either as sand or slime.

The slime runs to a central distributing sump fitted with slide gates, which permits a varying amount being sent to any clarifier. These clarifiers are 22 ft. deep and 24 ft. in diameter, built with a false conical bottom. The centre cylinders in the clarifiers were originally  $10\frac{1}{2}$  ft. long, but on experimenting it was found that a cylinder  $6\frac{1}{2}$  or 7 ft. long would cause no agitation on the surface and give more settling room when forced to shut down any part of the slime department for repairs, and still maintain a clear overflow.

The discharge is in the centre of the bottom, the pipe running to the side of the tank and rising 9 ft., allowing the slime to run to the Pachuca tanks by gravity. The discharge pipes are fitted with interchangeable Merrill nozzles, and any density of pulp is obtainable. At present pulp from 1.4 to 1.6 gravity is in use. There are four Pachuca tanks, 10 by 18 ft., run in series. The pulp is run into Pachuca No. 1, dropping into a 12-in. cylinder 8 ft. long; this is used to force the pulp to make at least one circuit before any part of it runs over into Pachuca No. 2. This Pachuca is fitted up in the regular way with the centre cylinder 10 in. from the bottom of the tank and a few inches above the level of the pulp. The discharge is about 4 ft. from the top of the tank and enters Pachuca No. 2, 10 ft. from the top, No. 2, 3, and 4 Pachuca being piped in the same way.

In No. 2 Pachuca the cylinder is only 8 ft. long, being submerged at all times. A baffle-board is fixed about 1 ft. from the top of the cylinder, the idea being to break up any possible heavy slime and to help in mixing. No. 3 Pachuca is arranged in the same way, with the exception of the cylinder, which is 12 ft. long. No. 4 Pachuca contains no central cylinder at all, being merely a tank with a false conical bottom. The pulp is fed directly to the filter-boxes from the No. 4 Pachuca.

Both cyanide and lime, dissolved with barren solution, are added to Pachuca No. 1 to get the necessary strength. Barren solution is also added to No. 2 and No. 3 Pachuca to bring the pulp to the consistence best suited to the filters. This solution, being added to No. 2 and No. 3 Pachuca, freshens up the charge and gives better results than when all added at No. 1. Sufficient lime and cyanide are added to keep effluent solution from filters at a strength of 0.04% KCN and a sufficient degree of protective alkalinity.

The cyanide consumption ranges from 0.75 to 0.90 lb. per ton of ore. Several experiments were made with solutions ranging from 0.04 to 0.12%, but the extraction was no better, while the cyanide consumption increased almost at the same rate as the amount of cyanide added. In other words, using a 0.12% solution, the consumption reached 0.09%, or 1.8 pounds.

The pulp passes to two 35-ton Oliver continuous filters. The gravity is kept between 1.3 and 1.35.

An Oliver wet-vacuum pump is used, maintaining a vacuum of 22 in. The filters are fitted with a front and back wash, being piped so as to permit either barren solution or water being added either in front or back or both. When the filters were installed it was thought that a front wash would be all that was necessary for this particular product. Some experiments made may be of interest.

Before the concentrate was added, the slime-heads averaged in precious-metal content as follows:

January, heads \$1.81, residue 24c.; April, heads \$1.99, residue, 25c.; February, heads \$2.03, residue, 30c. This shows the residues without a back wash.

May, heads \$1.95, residue 14c.; June, heads \$2.11, residue, 15c.; July, heads \$1.65, residue 11c. With both front and back wash.

After the sulphides were added the gold content in-

creased as follows: August, heads \$2.38, residue 17c.; September, heads \$2.89, residue 22c.; November, heads \$2.60, residue 20c. With both front and back wash.

On a 2-hr. test made without a back wash the residue content reached as high as 40c. per ton. The filters, making a revolution in 8 minutes, allow  $1\frac{1}{4}$  min. for washing with a front wash. With the added back wash a period of  $2\frac{3}{4}$  min. is obtainable. The former time is more than doubled because on the front side of the filter one compartment (or  $1/24$  of the filtering surface) is discharging the cake, while at the back side that one compartment is gained for washing.

To prevent the excess water or barren solution added

first few days, but later it began to curl up and during the cold weather would freeze. Another objection was that when the power would go off, or a shut-down occur, on starting up the filters the vacuum would tear the rubber from the launder. Next a sheet-iron launder (No. 20 iron being used) was made with one side 15 in. high and the other 3 in. The high side is bent to meet the contour of the filter, with the upper edge flattened out so as to only leave a bearing surface of  $\frac{1}{2}$  in. The overbalancing of the launder against the filter holds it in place. Up to the present time this launder has given entire satisfaction. In 24 hours hardly enough fine slime is washed away for an assay, and the excess water only carries a trace of gold.

at the back of the filter from running down into the filter-box and diluting the solution and thinning the pulp, a launder was constructed to catch this excess. In the first experiment a heavy piece of rubber belting formed in the shape of a U-launder and supported by a strip of wood across the filter-box, was set at an angle, the excess wash running to waste at the lower end. This was not satisfactory, mainly because a thick belt was necessary for strength, and as a result the water would strike the edge of the belt and be carried to one edge of the filter and deposited in the filter-box. Next a wooden V-shaped launder was built and a strip of rubber 1 ft. wide by  $1/32$  in. thick was tacked to the side of the launder. This rubber was allowed to rest against the cake for practically two-thirds of its width. This caught nearly all the excess for the

The filters are doing good work and require little attention, only one man being required to run the entire plant on the two night shifts. A cake from  $3/16$  to  $5/16$  in. is formed. The slime is practically free from granular particles, and is exceedingly sticky and impervious. The scraper for removing the discharge cake must be filed at least twice a week, taking one man about 15 minutes for each. When properly taken care of, the life of the canvas is from five to six months. The Pachuca tanks are run in series and several samples taken at different times between the tanks showed a uniform extraction, proving that very little, if any, slime made the circuit before being attacked by the solutions.

There are four sand-vats of 155 tons capacity each, fitted with inside overflow-launder. The sand is carried by

means of an overhead launder to each vat and distributed by a Merrill distributor. During the filling, lime is added to the charge, about 2 lb. per ton of ore being used. After filling, the charge is allowed to drain for 5 hr., the top being raked and leveled and 100 lb. of slaked lime added. After a vat has been filling for 12 hr. the drain valve is opened, which, in decreasing the overflow, lessens the chances of losing gold in this way. The gold being mostly in the fine, makes this necessary. Several samples were taken of the overflow water, the amount of solids being weighed and assayed, and it was found that from  $\frac{1}{6}$  to  $\frac{1}{4}$  ton was being lost every 24 hr. This assayed \$2 per ton, a maximum loss of 50c. per day. As an experiment an inner rim 12 in. high was placed inside of the regular overflow edge of a vat, this rim resting 1 in. higher than the top of the vat, and being held away from the inside of the regular overflow by small blocks  $\frac{1}{2}$  in. thick; the idea was to get away from the waves caused by the distributor and to force the overflow to go down under the inside rim. A much more even overflow was thus obtained, but several samples taken showed little, if any, saving over the old method.

The product in the sand charges is  $87\frac{1}{2}\%$  coarse, against  $12\frac{1}{2}\%$  fine. After the 5-hr. drain period, a 0.10% solution is added to the top of the charge, 40 tons in all being used. The solution coming from the vats is allowed to go to waste until it shows a trace of KCN, when it is turned into the gold sump. After a KCN strength of 0.04% has been reached, the content is the highest. At this time the effluent valve is closed and the charge is allowed to stand for 10 hr.; the idea is to give less solution tonnage and at the same time enrich the solutions. The effluent solution from the filter is added as a second solution, but it is absolutely necessary to clarify the filter-solution before precipitation takes place, and the sand-vats are used for this purpose even after the extraction has been completed. A small clarifying tank as well as an excelsior filter is used in the event that the sand-vats cannot handle the filter output, which amounts to 144 tons per 24 hr. Either barren solution or water is used for the final wash, about 70 tons being necessary.

Each vat is fitted with a Merrill centre gate and has a sloping bottom to facilitate sluicing. The vat itself is built in the regular way, but the false-bottom is 8 in. high at the outside against 2 in. at the centre gate. An automatic sluicing machine is used for discharging the vats. This is similar in construction to a lawn sprinkler, hanging from an overhead track. This type of machine was first used, I believe, by E. L. Oliver at the North Star mines. It works well, but plenty of water is needed. A hose is necessary for the last half-hour's sluicing for cleaning up the bottom. The weaker solutions (both in gold and KCN) are precipitated separately, and later run to waste if the assay returns are satisfactory. A great portion of this, as stated before, is used as a wash on the filter or sand-vats, or for thinning the pulp in the Pacluea tanks.

The well known Merrill zinc-dust precipitation is used. Two 125-ton presses, with ten 36-in. frames, handle the total solution tonnage for the month. The zinc-dust is uniformly distributed along a rubber-belt conveyor of the same length as the depth of the tank. The belt is operated by means of a large float which, sinking with fall of the solution being pumped, moves the belt at the proper speed. The zinc falls into a receiving-cone, where barren solution is added, an overflow pipe carrying the zinc emulsion to the suction pipe of the pump. A mechanical agitator is used in the cone in preference to air. The air tended to oxidize the zinc and at times gave more or less trouble with precipitation. In my opinion the belt feeder arrangement gives more uniform speed than any other feed if properly taken care of. The zinc consumption amounts to about 0.19 lb. per ton of ore. Consumption per ton of solution has averaged as low as 0.12 lb.; at times 0.10 lb. of zinc per ton of solution has been used, giving 1c. barren solution. The

weak solution is kept at a strength of not less than 0.03% KCN. A less amount of zinc is added to the higher-grade solution, as it is standardized and used as strong solution. Using less zinc gives a higher-grade precipitate and makes a saving in several ways, while 4c. or 5c. barren solutions are of no importance when the solution is saved.

More or less trouble was encountered during December and January. At first it was thought that the cold solutions were causing this, the temperature being around 36°F., but several tanks were heated, with no better results. Forty tons were pumped with temperature at 37°, and the remaining 40 tons of the same tank heated to 56°, and the results were the same, although a little more zinc was necessary with the cold solution. At this time the sand treatment was changed in such a way that the vats could not handle the filter solution, so the other small filters, for clarifying purposes, were taxed to their capacity. Apparently the pregnant solutions were perfectly clear, but on close examination were found to contain a little fine slime. On opening the presses a thin layer of slime was found at the top of each frame. On changing the treatment of the sand and cutting out the filters, good results were almost immediate. Excess zinc tended to relieve matters a little, and this led to the belief that the fine slime merely coated over a certain part of the zinc being added and also that already in the press. While our precipitation troubles have been few, they have invariably been traced to solutions not having been thoroughly clarified.

Continuous precipitation has proved more satisfactory than intermittent. The precipitate as it comes from the press is worth from \$18 to \$30 per pound. The precipitate is melted with a flux containing  $\frac{1}{2}$  of borax to 1 of dry precipitate, 20% soda, and 2% silica, which gives the best results. One No. 40 and one No. 120 Steele-Harvey tilting furnace is used, with crude oil as fuel. Originally the precipitate was dried to just before the dusting point, and then screened and fluxed; at present it is not dried nor screened, but is fluxed and melted direct from the presses. In January one-half the total product, which contained 49% moisture, was fluxed and melted in less time than formerly required for melting the nearly dry product. It is necessary, of course, to feed in the precipitate fast enough to keep a crust on the top of the metal or 'spitting' will result. When pouring, the pot is emptied each time, allowing the next charge to be added at once with no chance of spitting.

The zinc fume from the furnaces was objectionable, and it became necessary to use some means of controlling it in order to protect the men. The first thing tried was a large inverted cone with a stack leading up through the roof (the building itself is fitted with a cupola for taking away the smoke), which resembled in every respect the stack on a blacksmith forge. This was not entirely satisfactory and was the cause of some dusting, the draft being very strong. A device for catching the dust was arranged in the stack of the large furnace, with the result that the greatest amount caught was 4 lb. per run, the value being \$2 per pound. At present a sheet-iron house is placed around each furnace, being built from the floor up and connected to a flue 20 in. square, which runs on a downward angle for a distance of 25 ft. At this point a T was put in, the bottom being fitted with a sliding door and acting as a dust-chamber. The upper part runs into a stack of suitable height. Doors were put in at the proper places around the furnace and glass panels arranged to the best advantage for watching the fire. This arrangement has proved very satisfactory, no trouble arising from the fume. Practically no dusting takes place, none showing at the top of the stack and little being deposited in the dust-chamber after three melts.

The slag carries more gold than if other methods of melting were used. At certain periods the slag is sacked and shipped to the smelter. Great difficulty is met in getting slag assays to check, owing to the shot. In sampling, every ninth shovelful is reserved and run through a small crusher. This product is again cut down and

crushed to a fineness of about 40 mesh. This is panned and the shot separated; the percentage of shot is recorded and assayed, the rest of the sample being reground and assayed. In this way a fair check is made on the amount that should be in the slag, using the solution and precipitate value as a check against the bullion and slag. At present experiments are being run in treating the slag in the mill grinding-pan. One hundred and fifty pounds of slag was run through a small crusher and an assay taken, showing a value of \$1 per pound. This was fed into the grinding pan and silver added in the necessary quantity. The result was 90 oz. of a mushy amalgam which retorted 30 oz. of base metal. This was in turn melted down (after adding litharge to give uniformity for sampling), and this assayed 347 fine. The results were \$215.10 from a supposed content of \$250, still leaving 14c. per pound in the slag. Assays taken from the slag residue run \$0.075 per pound. If future tests work out as well, the entire product will be treated in the same way, as the cost is small and the returns are quick.

The treatment cost per ton of ore, averaged for six months, after adding concentrate showed an increase over the preceding six months of \$0.005 to \$0.02.

#### EXTRA COST DUE TO TREATING CONCENTRATE

Lime to tube-mill, 1/2 ton.....	\$ 8.00
Extra lime to cyanide plant, 1 ton.....	16.00
Extra KCN to cyanide plant, 100 lb.....	18.90
Extra power .....	15.00
Extra pebbles .....	6.50

Total .....\$64.40

Taking the average tonnage per month makes the cost about 65c. per ton. While this seems small, a careful examination of the past 10 months' run shows this to be a just charge. An extraction of from 87 to 89% is obtained from the sand, while the extraction on the slime is 90 to 93%. Pipes are being laid direct from the tube-mill plates to the Pachuca tanks with the idea of treating all the concentrate with the slime.

The plant contains two Aldrich triplex solution pumps run by two direct-driven 3-hp. motors; one Oliver wet-vacuum pump, run by a 15-hp. belt-driven motor; two Oliver filters driven by a 7 1/2-hp. motor, belt driven; a 4-ton Allis-Chalmers tube-mill, 10-hp. motor, belt driven; and one lime-pan with a 2 1/2-hp. motor. The actual horse-power used per motor amounts to:

One solution pump .....	1.6
Compressor .....	15
Vacuum-pump .....	8
Filter .....	2
Tube-mill .....	8
Lime-pan .....	0.7

One shiftman and one helper are employed on day-shift, and one shiftman on each of the other two shifts. A foreman has charge of the cyanide, refining, and assay office, remaining on day-shift all the time. The assayer does the work for the mine, mill, and cyanide plant. The treatment cost for 1911 amounted to:

Labor .....	\$0.14
Power .....	0.035
KCN .....	0.17
Lime .....	0.03
Zinc .....	0.02
Assay .....	0.03
Refining .....	0.02

Total .....\$0.445

Henry Hansen was the metallurgist and designer of the plant and J. T. Hooper was superintendent of construction, with F. C. Languth as metallurgical engineer on the ground to put the plant in operation.

THE Simmer & Jack East Mine, Ltd., was sold at auction to the Knights Deep, Ltd., on September 26, for £250,000.

## Mine Waters

By A. C. LANE

### HISTORICAL INTRODUCTION

\*While the fact that the deeper waters around Lake Superior are peculiarly salty has been known for over twenty years, it was not known at the time of Pumpelly's study, because the mines had not reached the depth where this feature became characteristic. The first published analysis of Lake Superior mine waters, showing their salty character at depth, that I know is that of the Silver Islet mine, within sight of Isle Royale but on the Canadian side of the boundary. This analysis should, perhaps, be included geologically with the iron country waters (since the mine is in Huronian rocks), but the salt content is very heavy and the water may derive its salt content from Keweenaw intrusives.

I am told by W. W. Stockly, who at one time worked with L. G. Emerson, one of the most prominent early engineers and an assistant of R. Pumpelly during the time Pumpelly was preparing Volume I of the Geological Survey, that Mr. Emerson took samples of some salt water which came in at about sea-level at the Cliff mine. Johnson Vivian says that this water was 1800 ft. down. The plan of the mine in the Mineral Statistics report (for 1880) shows the bottom of the mine at the 220-fathom level, 1680 ft. below the top of the greenstone. It was probably taken, therefore, about 1879, but I have found no printed reference to it. The Silver Islet water, analyzed by W. M. Courtis, is described in the Canadian reports.<sup>1</sup> The analysis is also given in my papers before the Lake Superior Mining Institute.<sup>2</sup> The next analysis published and the first which called my attention to the matter was made by R. L. Packard when I was at the Michigan College of Mines.

It was not, however, until many years later that I fully realized the widespread character and the geological importance of these waters. It is obvious that if there is found included in the copper country rocks three different kinds of water distributed in fairly horizontal layers it is reasonably certain that there has been no round-and-round circulation since these waters have been thus arranged. The question as to how thorough the circulation of water in the upper levels of the earth's crust has been is one which has been much discussed of late years, particularly by Van Hise and Kemp, and papers on this subject are listed and summarized in Kemp's yearly review of the literature of ore deposits in the annual volumes of Mineral Industry. I have given some preliminary results of my own work in a series of papers.<sup>3</sup> It was natural for me to do this because I had in mind the continuation of my study of the

Soc. Amer.*, Vol. 19, pp. 501-512.

water resources of Lower Michigan by a study of the waters of the Upper Peninsula, which naturally led me to take up the study of mine waters. I shall not repeat in full the data which I have heretofore given, except where necessary to aid in the solution of the problem, but I shall summarize them and give new data. The more I looked into the matter the more I found it of geological and practical importance.

#### SUMMARY OF RESULTS

The study of these waters is of practical interest, in the first place, because the admixture with the upper waters of the lower strongly saline waters affects the use of the mine waters in boilers. The study may lead to a different plan of pumping and other handling of the mine water. In the second place it seems fairly clear that the character of the waters has had a good deal to do with the deposition of the copper. It is a curious and significant thing that one seems to find traces of similar waters high in chlorides in other districts in which native copper occurs, and it is interesting to notice that heretofore<sup>4</sup> in the discussion of ore deposits the importance of chlorides seems to have been little regarded compared with sulphates, in general.

Finally, the chemical character of these waters seems to also bring up very interesting questions as to possible changes in the chemical character of the ocean throughout geologic time and also the question whether the Keweenaw rocks were laid down in the ocean or whether these waters may not have been derived from saline pools in the deserts. It may also be said that the study of these waters has its bearing upon all the theories of chemical alteration and change of these rocks and also upon the question of the temperature and the rate of increase of temperature which will be found in depth. The facts and conclusions summarized below are those which are particularly important if true. I begin with those most firmly established and pass to others of which I am not so sure.

1. In the copper country as in the iron country the surface waters are soft as compared with those of the Mississippi Valley and generally are more like those of New England. This is true also of the actively circulating waters.

2. In the copper country, in the iron country, and in the sandstone country of the eastern part of the Upper Peninsula, below the layer of soft waters, in which there is relatively active circulation, there is a layer of water in which there is a marked amount of sodium chloride. The chlorine increases steadily, the sodium increases, and the calcium increases, too, so that it is safe to say that calcium chloride is present. Moreover, in the deeper waters calcium chloride predominates. This second or middle layer of water, however, contains sodium in greater quantity than can be imagined to have been produced by simple mixture of the surface waters in which there is a small amount of sodium carbonate and silicate with the deeper waters in which the calcium chloride dominates very largely over the sodium chloride. In other words, there is a distinct belt of sodium chloride waters.

3. Beneath the second belt will be found water extremely strong and practically saturated in many cases with calcium chloride. The ratio of calcium to chlorine becomes nearly 1 to 2. Such waters are extremely corrosive in boilers and pumps and, of course, hard.

4. In this presence of calcium chloride they resemble waters which are found in connection with similar associations of copper, trap, and red sandstone in Chile, in New Jersey, and in the Sahe-Nahe region on the west bank of the Rhine. We also find similar waters in the older rocks all over the Mississippi Valley, and, in fact, more or less all over the world. Such waters seem at least in part to have been buried with the strata now containing them and may be called connate waters.

5. Flows of these deeper or connate waters when developed in mining decrease and soon drain off, showing

that there is no open connection with the surface.

6. The exact level at which a given strength of water is found varies greatly, but below 1500 ft. it is common to find them stronger than the present sea water (sp. gr. 1.028).

7. The proportions of the different salts are very different from those in present sea water, so that it must be supposed that they are not derived from ocean water or that the ocean itself has changed in composition (which there is good reason to believe) or that these waters have also changed in composition since they were enclosed.

8. I can explain the strength of the strongest of these waters only as that of the residue left after most of the water had been absorbed in hydration of the rock.

9. The third or lowest kind of water not infrequently contains a measurable amount of copper chlorides.

10. Similar chloride solutions may be made artificially to precipitate copper very much as it occurs in the mines upon prehnite and other minerals which tend to keep a solution alkaline, if such a solution containing copper is kept unequally heated.

11. The mode of occurrence of the copper, the chemical character of the alterations of the rock, the character of the copper ore-shoots, and the low temperature-gradient are all consistent with the theory that the migration or circulation of water in the Keweenaw rocks is not mainly a mere up and down or a round and round circulation, but an absorption or imbibition of water by the strata acting like a sponge in which process of absorption of the water the copper is formed and accumulated in a zone of relatively low oxidation in which as it replaces chlorite and prehnite and other minerals which tend to keep the solution alkaline or at least not acid, it tends also to accumulate with other positive ions at the alkaline or negative (cathode) or warmer end of the solution.

12. This production of native copper may be associated with the production of ferric iron built into epidote from ferrous iron.

13. The accumulation of copper is also associated with reactions by which the calcium of the calcium chloride is replaced by sodium derived from the rocks, sodium silicate being largely removed in the process of decomposition, which accounts for the sodium of the middle zone of water.

14. When the accumulation of alkalis becomes sufficiently high, alkaline zeolites, etc., may be formed, but this is toward the end of the deposition of copper and in the upper levels, where it may be redissolved and migrate downward.

15. The ultimate source of the copper would seem to be the formation itself, effusive as well as intrusive beds in the same, together with copper possibly originally dissolved in the water. But there is some indication that the sulphur came from intrusives or fissures.

16. The general average of copper from extensive 'sludge' analyses would seem to indicate that the whole rock formation contains something like 0.02% of copper, and analyses of the stronger mine waters would indicate that copper content of the strong chloride waters may be as high as 8 to 16 mg. per litre.

In accordance with the idea above developed, that the copper forms where its chloride solution is kept alkaline by sodium silicate in other alkali dissolved from the rock, it is not surprising to find the copper present in the hanging and foot-wall of the porous bed proper, and so (if the data of experiment and physical chemistry may be used as a guide) one may expect to find the copper near pervious streaks, but in the part that was hotter,<sup>5</sup> that which was more alkaline and reducing,<sup>6</sup> and that which was electrically positive<sup>7</sup> (cathode).

<sup>5</sup>Near the less porous rock at bottom and sides in case of down circulation, at the centre of the lode in case of up circulation.

<sup>6</sup>Associated with green colors, chlorite, epidote, prehnite, rather than red laumontite, etc.

<sup>7</sup>Perhaps, therefore, also on the north side.

<sup>4</sup>A paper has recently been published by C. R. Keyes, *Economic Geology* II, p. 774.

Power at the Waihi Mine

By M. W. VON BERNEWITZ

At its Waihi and Waikino mills the Waihi Gold Mining Co., Ltd., uses water, steam, and gas power, electric power not yet having been developed to any extent, though a large hydro-electric plant, costing \$750,000, is well on toward completion. At the mine, a large gas plant was erected about two years ago to develop electric power for the mine pumps in No. 4 shaft. The surplus power is transmitted to the Waihi mill, about 1/2 mile, and a 250-hp. motor drives the tube-mills, and a 100-hp. motor drives the pumps and other machinery at the slime plant. The rainfall totals 85 in. yearly, yet after a week's dry weather the water supply diminishes rapidly. The maximum water power available is 306 hp.; the average developed for the year was 117 hp. Three main Pelton wheels of 150 hp. are in use, and one water-turbine of 100 hp. The 90 stamps crushed 111,133 tons of ore. The

regarded. Construction of the power plant is well under way, although weather conditions have hindered work. The water required by the turbines will be 4500 cu. ft. per second. The Waikato river was exceptionally low last year, and at Hora Hora 6317 cu. ft. was gauged in the summer. Steel towers will carry the transmission wires over the hills to the mine and stamp-mills. The voltage to Waikino will be 50,000, and from there to Waihi, 6 miles, stepped down to 5000, the motors taking 550, alternating current as is usual. The Waihi company has permission to sell power to other mines and towns near the transmission line.

The following table, supplied me, shows costs for power at the Victoria mill:

Gas power...	893 hp.;	average per b.hp. for year..	\$45.20
Steam .....	261	" " " "	.. 76.82
Water .....	558	" " " "	.. 4.56
	1712		\$35.84

THE movement of Lake Superior iron ore down the lakes in September amounted to 7,287,230 gross tons, as compared

GAS-ENGINES DRIVING TUBE-MILLS AT WAIHI.

main steam-engine at the Waihi mill is used continuously. It was built by Yates & Thom, of England, with cylinders 15 and 30 in. diameter and 42 in. stroke, with a full load of 400 hp. A variety of boilers is used. There is an extra engine each for the tube-mills and slime plant. During 1911 the Victoria mill, of 200 stamps, at Waikino, crushed 238,093 tons of ore. The average brake-horse-power developed by the turbines and Pelton wheels was 558. One of the 200-hp. Vortex turbines was opened and inspected after 12 years' work. An enormous quantity of tailing from the Ohinemuri river had passed through the turbine during this long run, but wear from attrition was negligible. By the steam plants 261 hp. was developed, the main Yates & Thom engine being cross-compound, 19 and 36 in. diam. by 54 in. stroke.

The gas plant at this mill is of great interest, and power cost has been cut to a minimum. New Zealand coal is used in the producers, and Crossley suction gas-engines drive the tube-mills and plant. The engines vary from 200 hp. each to the 260-hp. tandem size. During the year 893 b.hp. was developed.

As before mentioned, the Waihi company is spending \$750,000 on a hydro-electric plant at the Hora Hora falls, 51 miles from Waihi. So far, \$360,000 has been spent on the headworks and station, roads, bridges, and plant generally. Turbines will drive the generators. It was feared that the floating pumice would wear the rotor vanes of the turbines, but on seeing the condition of the turbines at Waikino after 12 years' work, this may be dis-

with 7,760,248 tons in August, and 7,600,233 tons in July. The total to October 1 this year was 36,338,382 tons, against 24,837,137 tons to October 1, 1911, an increase of 11,501,245 tons. The table below gives the September and season shipments by ports and the corresponding figures for 1911, all in gross tons:

	Sept. 1912	Sept. 1911,	To Oct. 1, 1912,	To Oct. 1, 1911.
Escanaba ....	770,974	668,595	4,010,985	3,086,847
Marquette ...	566,178	367,964	2,567,578	1,568,711
Ashland .....	757,764	368,945	3,623,161	1,878,786
Superior ....	2,031,086	1,563,836	11,097,276	7,946,109
Duluth .....	1,652,735	1,131,247	7,729,187	5,501,364
Two Harbors.	1,508,493	1,130,482	7,310,195	4,855,320
Total .....	7,287,230	5,231,069	36,338,382	24,837,137
1912 inc...		2,056,161		11,501,245

The heavy shipments from Superior show the great activity at the Hill properties which are operated by the United States Steel Corporation. It is evident that unless conditions on the lakes are unexpectedly unfavorable in November, the total brought down this year will be well about the 45,000,000-ton mark.

DURING September the Tomboy mill was in operation 28 days, crushing 10,000 tons of ore which yielded bullion worth \$50,500 and concentrate worth \$33,500. Expenses of operation were \$44,000, and \$11,300 was spent on permanent improvement.

# Development of the Reverberatory Copper Smelting Furnace

By E. P. MATHEWSON

## HISTORICAL

The early development of the reverberatory furnace for smelting copper ores was the work of the Welsh smelters, particularly those of Swansea. The first record of a reverberatory furnace is made by Jars, who states that in 1765 copper smelting was effected in reverberatory furnaces at Middleton-Tyas, in Yorkshire, England. The first patent, of any importance, for improvements in reverberatory furnaces was granted to Thomas Williams in 1778 for the granulation of the regulus. The next was that of William Evetts, in Sheffield, in 1812, for cooling of the fire-bridge by the admission of air. Charge hoppers above the furnaces were in common use in 1848. The size of the hearth of the furnaces, about the beginning of the nineteenth century, was commonly 11 by 8 feet.

No material development was made until the Welsh process was brought to Colorado, where Richard Pearce, as manager of the Argo works near Denver, developed the

\*A paper presented at the Eighth International Congress of Applied Chemistry, and reprinted by permission of the author.

furnace to meet the requirements of a custom plant, under keen competition with lead-silver smelting plants using blast-furnaces. His improvements are outlined in Fig. 1, elaborated by permission, from E. D. Peters' 'Modern Copper Smelting,' to which the reader is referred for further details. This figure shows that the furnaces were, in 1878, 9 ft. 8 in. by 15 ft. in hearth; and in 1894 16 by 35 ft., while the capacity of the furnace had been increased from 12 tons per 24 hours to 50 tons. The next step in development was made in Butte, Montana, by the Colorado Smelting Co., this plant being at that time affiliated with the Argo works, so that Mr. Pearce's influence was apparent. This was the lengthening of the hearth to 50 ft., with consequent increase in capacity to 105 tons in 24 hours. The first furnace of this size, built from the Colorado Smelting Co.'s plans, was constructed at the Butte & Boston plant in Butte, Montana, in the year 1900. Details of Montana practice, up to the year 1902, will be found in a paper by H. O. Hofman entitled 'Notes on the Metallurgy of Copper of Montana,' *Trans. A. I. M. E.*, Vol. XXXIV, pp. 258-316. The 50-ft. furnace became very popular in Butte and Anaconda, and when the Washoe smelter was built, in 1900-1902, the 50-

\* Converter slag is poured into Reverberatories at these plants, thus raising copper assay, as only 75% of copper in Converter slag is recovered.

ft. reverberatory was adopted and 14 of these furnaces constructed.

The next improvement was the addition of limestone to the charge of the calciners so that it was thoroughly mixed into the charge before dropping the charge into the reverberatories. This apparently insignificant change resulted in greatly increasing the capacity of the furnace. The next step was the building of a furnace with a 60-ft. hearth, the results from which were so encouraging that a furnace with a hearth 85 ft. long was tried, with corresponding increase in tonnage. Then a radical step was taken at the Washoe plant, of connecting two 50-ft. furnaces, making a single furnace with a hearth 102 ft. long. The saving in fuel and the increased tonnage caused the management to build a furnace with a hearth 116 ft. long. The results of these experiments are given in the following tabulation, compiled by William Wraith, superintendent of the Washoe smelter.

#### EFFECT OF LENGTHENING REVERBERATORY FURNACES AT THE WASHOE SMELTER

The reverberatory furnaces as originally built at the Washoe smelter had a hearth area of 19 by 50 ft. After some months of operation it was decided that a longer furnace could be operated to better advantage. To determine the length best suited to the conditions, one furnace was lengthened to 60 ft., another to 85 ft., another to 102 ft., another to 112 ft., and finally to 116 ft. in length. The draft at the bridge wall was from  $\frac{3}{4}$  to 1 in. of water; the fire-box area 7 by 16 ft. The coal used was from the Anaconda Copper Mining Co.'s mines at Diamondville, Wyoming, having the following average proximate analysis and thermal value:

Analysis:  $H_2O$ , 6.13%; volatile matter, 36.28; fixed carbon, 45.42; and ash, 12.17%.

Thermal value: Wet coal, 11,710 b.t.u.; dry coal, 12,390 b.t.u.

There was some variation in the quality of the coal, the ash ranging from 6 to 16% and the thermal value from 10,750 to 12,000 b.t.u. per pound of wet coal, or from 11,000 to 13,200 b.t.u. per pound of dry coal. There is also some variation in material smelted and in manipulation by the different furnace crews.

Reverberatory furnaces in different localities present

their own conditions, and the lengths of furnaces will be found to be functions of the type of fuel, draft, tonnage to be smelted, and investment.

Hearth areas of furnaces, ft...	Tonnage per 24 hours .....	Ratios of cuprous material to coal.....	Averages .....
19 by 50 .....	121.74	2.75	For 1 year
19 by 60 .....	190.7	3.94	For 7 months
19 by 85 .....	234.1	4.13	For 7 months
19 by 102 .....	264.9	4.31	For 4 years
19 by 112 .....	267.1	4.30	For 4 years
19 by 116 .....	270.1	4.19	For 4 years

The percentage of copper in the slags from the different furnaces averaged as follows:

Furnace.	Hearth length, ft.	Period.	Copper, %.
No. 1 .....	50	Sept. 1903-Mar. 1904 ..	0.50
No. 6 .....	60	Mar.-Sept. 1904 .....	0.44
No. 1 .....	85	May-Dec. 1904 .....	0.42
No. 1 .....	102	Jan. 1906-May 1911 ...	0.39
No. 4 .....	112	July 1906-May 1911 ...	0.38
No. 1 .....	116	Jan. 1906-May 1911 ...	0.36

About this time the Garfield plant of the American Smelters Securities Co. was being built near Salt Lake City, Utah, and for that plant furnaces with 100-ft. hearths were adopted. Then the plant at Humboldt, Arizona, of the Consolidated Arizona Smelting Co., built two furnaces with 100-ft. hearths, using oil for fuel. The Steptoe plant at McGill, Nevada, followed with five furnaces with hearths 110 ft. long, coal-fired, changed to oil-firing in 1911. The Cananea Copper Co. put in one furnace with hearth 100 ft. long, for flue-dust, in 1906, followed by a second in 1911. Experiments were tried with coal-dust firing, but cheap oil being available, the coal-dust experiments were discontinued and oil substituted. The reader is referred to L. D. Ricketts' article on experiments in

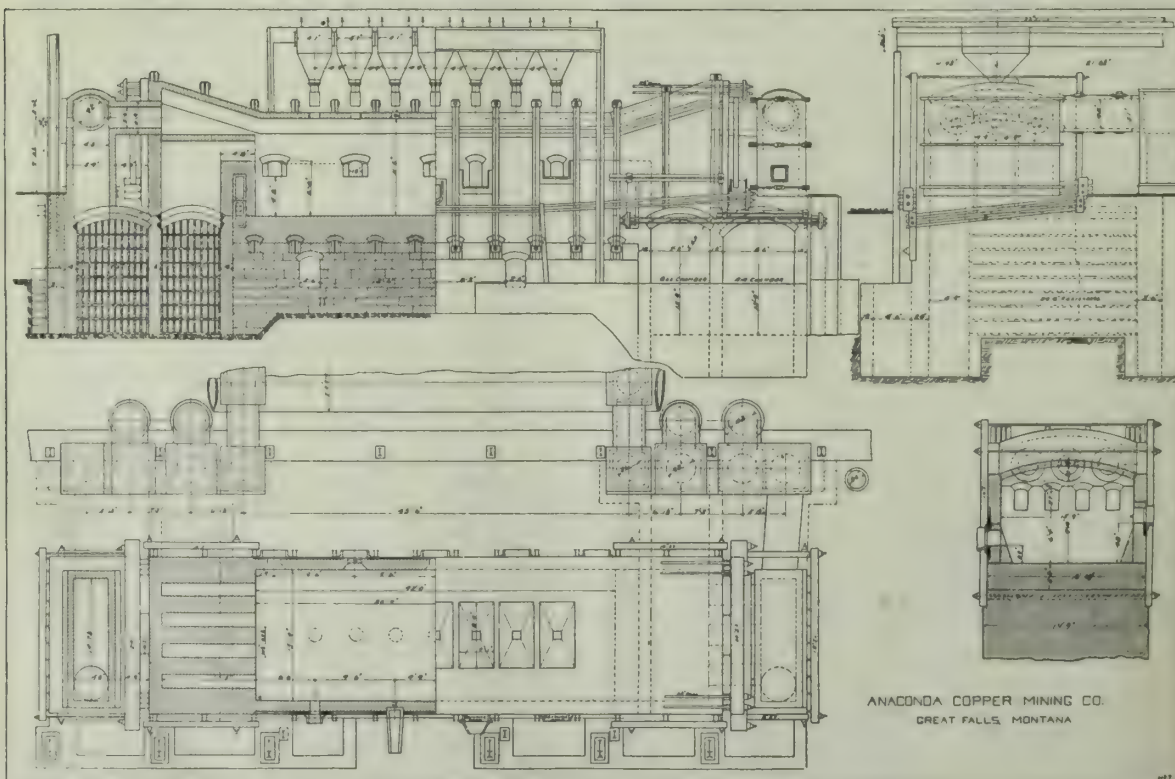

FIG. 3. ANACONDA PLANT; PLAN, ELEVATION, AND BOILERS.

reverberatory practice at Cananea (*Trans. Institute of Mining and Metallurgy*, Vol. XIX, p. 147).

The accompanying table gives important data on the best modern installations of reverberatory furnaces, and the table of analyses gives the details of the chemical composition of the charge, the slag, the matte, and the fuel. The features that distinguish the modern reverberatory are its length, solid bottom (monolith of fused quartz), structural steel plate forming the bridge-wall, frequent charging, infrequent skimming of slag, the large body of molten matte retained in the furnace to assist in melting and distributing the charge, no leveling of charge by means of rabble; thick roof (15 to 20 in. of silica brick); fetling only once a month in many plants, practically continuous operation; recovery of waste heat in the form of steam; and, where coal is used for fuel, the recovery of the unburned coal from the ashes.

During the development of the reverberatory furnace to its present state of efficiency, a great many schemes were tried and abandoned; for example, the pre-heating of the air by passing it under the furnace bottom or around the walls of the flue or fire-box, and forced blast under the grate.

A great variety of fuel has been and is being used in reverberatory practice; for example, at Kyshtim, Perm Government, Russia, producer gas from wood is in use, with gratifying results. At this plant the hearth of the furnace is about 35 ft. between ports and 15 ft. wide; the gas is made from pine wood and the moisture and tar scrubbed from the gas before going to the furnace. The following data, furnished by A. H. Allen, regarding the furnaces will be of interest:

- Surface of air checker, 869 sq. m.; useful area, 688 sq. m.
- Sectional area of air checker, 49 sq. m.
- Surface of gas checker, 698 sq. m.; useful area, 559 sq. m.
- Sectional area of gas checker, 46 sq. m.
- Average gas analysis, per cent: CO<sub>2</sub>, 7.47; CO, 26.22; H, 8.3; CH<sub>4</sub>, 5.86; C<sub>2</sub>H<sub>6</sub>, 0.79.
- Analysis of products of combustion in stack, per cent: CO<sub>2</sub>, 12.2; O, 6.3; N, 71.5.
- Pressure at reversing valve, 3 mm. water. Suction at stack, 25 mm.
- Temperature of gas entering regenerator, 68°C.; temperature entering stack, 385°C.

Average temperature of furnace, 1600°C. Maximum temperature at ports, 2000°C. Temperature entering checker, 1300°C.

The charge was mainly flue-dust, but there was some green ore; some silicious oxidized copper ore; some converter cleanings, etc., mixed with it. I cannot give the composition of the charge, but 90% of it was flue-dust and green fine. From January to September 1910 the furnace was in operation 166 days, with results as follows:

Amount smelted, tons .....	10,690
Wood consumed in producers, cords .....	3,417
Matte produced, tons .....	3,326
Contents of matte, tons of copper.....	283
Assay, % Cu .....	8.5
Contents charge, copper, tons.....	330.8
Average assay charge, % Cu.....	3.1

The work is chiefly interesting for the extremely low fuel cost, which has been verified by an experienced engineer now on the ground. Wood at Kyshtim cost \$1.05 per cord delivered, so that the average fuel cost, over the 9-months period, was 33.6c. per short ton of charge. It results from the fact that the Russians in charge of the furnaces have had experience with gas-producers in iron works and made a gas of high calorific power.

KYSHTIM FLUE-DUST AND ORE ANALYSES

Sample taken from one month's production of flue-dust:

Per cent.		Per cent.	
SiO <sub>2</sub> .....	8.8	Cu .....	3.3
Fe .....	50.9	S .....	9.6

Sample from 6000-ton pile of flue-dust:

Per cent.		Per cent.	
SiO <sub>2</sub> .....	8.9	Cu .....	3.3
Fe .....	48.9	S .....	10.0
Cu, %.			

- Sample one week's production..... 3.38
- Sample of large pile (weight not given)..... 3.2
- Sample of large pile, made in 1907..... 1.8
- Average sample of raw ore used with flue-dust:

Per cent.		Per cent.	
SiO <sub>2</sub> .....	2.1	S .....	47.0
Fe .....	38.5	Cu .....	3.2
CaO .....	0.5		

FIG. 4. CANANEA OIL-FIRED FURNACE, PLAN AND SECTION.

At Cananea, Texas oil has been used; and at Humboldt, fuel oil from California. At the plant of the Steptoe company, at McGill, Nevada, fuel oil from California was introduced during 1911, with gratifying results. A great many different varieties of burners were tried, but a simple home-made burner, using air for atomizing the oil, has given the best results. A record performance at the Steptoe plant, McGill, Nevada, on December 17, 1911, is communicated by S. S. Sorensen, the superintendent, No. 1 furnace smelting 660 tons of total charge on an oil consumption of 5/8 bbl. of oil per ton of charge.

RECORD OF RUN OF NO. 1 REVERBERATORY FURNACE AND ANALYSIS OF CHARGE.

Total charge per furnace day, tons.....	666
Oil fired per furnace day, bbl.....	421
Coal equivalent of oil fired, tons.....	124.00
Total charge per bbl. of oil, tons.....	1.58
Oil, bbl. per ton of total charge.....	0.63
Equivalent gross coal as percentage of total charge.	18.60

Components of Charge as Percentage of Total Charge.

Calceine .....	60.1
Seconds .....	16.8
Converter hot slag .....	9.0
Fettling .....	3.9
Limestone .....	9.6
Flue-dust .....	0.6

SLAG (Assay and Analysis)

Cu .....	0.40
SiO <sub>2</sub> .....	44.00
Fe .....	34.30
CaO .....	8.60
Al <sub>2</sub> O <sub>3</sub> .....	7.40
Oxygen ratio .....	2.72
Grade of matte, % Cu.....	40.40

Draft:	Water, in.
Bridge .....	0.35
Throat .....	0.83
Stack .....	1.25
Temperature of verb, degrees F.....	1910
Infusibility factor of calceine.....	1.5
Burners, large Steptoe, high-pressure.....	7

At the Washoe plant, at Anaconda, coal is used for fuel, and a record run for one furnace was the smelting of 402½ tons of charge in 24 hours with a fuel ratio of 1 ton of fuel to 6.45 tons of charge. At Great Falls, Montana, the fuel is producer gas, but the producers are too far away from the furnaces to get the best results; new furnaces are to be built at this plant in which the producers will be placed in close proximity to the furnaces and a much greater efficiency will be obtained.

The Canadian Copper Co. is experimenting with pulverized coal as fuel, but the furnaces have not been in operation long enough to give data of any great value. David H. Browne, the superintendent, writes that he is greatly pleased with the performance of the furnaces up to date. The objections to the use of pulverized coal in reverberatory practice have been the settling on the top of the charge of ash and unburned fuel and the clogging of the flues with ashes. The Canadian Copper Co. has a peculiar condition, in that the charge is basic, and that the addition of silica, in the form of coal-ash, is rather welcome than otherwise. To avoid the other objection the coal is pulverized extremely fine, and the surplus ash goes out with the gaseous products of combustion.

At nearly all modern plants, waste-heat boilers are employed. Silica brick is used almost exclusively in the construction of the lining and roof of the modern reverberatory furnaces for copper smelting, and it is now possible to obtain silica brick, of excellent quality, all over the United States at reasonable cost.

DURING the quarter ended June 30, 1912, the output of ore and metals from mines in Tasmania was as follows:

	Quantity.	Value.
Gold recovered, ounces.....	13,748.76	\$291,000
Silver-lead ore produced, tons....	22,316	425,000
Blister copper produced, tons....	1,330	566,500
Copper ore and copper, tons....	270	9,300
Tin ore produced, tons.....	953	650,000
Coal raised, tons .....	14,686	33,000
Wolfram ore produced, tons.....	15	7,800
Bismuth, tons .....	1.75	3,400
Osmiridium, ounces .....	140.53	5,500

Total value ..... \$1,991,500

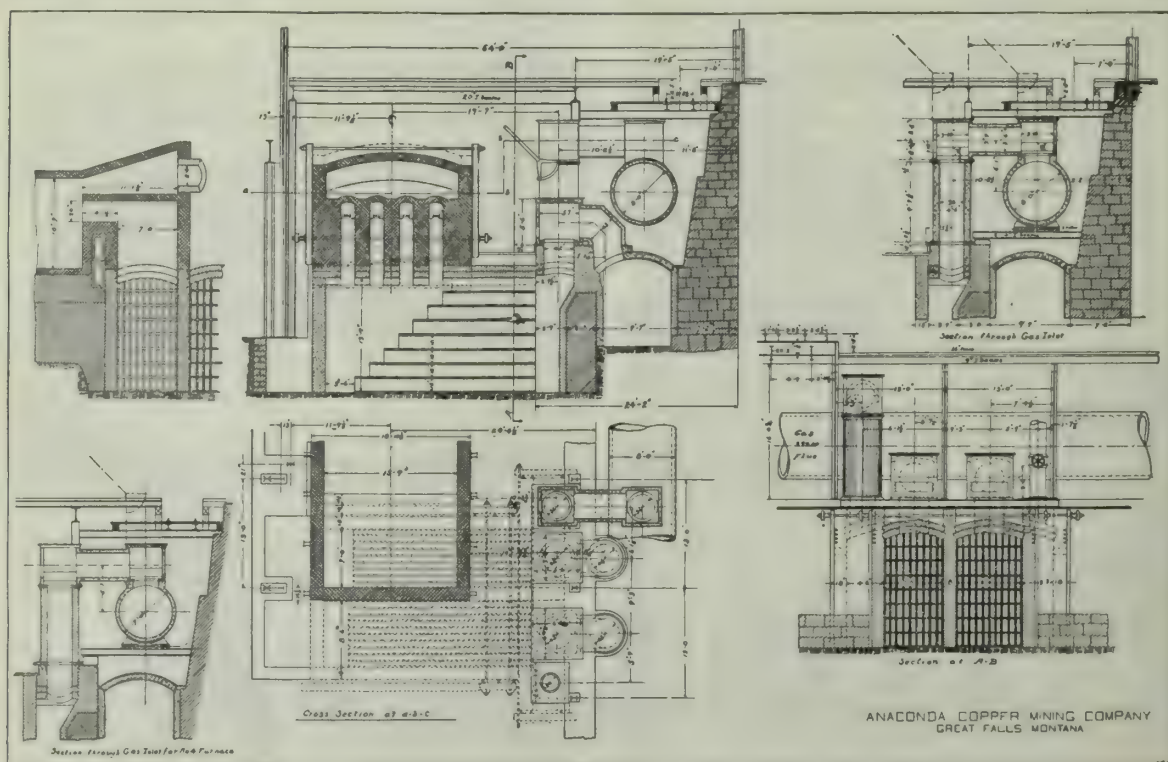

FIG. 5. GREAT FALLS, CHECKER WORK AND SECTION THROUGH FLUE.

## Separation of Base Metals in Cyanide Solution for Quantitative Determination

By P. L. GUPPY and DOUGLAS WATERMAN

In the treatment of silver sulphide ores by the cyanide process, free alkaline sulphides are carried into solution. Lead acetate is often used as a precipitant for these free sulphides. Any excess of lead acetate over the amount required to accomplish this purpose is undesirable, as it is carried to the zinc-boxes in the form of sodium plumbate and there deposited with the silver. This entails a needless waste, not only of the acetate, but of the zinc as well, which is consumed in the process of replacement. An excess of lead acetate led to the production of a base bullion. It is highly desirable, therefore, to know if lead is present in excess. The amount of zinc and copper in solution is also of importance at times. By the following scheme of analysis these and other base metals may be recognized and separated for quantitative determination by any of the well known methods.

Partly fill an Erlenmeyer flask with 500 c.c. of the cyanide solution to be analyzed. Place a small glass funnel, with stem broken off, in the neck of the flask, which will effectually prevent the formation of excessive quantities of steam, thus avoiding all danger of the solution boiling over.

I. Add 15 c.c. concentrated HCl, salts of copper, a portion of the silver, and ferrocyanides of the heavier metals will be precipitated. Evaporate to a volume of 100 c.c. and allow the solution to cool. Add 300 c.c. of bromine water and boil until all the bromine is expelled. This should bring the ferro-cyanides of zinc, by oxidation, into soluble form.

Dilute to 400 c.c. with boiling water, and pass a rapid current of hydrogen sulphide through the solution until precipitation is complete. On withdrawing the current of  $H_2S$  the precipitate should settle rapidly, leaving the solution clear, showing that precipitation is complete. Filter through an 11-cm. paper and wash the precipitate with  $H_2S$  water. The result then is:

- (a) Precipitate containing silver, gold, copper, and lead; antimony and arsenic if present.
- (b) Filtrate containing zinc, manganese, and other metals not precipitated by  $H_2S$ .

II. If it is desired to test for antimony and arsenic, the funnel is inverted over an 8-oz. beaker, into which the precipitate is washed with a fine jet from a wash-bottle; 15 or 20 c.c. of sodium sulphide is added, and the contents of the beaker digested for 10 or 15 min. to bring the antimony and arsenic into solution.

Filter through the same filter-paper into a clean beaker, wash with dilute sodium sulphide, and finally with a little warm water. On acidifying the filtrate with HCl the presence of antimony or arsenic may be readily detected; antimony giving an orange-colored precipitate, and arsenic a yellow.

These substances may be determined quantitatively by any of the usual means, but an excellent method for determining small quantities of antimony and arsenic, with full explanations of necessary precautions, will be found in the first edition of Fresenius' 'Quantitative Analysis.'

III. Wash the bulk of the precipitate (a) into a casserole with hot water. Remove the filter-paper and spread over the convex surface of a watch-glass. The adhering precipitate is dissolved with hot dilute nitric acid and added to the contents of the casserole. (Care should be taken that none of the filter-paper is allowed to fall into the casserole.) Cover the casserole and heat until precipitate is dissolved. Add 20 c.c. concentrated  $H_2SO_4$  and evaporate on hot plate until copious white fumes are given off. When cool, rinse the contents of the casserole with a little cold water into a clean beaker. The presence of lead may be readily detected by the white granular

appearance of the precipitate in the bottom of the beaker, and is easily distinguished from either the chloride or the sulphate of silver, which may also have been precipitated.

IV. Filter and wash with sulphuric acid diluted 4 to 1.

(c) Precipitate containing lead (if present) and a small quantity of silver.

(d) Filtrate containing copper and nearly all of the silver.

To the filtrate (d) add just enough sodium chloride solution to precipitate the silver, which is then removed by filtration. The copper in solution is precipitated on aluminum foil. For quantitative determination of both the lead and copper, reference should be made to Low's 'Technical Methods of Ore Analysis,' fifth edition, pp. 144 and 84.

V. To the filtrate (b) containing zinc and manganese add 20 c.c. more HCl and boil to expel the hydrogen sulphide. Add a few drops of nitric acid and heat for five minutes. Add 5 gm. ammonium chloride, and then ammonia until the solution is alkaline.

(e) Precipitate containing iron and aluminum.

(f) Filtrate containing zinc and manganese.

The iron in precipitate (e) may be determined quantitatively and expressed in terms of ferro-cyanide if desired.

VI. To the filtrate (f) add a slight excess of ammonium sulphide to precipitate the zinc and manganese. Nickel and cobalt would also be precipitated at this point, but as they are of rare occurrence their treatment will not be considered.

Dissolve the precipitate in hot dilute HCl and boil until the  $H_2S$  is completely expelled. Cool and add ammonia in slight excess. Add bromine water until the solution is well colored by this reagent, and boil. Manganese will be precipitated and may be determined by the method given in the first edition of Fresenius' 'Quantitative Analysis.'

The zinc will remain in the filtrate. Acidify with HCl, add 3 c.c. in excess, and evaporate down to 250 c.c. It may then be determined as outlined in Low's 'Technical Methods of Ore Analysis.'

## Platinum Deposits in Mongolia

ST. PETERSBURG CORRESPONDENCE

The condition of the platinum market is firm but inactive and there is practically no change in price to be reported, nor has there been for a considerable time. The same influences are active in maintaining the market at its present level, notwithstanding the remarkable absence of demand from western Europe, and speculators are quite willing to add to their holdings. It is stated that rich deposits of platinum have been found near the town of Alkobek in Chinese Mongolia. A. L. Shmykoff, who has had experience in the gold industries of central Siberia, has started to take the necessary exploration for detailed investigation of this deposit.

It should be stated here that in 1904, E. N. Korotkoff, while exploring in central Siberia, obtained from the Sapota, a race of Mongolians, a nugget of platinum weighing over  $2\frac{1}{2}$  zolotniks. Such nuggets of platinum, as in the Urals forty to fifty years ago, are used by the Sapota as shot when they hunt game and wild animals. The nugget acquired by Mr. Korotkoff was sent to Ekaterinburg, but the Urals platinum authorities did not regard it as significant, presuming that it had been found in the Urals. Now, in view of the recent discoveries in Mongolia, this occurrence is remembered, and it is believed that platinum will be found in the mountain lands of Sayansky.

COPPER has been discovered in the island of Burray, Orkney, the property of Lord Zetland. Samples which have been tested have given generally satisfactory results. Steps are now being taken to ascertain whether copper exists in workable amounts.

## Mexican and California Petroleum

The two oil-producing companies, California Petroleum Co. and Mexican Petroleum Co., whose securities were listed on the New York Stock Exchange this fall, have a total authorized capitalization of \$85,000,000, of which \$73,500,000 has been issued. The *Boston News Bureau* gives the details of their financial structure. The following table shows the manner in which this stock is divided:

Preferred	Cal. Petrol. Co.	Mex. Petrol. Co.
Authorized .....	\$17,500,000	\$12,000,000
Issued .....	12,000,000	12,000,000
Authorized .....	17,500,000	38,000,000
Issued .....	13,500,000	*36,000,000

Total issued.....\$25,500,000 \$48,000,000

\*Including \$4,000,000 set aside for bond conversion.

Outstanding bonded indebtedness of the two companies and their subsidiaries is as follows:

Six per cent bonds \$1,604,200 \$2,913,200

\*Including \$1,300,000 Mexican Petroleum Co., Ltd., first and refunding sinking fund bonds.

Both corporations are holding companies. Mexican Petroleum Co., Ltd., owning 95% of the capital stock of Mexican Petroleum Co. of California, and the entire capital stock, excepting directors' shares, of the Huasteca Petroleum Co., the Tamiahua Petroleum Co., and the Tuxpam Petroleum Co. The operating companies own or control about 600,000 acres, or nearly 1000 square miles, 75% being held in fee and the remainder under long-time leases. The value of these properties has been placed at \$73,000,000 by L. C. White, state geologist of West Virginia. Development is as follows: 26 completed oil wells with a capacity of 60,000 to 70,000 bbl. per day, 15 km. of railroad line, 212 km. of 8-in. pipe-line with a capacity of 80,000 bbl. of oil per day, about 1000 acres of terminal property at Tampico harbor, steel tanks and storage reservoirs with a capacity of 5,750,000 bbl. and an additional storage capacity of 2,016,000 bbl. ordered or completed, power-plants and refineries, and four tank buildings with a capacity of about 220,000 bbl. of oil. Earnings have been as follows, before interest and depreciation, but after deducting proportion of earnings attributable to stock not owned by the holding company:

1911 .....	\$2,648,544
1910 .....	1,667,487
1909 .....	794,591
1908 .....	853,748
1907 .....	757,384

The Mexican Petroleum Co., Ltd., is now earning at the rate of about 8% per year on the common stock, and indications for much larger earnings next year are excellent. The common will probably be placed upon a 6% basis in the first quarter of 1912. The California Petroleum Co. owns stocks of the following companies as indicated below:

	Authorized.	Issued.	Pet. Corp.
Am. Pet. Co., common	\$12,500,000	\$12,468,000	*9,974,720
Am. Pet. Co. preferred	2,500,000	2,095,000	*1,676,720
Am. Oil Co. ....	25,000,000	18,303,800	*14,643,040
Am. Oil Co. 10% bonds			
due 1900 .....	10,000,000	2,646,100	
Am. Pet. 6% bonds			
due 1919 .....	2,000,000	956,100	

\*These securities and \$3,400,158 cash were acquired in exchange for \$11,992,024 preferred stock and \$13,513,081 common stock of the California Petroleum Corporation, the latter now being represented by voting trust certificates.

As indicated above, the California Petroleum Corporation has purchased and is holding stock, amounting 80% of the stocks of the American Petroleum Co. and the American Oilfields

Co. and will acquire \$1,000,000 of the \$2,646,100 outstanding bonds of the American Oilfields Co. The companies in which the holding company has an 80% interest have land holdings of about 18,000 acres, of which over 3000 acres are proved lands. There are prospects for proving up a substantial portion of the remaining 15,000 acres. These companies have 103 producing oil wells with an average production of 15,400 bbl. per day. Ralph Arnold, consulting geologist, places a valuation on the properties in excess of \$32,000,000 and estimates they contain 295,000,000 bbl. of oil. Earnings for the year ended December 31, 1911, after interest and provision for bond sinking funds, were \$1,943,000, and for seven months ended with July 1912, \$1,236,000.

## The Wallaroo and Moonta

MELBOURNE CORRESPONDENCE

In all the vast area of South Australia there is but one mining property of any importance. This consists of two mines, the Wallaroo and the Moonta, belonging to a single company, the Wallaroo & Moonta Mining & Smelting Co., Ltd., with an issued capital of \$1,000,000 in 160,000 fully paid shares, and additional 40,000 shares of \$10 being unissued. The amalgamation of the two mines was effected in 1890, but operations date back to 1860; and since then copper to the value of about \$75,000,000 has been produced, and dividends paid amounting to more than \$10,000,000. For a long time past, however, the state of the ore reserve has been anything but satisfactory, but nothing was declared officially until a statement was issued prior to the half-yearly meeting of shareholders to be held on September 24. This statement confesses that the underground operations at the Moonta have been gradually curtailed, "owing to the working out of the remnants of ore found, and the declining value of the ore being won from the mine," and goes on to say that, "the time has arrived for giving serious consideration to the advisability of closing down the mine." The statement, that the value of the ore has been declining, is not quite in accordance with facts, for the assay value of the ore handled was greater last year than it had been for some years previous. But this year has seen a decline of nearly 20%, so that there can be no doubt as to the correctness of the statement so far as concerns the present, nor is there any doubt as to the decrease of the ore reserve. This is estimated at 40,000 tons, assaying from 2 to 4% copper. This will give 18 months' work, and yield 1000 tons of copper, or thereabout. There is some prospecting to be done below the 1200-ft. level, but the general manager leaves it to the shareholders to express an opinion in regard to the undertaking of the work, since it is of a speculative character, and involves an expenditure of \$35,000. Concerning the outlook at the Wallaroo mine, no such definite statement is made; but it is remarked significantly enough that should copper remain at anything over \$350 per ton, "the Wallaroo can be worked profitably for a good many years to come." The inference is, of course, that with copper below that figure, work would be unremunerative. The total amount of ore and precipitate smelted from the two mines during the past year was between 30,000 and 31,000 tons, yielding about 2900 tons of refined copper. At the Wallaroo mine, cementation has been tried, but without much success, the copper being more easily recoverable by a flotation process. Fine-grinding machinery is being erected, and is expected to earn a net profit of \$150,000 with copper at \$350. At Moonta, tailing and slime has yielded from cementation a net profit of over \$900,000, after the entire cost of erection of the works had been met.

COLORADO river drains an area of approximately 300,000 square miles. The annual maximum flow varies from 50,000 to 150,000 second-feet in May, June, and July; the minimum flow varies from 2500 to 5000 second-feet in January and February; and the mean flow from 1894 to 1903 was 10,700, and from 1904 to 1910 was 25,400 second-feet.

The Hendryx Agitator on the Rand

JOHANNESBURG CORRESPONDENCE

The Mines Trials Committee has been recently testing the Hendryx agitator and an interesting account of the results has been published in the local mining journal, from an authoritative source, but clearly not from the Mines Trials Committee, because, unfortunately, it has decided not to published the results of the tests.

The following table gives results of actual tests made by the Mines Trials Committee at the Wolluter G. M. Co. plant.

Test No. and date. 1—March 11, 1912. 2—March 20, 1912.			
Product .....		Sand and slime.	Slime only.
Quantity and ratio.		Ore, 35 tons } Sol., 70 tons } 1:2	Ore, 35.03 tons } Sol., 70.00 tons } 1:2
Grading:			
+ 60.....		9.4%	
+ 90.....		19.3%	0.1%
+ 120.....		11.3%	0.4%
- 120.....		60.0%	99.5%
Average assay of charge		2.55 dwt.	1.65 dwt.
Solution strength per ton of ore:			
Start .....		0.136	0.042
Finish .....		0.132	0.040
Loss .....		0.004	0.002
Extraction by solution:			
Hr.	Assay ratio, dwt.	Dwt.	
1 .....	1.25	1.0	
2 .....	2.00	1.16	
3 .....	2.20	1.38	
4 .....	2.30	1.52	
5 .....	2.30	1.52	
6 .....	2.40		
7 .....	2.40		
Extraction by KCN solution .....		94.1%	92.0%
Washed residue assay.		0.281 dwt.	0.05 dwt.
Comparative extraction:			
Residue assay .....		93.06%	97.0%
Solution assay .....		94.1%	92.0%

The above figures represent the exact results obtained by the Mines Trials Committee (Johannesburg, Transvaal) in the Hendryx agitator upon residues after amalgamation. The following figures show the total extraction from the original ore, including amalgamation in the mill:

Total extraction by amalgamation and KCN solution:			
Figured from residue..		97.9%	99.0%
Figured from solution.		97.9%	98.0%

H. Stadler who was in charge of the trials on behalf of the Mines Trials Committee, states that there are other important facts not published in the results, but which ought to be taken into account. He goes on to explain that in the tests the cyanide had been added in the form of salt, thereby ensuring greater efficiency than by using the ordinary stock solution, while the consumption of cyanide quoted only refers to that used during agitation and excludes losses incurred in the extractor boxes and that going to the dump. The fact that the pulp was heated to a temperature of 90° F. is not made sufficiently plain in the published results of the tests, while it must not be overlooked that the percentages of extraction were calculated from the values of washed samples. Mr. Stadler further states that he considers the statement published in the official report, that "as much or more of the gold and silver can be dissolved in one hour by the use of the Hendryx agitator

as can be dissolved in 24 hours by the usual methods of percolation as somewhat misleading, and explains that in the Hendryx 18-ft. agitator only about 35 tons of mixed sand and slime is agitated during 7 hours, while in every day practice on the Rand, up to 400 tons of sand is treated in 5 to 7 days including the subsequent operations of transfer of sand, settling, washing, re-settling, and emptying of the treatment vat which are not included in the 7 hours mentioned as required by the Hendryx agitator. Mr. Stadler considers that figures relating to the costs should also have been supplied, and goes on to express regret that the results of various tests made by the Mines Trials Committee, particularly those relating to tube milling made during the last three years do not appear. The apparent reason for the non-publication of the results of the tests made by the Mines Trials Committee is the desire that they should only be available to those contributing to the cost.

Progress in the Joplin District

Extensive development in all districts has brought old mines back again. While there is more or less new development, and new fields are producing a portion of the heavy shipments that are going out of the district, old ground is likewise playing a conspicuous part in the era of renewed activity. From the New Century Zinc & Lead Co.'s land at Galena, Kansas, heavy production is being made, and it is interesting to note that this ore comes, not from present-day mining operations, but from old dump piles that were discarded as worthless by pioneer operators who could name only the richest ore at the prices which then prevailed. This is only one instance of many similar ones. In the Galena district, especially, where numerous shallow hand-pig operations were conducted, rich boulder heaps accumulated, and the re-working of these is now netting a profit to the operators.

Higher ore prices make it possible for mining companies to handle thinner ore, and as a result the demand for sand jigs and slime tables has been heavy recently. New tables have been installed at the Wilson mines at Duerweg, Missouri, at the Harmon mill, Galena, Kansas, and at many other plants throughout the district. Clean-ups from slime tables now command a fairly good price, and much of the fine ore that formerly was wasted is now finding its way to the smelters.

Development of exceptional importance has been initiated by O. W. Sparks, of Galena, Kansas, in the old Klondike district, northwest of Joplin. He has constructed large concentrating plants at two new mines, which are known as the Yellow Jacket and the Yellow Pup. Both mines are exceptionally rich at this time, the aggregate production being about 650,000 lb. of concentrate weekly. This is a phenomenal output, but whether it will long continue is problematical. The ground in that region is 'pockety,' and just how long a big orebody will continue cannot be foretold. Sparks claims to have drilled the ground thoroughly and to have found ore in many of the holes. Other examples of rich pocket mines, which are holding the limelight in the district at this time for their heavy production, are the Poochonas, yielding 150 tons of blende per week, and the Spring Hill, yielding about 175 tons per week. The average mill of the district cleans up about 30 to 40 tons per week.

THE Scott expedition to Baffin Land in search of gold has returned to St. Johns without meeting with success. It reports having discovered enormous deposits of coal and iron, and has brought back the survivors of the Munn expedition. Munn is a British army officer who was in command of an expedition to the same place and on the same errand. He lost his ship in Poodis coast. It was crushed by ice floes. Munn found gold, but his search was discontinued owing to the loss of his ship. When he was saved, only seven barrels of bread and two barrels of beef remained, and no clothes.

## Mexican and California Petroleum

The two oil-producing companies, California Petroleum Co. and Mexican Petroleum Co., whose securities were listed on the New York Stock Exchange this fall, have a total authorized capitalization of \$85,000,000, of which \$73,500,000 has been issued. The *Boston News Bureau* gives the details of their financial structure. The following table shows the manner in which this stock is divided:

	Cal. Petrol. Co.	Mex. Petrol. Co.
Preferred:		
Authorized .....	\$17,500,000	\$12,000,000
Issued .....	12,000,000	12,000,000
Common:		
Authorized .....	17,500,000	38,000,000
Issued .....	13,500,000	*36,000,000
Total issued.....	\$25,500,000	\$48,000,000

\*Including \$4,000,000 set aside for bond conversion.

Outstanding bonded indebtedness of the two companies and their subsidiaries is as follows:

Six per cent bonds..... \$3,604,200      †\$2,913,200

†Including \$1,300,000 Mexican Petroleum Co., Ltd., first lien and refunding sinking fund bonds.

Both corporations are holding companies, Mexican Petroleum Co., Ltd., owning 95% of the capital stock of Mexican Petroleum Co. of California, and the entire capital stock, excepting directors' shares, of the Huasteca Petroleum Co., the Tamiahua Petroleum Co., and the Tuxpam Petroleum Co. The operating companies own or control about 600,000 acres, or nearly 1000 square miles, 75% being held in fee and the remainder under long-time leases. The value of these properties has been placed at \$73,000,000 by I. C. White, state geologist of West Virginia. Development is as follows: 26 completed oil wells with a capacity of 60,000 to 70,000 bbl. per day, 15 km. of railroad line, 212 km. of 8-in. pipe-line with a capacity of 80,000 bbl. of oil per day, about 1000 acres of terminal property at Tampico harbor, steel tanks and storage reservoirs with a capacity of 5,750,000 bbl. and an additional storage capacity of 2,016,000 bbl. ordered or completed, power-plants and refineries, and four tank buildings with a capacity of about 220,000 bbl. of oil. Earnings have been as follows, before interest and depreciation, but after deducting proportion of earnings applicable to stock not owned by the holding company:

1911 .....	\$2,648,544
1910 .....	1,667,487
1909 .....	794,591
1908 .....	853,748
1907 .....	757,384

The Mexican Petroleum Co., Ltd., is now earning at the rate of about 9% per year on the common stock, and indications for much larger earnings next year are excellent. The common will probably be placed upon a 6% basis in the first quarter of 1912. The California Petroleum Co. owns stocks of the following companies as indicated below:

	Owned by Cal.		
	Authorized.	Issued.	Pet. Corp.
Am. Pet. Co., common.....	\$12,500,000	\$12,468,000	*9,974,720
Am. Pet. 6% preferred .....	2,500,900	2,095,000	*1,676,720
Am. Oil Co.....	25,000,000	18,303,800	*14,643,040
Am. Oil Co. 6% bonds,			
due 1930.....	10,000,000	2,646,100	.....
Am. Pet. 6% bonds,			
due 1910.....	2,000,000	956,100	.....

\*These securities and \$3,400,158 cash were acquired in exchange for \$11,992,024 preferred stock and \$13,513,081 common stock of the California Petroleum Corporation, the latter now being represented by voting trust certificates.

As indicated above, the California Petroleum Corporation for its present outstanding stock, acquired 80% of the stocks of the American Petroleum Co. and the American Oilfields

Co. and will acquire \$1,000,000 of the \$2,646,100 outstanding 6% bonds of the American Oilfields Co. The companies in which the holding company has an 80% interest have land holdings of about 18,000 acres, of which over 3000 acres are proved lands. There are prospects for proving up a substantial portion of the remaining 15,000 acres. These companies have 103 producing oil wells with an average production of 15,400 bbl. per day. Ralph Arnold, consulting geologist, places a valuation on the properties in excess of \$32,000,000 and estimates they contain 295,000,000 bbl. of oil. Earnings for the year ended December 31, 1911, after interest and provision for bond sinking funds, were \$1,943,000, and for seven months ended with July 1912, \$1,236,000.

## The Wallaroo and Moonta

MELBOURNE CORRESPONDENCE

In all the vast area of South Australia there is but one mining property of any importance. This consists of two mines, the Wallaroo and the Moonta, belonging to a single company, the Wallaroo & Moonta Mining & Smelting Co., Ltd., with an issued capital of \$1,000,000 in 160,000 fully paid shares, and additional 40,000 shares of \$10 being unissued. The amalgamation of the two mines was effected in 1890, but operations date back to 1860; and since then copper to the value of about \$75,000,000 has been produced, and dividends paid amounting to more than \$10,000,000. For a long time past, however, the state of the ore reserve has been anything but satisfactory, but nothing was declared officially until a statement was issued prior to the half-yearly meeting of shareholders to be held on September 24. This statement confesses that the underground operations at the Moonta have been gradually curtailed, "owing to the working out of the remnants of ore found, and the declining value of the ore being won from the mine," and goes on to say that, "the time has arrived for giving serious consideration to the advisability of closing down the mine." The statement, that the value of the ore has been declining, is not quite in accordance with facts, for the assay value of the ore handled was greater last year than it had been for some years previous. But this year has seen a decline of nearly 20%, so that there can be no doubt as to the correctness of the statement so far as concerns the present, nor is there any doubt as to the decrease of the ore reserve. This is estimated at 40,000 tons, assaying from 2 to 4% copper. This will give 18 months' work, and yield 1000 tons of copper, or thereabout. There is some prospecting to be done below the 1200-ft. level, but the general manager leaves it to the shareholders to express an opinion in regard to the undertaking of the work, since it is of a speculative character, and involves an expenditure of \$35,000. Concerning the outlook at the Wallaroo mine, no such definite statement is made; but it is remarked significantly enough that should copper remain at anything over \$350 per ton, "the Wallaroo can be worked profitably for a good many years to come." The inference is, of course, that with copper below that figure, work would be unremunerative. The total amount of ore and precipitate smelted from the two mines during the past year was between 30,000 and 31,000 tons, yielding about 2900 tons of refined copper. At the Wallaroo mine, cementation has been tried, but without much success, the copper being more easily recoverable by a flotation process. Fine-grinding machinery is being erected, and is expected to earn a net profit of \$150,000 with copper at \$350. At Moonta, tailing and slime has yielded from cementation a net profit of over \$900,000, after the entire cost of erection of the works had been met.

COLORADO river drains an area of approximately 300,000 square miles. The annual maximum flow varies from 50,000 to 150,000 second-feet in May, June, and July; the minimum flow varies from 2500 to 5000 second-feet in January and February; and the mean flow from 1894 to 1903 was 10,700, and from 1904 to 1910 was 25,400 second-feet.

The Hendryx Agitator on the Rand

JOHANNESBURG CORRESPONDENCE

The Mines Trials Committee has been recently testing the Hendryx agitator and an interesting account of the results has been published in the local mining journal, from an authoritative source, but clearly not from the Mines Trials Committee, because, unfortunately, it has decided not to published the results of the tests.

The following table gives results of actual tests made by the Mines Trials Committee at the Wolhuter G. M. Co. plant.

Test No. and date. 1—March 11, 1912. 2—March 20, 1912.			
Product .....	Sand and slime.		Slime only.
Quantity and ratio.	Ore, 35 tons } Sol., 70 tons } 1:2		Ore, 35.03 tons } Sol., 70.00 tons } 1:2
Grading:			
+ 60.....	9.4%		
+ 90.....	19.3%		0.1%
+ 120.....	11.3%		0.4%
- 120.....	60.0%		99.5%
Average assay of charge	2.55 dwt.		1.65 dwt.
Solution strength per ton of ore:			
Start .....	0.136		0.042
Finish .....	0.132		0.040
Loss .....	0.004		0.002
Extraction by solution:			
Hr.	Assay ratio, dwt.		Dwt.
1 .....	1.25		1.0
2 .....	2.00		1.16
3 .....	2.20		1.38
4 .....	2.30		1.52
5 .....	2.30		1.52
6 .....	2.40		
7 .....	2.40		
Extraction by KCN solution .....	94.1%		92.0%
Washed residue assay.	0.281 dwt.		0.05 dwt.
Comparative extraction:			
Residue assue .....	93.06%		97.0%
Solution assay ....	94.1%		92.0%
The above figures represent the exact results obtained by the Mines Trials Committee (Johannesburg, Transvaal) in the Hendryx agitator upon residues after amalgamation. The following figures show the total extraction from the original ore, including amalgamation in the mill:			
Total extraction by amalgamation and KCN solution:			
Figured from residue..	97.9%		99.0%
Figured from solution.	97.9%		98.0%

H. Stadler who was in charge of the trials on behalf of the Mines Trials Committee, states that there are other important facts not published in the results, but which ought to be taken into account. He goes on to explain that in the tests the cyanide had been added in the form of salt, thereby ensuring greater efficiency than by using the ordinary stock solution, while the consumption of cyanide quoted only refers to that used during agitation and excludes losses incurred in the extractor boxes and that going to the dump. The fact that the pulp was heated to a temperature of 90°F. is not made sufficiently plain in the published results of the tests, while it must not be overlooked that the percentages of extraction were calculated from the values of washed samples. Mr. Stadler further states that he considers the statement pulished in the official report, that "as much or more of the gold and silver can be dissolved in one hour by the use of the Hendryx agitator

as can be dissolved in 24 hours by the usual methods of percolation as somewhat misleading, and explains that in the Hendryx 18-ft. agitator only about 35 tons of mixed sand and slime is agitated during 7 hours, while in every day practice on the Rand, up to 400 tons of sand is treated in 5 to 7 days including the subsequent operations of transfer of sand, settling, washing, re-settling, and emptying of the treatment vat which are not included in the 7 hours mentioned as required by the Hendryx agitator. Mr. Stadler considers that figures relating to the costs should also have been supplied, and goes on to express regret that the results of various tests made by the Mines Trials Committee, particularly those relating to tube milling made during the last three years do not appear. The apparent reason for the non-publication of the results of the tests made by the Mines Trials Committee is the desire that they should only be available to those contributing to the cost.

Progress in the Joplin District

Extensive development in all districts has brought old mines back again. While there is more or less new development, and new fields are producing a portion of the heavy shipments that are going out of the district, old ground is likewise playing a conspicuous part in the era of renewed activity. From the New Century Zinc & Lead Co.'s land at Galena, Kansas, heavy production is being made, and it is interesting to note that this ore comes, not from present-day mining operations, but from old dump piles that were discarded as worthless by pioneer operators who could mine only the richest ore at the prices which then prevailed. This is only one instance of many similar ones. In the Galena district, especially, where numerous shallow hand-jig operations were conducted, rich boulder heaps accumulated, and the re-working of these is now netting a profit to the operators.

Higher ore prices make it possible for mining companies to handle thinner ore, and as a result the demand for sand jigs and slime tables has been heavy recently. New tables have been installed at the Wilson mines at Duenweg, Missouri, at the Harmon mill, Galena, Kansas, and at many other plants throughout the district. Clean-ups from slime tables now command a fairly good price, and much of the fine ore that formerly was wasted is now finding its way to the smelters.

Dvelopment of exceptional importance has been launched by O. W. Sparks, of Galena, Kansas, in the old Klondike district, northwest of Joplin. He has constructed large concentrating plants at two new mines, which are known as the Yellow Jacket and the Yellow Pup. Both mines are exceptionally rich at this time, the aggregate production being about 650,000 lb. of blende concentrate weekly. This is a phenomenal output, but whether it will long continue is problematical. The ground in that region is 'poekety,' and just how long a big orebody will continue cannot be foretold. Sparks claims to have drilled the ground thoroughly and to have found ore in many of the holes. Other examples of rich poeket mines, which are holding the limelight in the district at this time for their heavy production, are the Pocahontas, yielding 150 tons of blende per week, and the Sitting Bull, yielding about 175 tons per week. The average mill of the district cleans up about 30 to 40 tons per week.

THE Scott expedition to Baffin Land in search of gold has returned to St. Johns without meeting with success. It reports having discovered enormous deposits of coal and iron, and has brought back the survivors of the Munn expedition. Munn is a British army officer who was in command of an expedition to the same place and on the same errand. He lost his ship in Ponds inlet. It was crushed by ice floes. Munn found gold, but his search was discontinued owing to the loss of his ship. When he was saved, only seven barrels of bread and two barrels of beef remained, and no clothes.

## The Miami Concentrator

\*The new concentrator of the Miami Copper Co. is one of the largest in the world as well as one of the most complete in labor-saving equipment, and it is correspondingly efficient in its operation. The plant is designed to take every advantage of natural conditions, such as the lay of the ground and, at the same time, it has incorporated a most complete conveying system into its design. The importance of the mechanical handling of ore is recognized in all modern ore-treating plants, and most cases the development of the ore deposits would not be commercially possible without the use of conveying machinery. The economy of conveyors lies not only in the great saving in labor, but it also permits accurate sampling and mixing, as well as allowing uniform feeding.

The shaft, crusher building, and storage-bins are all situated on a ridge. In line with the bins and upon the side

ELECTROMAGNET TO REMOVE STEEL FROM ORE.

of the hill is the concentrating plant. Under this arrangement, the ore, during the concentration, is constantly being carried downward by gravity, thus passing through the process with no further necessity for mechanical handling.

Ore is hoisted in  $7\frac{1}{2}$ -ton skips, which are dumped automatically into bins above the crushers. From the bins the ore is drawn out by 48-in. rotary feeders and delivered to two No. 7 $\frac{1}{2}$  gyratory crushers. From the crushers the ore passes upon a 30-in. inclined Stephens-Adamson belt conveyor, 257 ft. between centres of end pulleys. This conveyor rises in an inclined gallery to a point above the storage-bins, where it discharges upon the horizontal distributing conveyor. This is necessarily of the same width and capacity, and is 329 ft. between centres. This conveyor is carried horizontally in a gallery above a row of six cylindrical steel storage-bins of 1000 tons capacity each. The conveyor is equipped with an automatic tripper, traveling back and forth on a track along the conveyor line and serving the various bins through openings in the gallery floor.

On delivering the crushed ore to the concentrator for treatment, a separate conveyor leads from each bin to the plant. An automatic disc feeder and sampler regulates the feed from the bin to the conveyor and, at the same time, it is arranged that of the ore delivered by every fifth revolution of the feeder disc, a small percentage is automatically diverted as a sample. Under this arrangement, an analysis of the ore may be made at the time the ore is delivered for treatment and the nature of the treatment is thus de-

termined. The conveyors, leading from the bins to the concentrator, are each 14 in. wide and 24 ft. between centres, leading directly to the reducing rolls in the concentrator building.

As a protection for the reducing rolls, a power electro-magnet is suspended above the first conveyor, which removes all scraps of iron which have become intermixed with the ore. This is a precaution which should be taken in all cases where bits of iron or tools dropped by the workmen are apt to get in the ore, cause serious damage to the crushers or rolls, and consequently delay to the entire plant.

On account of the high position of the plant, it was not practical to place the concentrate-bins near the plant and to bring the railroad to them. The method adopted was to place the bins a considerable distance from the concentrator at a level more easily accessible by the railroad. In order to supply the bins under this arrangement, it was necessary to construct a long tunnel through which the concentrate is delivered from the plant to the bins.

The general construction of the concentrator buildings is concrete, steel, and corrugated iron. In this connection, a feature which immediately strikes a visitor to the plant is that all buildings and galleries are absolutely and scrupulously clean. This is a feature which is more easily possible in this plant than in those where the material handled produces a quantity of dust, but nevertheless the result is attained only by means of a certain amount of work, and the contrast presented to other plants is very pleasing. The various levels of the concentrator are connected by iron stairways for the convenience of guests and employees, and all parts and equipment of the plant are easily accessible.

Electric drives are used throughout the plant, the power being generated in the company's own power-plant. This is near the loading bins, beside the railroad, so that fuel is easily supplied. The building and equipment of the power-station are also thoroughly modern and efficient and in keeping with the character of the main plant.

The capacity of this concentrator is 3000 tons of ore per day. The concentrate is all shipped to the Cananea smelter, at Cananea, Sonora, Mexico. At this Cananea plant there is also a system of Stephens-Adamson conveyors for bedding and reclaiming the concentrate and delivering it to the roasters. This system was illustrated and described in the *Mining and Scientific Press* of May 4, 1912.

The Miami plant was designed and constructed under the supervision of H. Kenyon Burch and is now operated under the management of B. Britton Gottsberger, general manager for the Miami Copper Co. All conveyors for this plant were furnished by the Stephens-Adamson Mfg. Co. as well as a large amount of the equipment used in the concentrator, including over one hundred conical settlers.

## Lead Production in 1911

The final figures of lead production in the United States in 1911, just issued by the United States Geological Survey, shows an output of 486,976 short tons of refined lead, which is 16,596 tons ahead of the best preceding record—that of 1910. Missouri was the largest producer, furnishing nearly 45% of the domestic pig lead. The growth of the lead industry in the United States in recent years has been continuous and rapid, as is shown by the following figures:

### PRODUCTION OF REFINED LEAD IN THE UNITED STATES, 1880-1912

1880	97,825
1890	161,754
1900	377,679
1910	470,380
1911	486,976

The total production of lead since the beginning of mining has been 10,040,704 tons. In 1911 the gain in lead production was made wholly by domestic lead, the output of foreign lead smelted or refined in this country having decreased 14,419 tons.

\*From *The Labor Saver*.

## Natural Circulation of Cooling Water

At the mines in the vicinity of Battle Mountain, Nevada, the scarcity of water has made it necessary to use it as sparingly as possible. The water is made to circulate through the jackets of the gas-engine and compressor naturally, thus eliminating the trouble and expense of pumps. A large water tank is placed beside the engine and beside the compressor. The water enters the cooling jackets at the bottom. It quickly becomes heated, and as it conse-

ARRANGEMENT FOR CIRCULATING COOLING WATER.

quently becomes lighter in weight it rises from the jacket up through the discharge pipe and enters the water tank near the top, the water-level being always kept above the discharge.

## Goldfield Consolidated Report

During September 1912 the total production of the Goldfield Consolidated Mines Co., Reno, Nevada, according to the report of J. F. Thorn, general superintendent, "was 29,752 tons, containing \$433,938, or an average of \$14.58 per ton, of which 28,800 tons was milled with an average extraction of 89.52%, and 952 tons was shipped of an average value of \$22.38 per ton, the net recovery from all ore being \$13.13 per ton. The total net realization was \$200,833, or \$6.75 per ton. During the month 4612 ft. of development work was performed. The total cost of mining, development, transportation, milling, office and general expense was \$6.45 per ton, distributed as follows:

Mining (including stoping and development).....	\$3.78
Transportation .....	0.11
Milling .....	1.98
Marketing .....	0.05
General expense .....	0.48
Bullion tax .....	0.02
Marketing ore shipped.....	0.13
<hr/>	
Total cost of operation.....	\$6.55
Miscellaneous earnings .....	0.10
<hr/>	
Net cost per ton .....	\$6.45

Several discoveries of considerable importance were made during the month. In the Combination mine the 136 BX stope on the second level was considerably extended and produced 700 tons of ore that averaged \$18 per ton. The 136-T raise through the western extension of the 136 orebody disclosed ore, and 150 tons, averaging \$32 per ton, was mined. The 246-C, between the third and fourth levels, 450 ft. east of the shaft, produced 237 tons of ore averaging \$140 per ton. While not very large, this orebody will produce several hundred tons of good ore. The 414-C raise produced 76 tons of \$31.20 ore. In the Mohawk the No. 3 stope through the Sheets-Ish workings produced 3258 tons of ore averaging \$12.20 per ton. The 170-stope on the 250-ft. level, and under the Sheets-Ish orebody, produced 1395 tons of ore averaging \$15.40 per ton. The 348 stope,

between the third and fourth levels, was extended south and produced 340 tons of ore averaging \$90 per ton. The 490-R sill being cut on the intermediate, between the third and fourth levels, and about 200 ft. south of the 354 stope, produced 611 tons of ore averaging \$100 per ton.

In the Clermont the downward extension of the 510 orebody in 571 drift, between the 900 and 750-ft. levels, produced 36 tons of ore averaging \$38.20 per ton. The 700-F stope, between the 1200-ft. level of the Grizzly Bear and 1000-ft. level of the Clermont, produced 448 tons of ore averaging \$42.40 per ton. The 603 stope, between the 1000 and 900-ft. levels of the Clermont, produced 329 tons of ore averaging \$26.20 per ton. The 802 stope on the 1300-ft. level produced 302 tons of ore averaging \$25 per ton. In the Jumbo No. 2 the 220 drift on the 200-ft. level was extended 100 ft. north, through ore that averaged \$50 per ton over a width of 5 ft. A raise in this orebody produced 100 tons of ore averaging \$72.80 per ton. On the 300-ft. level the south drift is being extended to connect with the downward extension of the 220 orebody. In the Red Top the raise through the 115 orebody from the No. 1 level has been extended to the surface, and a glory-hole started, which produced 1150 tons of ore averaging \$25 per ton.

The estimated October production of the company is as follows: total tons mined, 30,442; gross recovery, \$401,000; operating expenses, \$185,000; net realization for the month, \$216,000.

## Portable Suction Rose

This is a useful acquisition to the clean-up outfit for pumping the solution out of the extractor-boxes. It is inserted into the down-take compartment and the suction hose is put inside when pumping out solution during the clean-up. As a general practice a piece of screen is im-

PORTABLE SUCTION ROSE.

provided as a rose by wrapping and tying it to the end of the suction hose, which generally annoys the operator because of its confined area getting choked.

With the rose shown in the illustration it will be seen that the screen area is comparatively large and the end of the hose is free, being supported on a wire frame. The funnel is made of stout galvanized iron large enough for the hose to slip in easily, the dimensions of the one described being 3 ft. long, diameter of pipe 3 in., size of rose 9 by 12 in. with a screen area of 48 sq. in. Mill screen say 25 mesh may be used, is easily soldered on the frame, and lasts about 12 months.—*Jour. Chem., Met. & Min. Soc. S. A.*

COPPER production from Alaska in 1911 was 22,314,889 lb., as compared with 4,311,026 lb. in 1910. The large increase in the output for 1911, according to the United States Geological Survey, is due to the entrance of the Copper River district into the producing list. The mine production of copper for 1911 was 27,267,878 lb., but a considerable portion of this had not been smelted at the close of the year. Important production of copper from Alaska began about 1903, since which time it has been a steady contributor of that metal. To the close of 1911 the total production of blister copper has been 59,126,334 pounds.

## Discussion

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment. Insertion of any contribution is determined by its probable interest to the readers of this journal.

### Pacific Smelting

The Editor:

Sir—My attention having been called to a brokers' circular stating that the Pacific Smelting & Refining Co. (meaning the Pacific Smelting & Refining Co.) has signed a contract for the treatment of its ores, and that shipments will begin on November 1, I hasten to say for the benefit of those whom it may concern that said statements are premature. As consulting engineer for that company and as president of its Mexican subsidiaries, I have been investigating the possibilities of doing what has been erroneously announced as a *fait accompli*. The physical position of the company is excellent, and under certain circumstances, involving some further capital expenditure, it can shortly enter the ranks of the producers. When this end may be in sight, due notice will be given by the officers. I make this statement now in vindication of my own position.

COURTENAY DE KALB.

Tucson, Arizona, October 19.

### Hydrometallurgy of Copper

The Editor:

Sir—In your issue of September 14, in a review of W. E. Greenawalt's 'Hydrometallurgy of Copper,' you find fault with the amount of space Mr. Greenawalt has devoted to roasting. In this I do not agree with you. The entire success of most wet processes for copper depends upon the preliminary roast. The lixiviation part of the program is difficult enough, anyway, but is rendered almost impracticable if the roasting has been improperly conducted. Hence, roasting is the key to all subsequent treatment, and demands the most minute study and attention. It is just enough dissimilar to the ordinary careless roasting for smelting purposes to require the most careful differentiation, and I esteem the portion of his book that he has devoted to this subject as the most valuable part of the entire work.

As regards the portion devoted to lixiviation, I think I may say that no man living is competent to write a satisfactory manual on this subject, for the simple reason that no man has yet practised satisfactorily a considerable number of the more important of these processes upon a commercial scale. Consequently, the personal element is lacking, and this is what is needed to make such a book readable, convincing, and authoritative. Failing this impossible requirement, I think that Greenawalt has given us the best book on the subject that we have as yet.

EDWARD D. PETERS.

Dorchester, Massachusetts, October 22.

When reviewers, or doctors, disagree, it not uncommonly results from a concentration of attention upon different phases of the topic. That the special features of roasting preparatory to lixiviation deserve careful attention and study, no one can deny; and it would have been well to devote even more space to pointing out exactly in what way roasting for this purpose differs from ordinary roasting and what variations in construction and operation are necessary to ensure successful work. Mr. Greenawalt has given much of this, but it is obscured in a mass of material treating of the general principles of work, and the ordinary metallurgist is unable, without much study, to pick out what is significant from what is not. It is obvious, of course, that the type of book most useful and interesting to an engineer does not necessarily coincide with the one most

interesting to the distinguished professor of metallurgy in Harvard University, who can at once see for himself the significance of the data presented. The ordinary engineer who is endeavoring to solve his own problems will be grateful if the data is discussed by the author from the standpoint of its significance, thus relieving the reader of work which he is often ill qualified to perform. For this reason, I believe it would have been better if the author had curtailed his discussion of the general principles of metallurgical work and had discussed in more detail those special principles and features which are peculiar to this field of work. It is safe to assume that practically everyone who reads this book with care and attention will previously have read with equal care and attention several or perhaps all of the standard treatises on metallurgy. It would seem safe, then, to presuppose this knowledge and concentrate upon what is new. If the hammer falls on your thumb as well as the nail, its useful work is lessened, and, conversely, if the mental energy of the reader is concentrated upon what is significant and useful, he secures the highest intellectual efficiency. Modern life demands the maximum of useful result from the minimum of effort, in the field of literature as well as elsewhere, and, for example, such a novel as Manzoni's 'I Promessi Sposi,' if it were rewritten nowadays would probably be condensed into the compass of a short story. The same considerations apply to technical literature with even greater force. In our basal views, Mr. Peters and myself are in essential agreement, we merely consider the matter from a different point of departure. It is unnecessary to add that Mr. Greenawalt has given us a highly useful treatise, since otherwise it would not evoke such an amount of critical attention and comment.

THOMAS T. READ.

San Francisco, November 4.

### Sticking to the Job

The Editor:

Sir—In your issue of October 19, I read with glee the pictographic communication from Señor Don Joven de Todos Lugares. His ability to accent the humor of the condition confronting callow graduates makes more clear to the engineer possessed of an insight into the mining the overmanned state of the profession today; a state recognized by your editorial of October 12 remonstrating against the establishment of new and scantily equipped mining schools, such as that in Weir City, Kansas.

Not to dilate upon this matter unduly, I will only say that to my personal knowledge three mining engineers of a number of years standing have engaged in the automobile and automobile supply business in the United States, one coming from Mexico City. Another, after a personally successful mining career in Mexico (state of Chihuahua) has given it up almost entirely to engage in lumbering in California. A fifth is manager of a citrus fruit exchange in southern California. A sixth has found real estate and building operations in Los Angeles more attractive than squinting through a transit or putting his *firma* on pay-checks down in Velardeña, Durango.

A multiplication of such instances would be easy, but although furnishing supplementary proof of the exceedingly long and hard row of stumps in which the young graduate engineer finds himself, would no doubt annoy those among your subscribers who adhere to E. P. Mathewson's views on this subject; hence, I hope the space thus saved will be filled by communications from them. I cannot refrain, however, from pointing out that this condition is not confined to North America, as an Australian acquaintance, a graduate of the School of Mines at Adelaide, South Australia, has assured me that a great many of his classmates there were 'going on the land' in West Australia (the equivalent of homesteading in the United States) and raising golden wheat at a greater profit than from seeking golden metal, apparently.

SONORENSE.

Yzabel, Sonora, October 23.

### CHIHUAHUA, MEXICO

THE MINING SITUATION.—DEPREDEATIONS BY REBEL BANDS.  
—THE OUTLOOK FOR QUIET.

The situation continues to be one of great uncertainty for the mining interests. The Mexican Northwestern railroad is out of commission north of Pearson, thus cutting off the mines of western Chihuahua from direct communication with the United States, and stopping shipment of American coke and coal for the smelters. The old Central line is not yet repaired, there being a length of about 40 km. to rebuild. Rebel bands infest the country on both sides of the line and it is believed that as soon as an attempt is made to open the road they will put it out of commission again. In fact, several of the new bridges have

MAP OF CHIHUAHUA.

already been burned. On the night of October 20 a band of rebels entered Terrazas, 25 km. north of here on the Central line, burned the temporary station and the box cars, burned the pumping plant of the Rio Tinto Copper Co. (thus compelling a shut-down of its smelter), robbed the company of \$3700 and goods to the value of \$1400, and committed minor depredations on the homes of the people and retired to the hills with the plunder. This in spite of the fact that a guard of Federals had been there at about noon of the same day. No attempt seems to be made to pursue or capture these bands. There are numerous bands of this character around Chihuahua, and any outlying property is liable to be looted at any time. It is said that the Rio Tinto company will resume only on condition that an adequate guard is placed there to remain until danger is over. The A. S. & R. Co. smelter is running steadily, as are the mines of the Santa Eulalia district. In western Chihuahua the Dolores is still running or trying to, the Yaquivo Development Co.'s mill is closed, the La Republica is flooded and shut down, the Sierra Mining Co. is simply sending forward the machinery already at the railroad terminal, while the Concheno is getting in and erecting equipment already on hand, while working up the old slime dump. The general attitude exhibits a reluctance to let go, as long as there is a chance to continue work, but everyone realizes that the present conditions, if persistent,

must result ultimately in closing all mining operations, as nothing can be regarded with certainty. The fact is generally recognized that the present government is deplorably weak and has lost the confidence of all. Even the support of the army is half-hearted, and should the right man show up, the strong man capable of wielding the big stick, it is pretty certain that the people of Mexico, army and all, would flock to him. If Mexico only had a Theodore Roosevelt.

### FAIRBANKS, ALASKA

WORK ON ESTER CREEK.—RUN AT THE SPALDING MILL.—  
NEW MILLS ON CHATHAM CREEK.

Erection of the 2-stamp Nissen mill brought in by Hudson Bros. is practically completed. The mill is situated on Ester creek, where a good supply of water is available the year around. As the new working shaft will not be able to produce much ore before the first of the year, it is the intention of the owners to do such custom work as is bound to come from the numerous quartz prospects around Ester Dome. As transportation is a large item in milling costs, the mill will be a great help to those prospecting in the vicinity. An option for \$10,000 has been taken on the vein owned by Neil & Ballaine at the head of Sheep creek. A shaft is now being sunk on the claim. Some very promising ore has been taken from the outcrop of this vein. O'Malley Bros. have bought a quarter interest in the lode claims staked and owned by Oscar Haines and Hudson Bros. at the head of Sheep creek, on the saddle between Sheep and Nugget. A small rich vein has been traced for a claim length, ore from which should average several hundred dollars per ton. It is almost impossible to take a sample from the vein that will not show coarse gold. While no mill-run has been made, the owners are highly elated over the showing. The find that led to the discovery of this vein was a 2-ton boulder of white quartz that has one side dotted with remarkably coarse gold.

The little 250-lb. 3-stamp mill belonging to Capt. Spalding, at the head of Dome creek, has made a remarkable showing for the summer, considering the insufficient supply of water and small capacity, as \$10,000 has been produced since its erection, the last 45-hour run netting the owners a bar worth \$2100. It is believed that the little mill could not possibly crush over five tons in that time. The ore is showing a better gold content and the vein is widening in depth. A 2-stamp Nissen mill will be erected in the spring. The Newsboy mill has been moved to its permanent position on 11 Above Cleary and will be crushing again in a few days. The work of rebuilding has been much hindered by the non-arrival of the cement for the mortar-block foundations. Louis Golden is general manager at present. Since the construction of the new electric plant sinking has been started on the Rhoads-Hall mine on Bedrock creek. An electric hoist and pump have been put in and three shifts will rush the winze and open a new level. The mill is crushing steadily and making very satisfactory returns. While Mr. Rhoads is outside this winter Mr. Hall will be manager at the mine. Allan Cunningham has been put in as superintendent of mine and mill.

The 4-stamp mill belonging to Burns and McIlroy is crushing steadily on Chatham creek, the ore production being greater than the capacity of the mill. A good grade of ore is being milled with very satisfactory returns. As yet no concentrating table has been installed, the intention of the owners being to put one in later. At present there is an 8 months reserve of ore in the mine. The Willis & Larson 5-stamp mill is on the ground ready for erection. The millsite is very close to the Burns-McIlroy mill, an abundance of water being assured for both plants. Mr. Willis has some very high-grade ore sacked for the initial run, the intention being to pay for the mill with the first clean-up. A lease on a portion of the Jupiter-Mars has been taken by Brown & Green and a vein of good ore is being developed. A large sample taken across the vein recently assayed close to \$200 per ton.

Horton and Solomon are at present putting up a 2-stamp

mill at the head of Wolf creek. A large amount of good ore has already been blocked out by the owners, as the vein widened considerably as the adit was driven into the hill. The first few runs should pay for the mill. Competent judges put this property in the front rank of promising prospects. An ideal millsite is one of the assets of the owners. Near this property, Gus Balzimer is still cross-cutting to intersect the vein found on the surface. The cross-cut is in over 600 ft. and so confident are the owners that they are near the vein that one of the partners is now outside negotiating for a mill. If intersected at more than 700 ft. from the portal of the adit there should be 400 ft. of 'backs' at the face.

### JOHANNESBURG, TRANSVAAL

#### DECREASED AUGUST OUTPUT.—WORK OF PRINCIPAL COMPANIES.

Although August contained the same number of working days as July, the gold output for the Rand for August shows a decrease of 377½ oz., in value £15,901 when compared with the preceding month. But this decline is of no significance, and is more than accounted for by the Crown Mines decrease of £23,099 in the value of the output, caused by the transition of mining operations in connection with the concentration scheme at that property. This operation has not only affected the total value of the gold output of the Rand, but temporarily placed the Crown Mines in the third position among the producing mines of the Rand instead of the first position as formerly. This cannot last long, and unless the Randfontein mine can bring more of its idle stamps into operation the Crown Mines will probably soon take the position of the premier producing gold mine of the world, and maintain that position with greater ease than in any previous period of its history. Knights Deep has had 20 stamps put out of operation, due to the destruction by fire of the crushing plant, and its August output fell off to the extent of £9281. The mines controlled by the Consolidated Gold Fields of South Africa accounted for a considerable proportion of the fall in output, and we must look to the following increases over July, Village Deep £9464, New Modderfontein £9315, Randfontein £7612, Bantjes £3059, as showing perhaps more correctly the gold output tendencies of the Witwatersrand, and this in face of a decrease, as compared with July, of 3814 natives employed in the gold mines. The total gold production of the Transvaal during August was 764,737 oz., valued at £3,248,395, to which the mines situated outside the Witwatersrand only contributed £138,219, leaving the Rand with an output valued at £3,110,176. Those companies producing over £100,000 per month are given below, along with their respective equipments and results:

	Stamps	Tube-mills	Tons crushed	Value
Randfontein	700	29	206,037	£265,585
East Rand Proprietary Mines	820	25	153,650	254,783
Crown Mines	660	25	158,600	246,738
Ferreira Deep Deep	225	6	51,440	105,505
Robinson	250	6	51,200	102,489
	2655	91	620,927	£975,100

It may be pointed out that at one time the Robinson mine occupied the position of the premier gold producer of the Rand, but has now to be content with fifth position, all the producers by which it has been superseded being the result of amalgamations rather than increased capacities. Eighty stamps scattered over the Rand were hung up in August as compared with July, but 25 others were dropped, leaving a net decrease of 55, while 254 tube-

mills were at work as against 261 in the previous month. One feature for congratulation in the August returns is the fact that group profits were £1,028,515, as compared with £1,018,880 in July, a feature all the more welcome when it is remembered that, despite the steady increase in the production of gold on the Rand, profits and dividends have for some time declined. It is to be feared, however, that even this small increase of group profits, amounting in all to no more than £10,000, does not speak as well as it ought for the mine; for at the last meeting of the Chamber of Mines the president estimated that the reduction in the carriage of coal by rail to the gold mines which came into force on August 1. would mean a saving to the gold-mining industry of £200,000. Surely such a saving ought to be represented in increased profits to a far greater extent than £9635.

### LONDON

#### RESULTS AT THE CAUCASUS COPPER.—SUCCESS AT ZAAIPLAATS.

The Caucasus Copper Co. has had a long fight for existence, and immense sums have been spent on the mine and smelting works, much of it to no purpose. The venture is of interest to Americans, as a large amount of the money was provided by the J. P. Morgan group, while James Colquhoun, once manager of the Arizona Copper Co., came to the rescue in solving the mining and concentration problems, and W. R. Van Liew, once of Butte, reorganized the smelting plant. Things seem to be brightening now, and prosperity is in sight. The property is near Dzansul, in the Russian Caucasus. The report covering the year ended May 31 last (Russian style) shows that the production was equivalent to 3030 metric tons of refined copper. The sales brought an income of £256,195, and the working cost was £166,019. Out of the profit, £70,044 was paid as debenture interest, and £23,779 was allowed for depreciation. Mr. Colquhoun is the chairman of the board of directors, and spends a large part of his time at the mine. At the meeting of shareholders he gave many details of the operations. The concentration plant is at present treating 500 tons of ore per day. A third unit of 250 tons capacity is being erected and should be at work early in 1913, while the order has been given for further plant that will bring the daily output to 1000 tons. A new aerial tramway is being built, having a capacity of 2000 tons per day. The methods of mining have been revised. In the first place, the overburden, consisting of loose soil varying in thickness from 10 to 100 ft., is now removed by hydraulic mining; second, the ore is mined from the great open-cut by the 'glory-hole' system, thus eliminating all shovelling. A new reverberatory furnace has been built, measuring 19 by 89 ft., and the waste heat is used for steam production. As regards ore reserve, the estimate seven years ago was 3,600,000 tons, and since then development has about kept pace with extraction. The finances have recently been rearranged. The whole of the outstanding profit-certificates, amounting to £500,000, together with £299,900 in options, have been surrendered and cancelled. The £579,000 6% second debentures have been scaled down to 5%, and £440,000 loans have been satisfied by 5% second debentures. The issued capital of the company consists now of £500,000 ordinary shares, and there are £45,280 5% first debentures, £500,000 convertible 5% second debentures, and £745,900 non-convertible 5% second debentures. The position of the ordinary shares is therefore greatly improved. It will be remembered that the company has the advantage of the higher price of copper ruling in Russia.

Last week I gave some particulars of the tin deposits of the Northern Transvaal and instanced the progress of the Rooiberg mine. The Zaaipplaats is doing even better. Milling commenced in February 1909 and large profits have been made. During the year ended July 31 the mill of 15 stamps crushed 29,330 short tons of ore, from which 1647 short tons of concentrate was recovered, averaging 67%

tin. The average yield was 3.76% of metallic tin per ton of ore. During the year, the 750-lb. stamps have been replaced by new ones weighing 1500 lb. and additional dressing plant has been erected. Re-treatment of accumulated slime is to commence shortly. Developments at the mine continue to be satisfactory. Although the lodes vary in width and content, very rich patches are found here and there. The vertical depth of the workings is now 450 ft. Extensive areas are still unprospected, as also is an alluvial deposit in the valley below. The ore reserve actually blocked out is estimated at 24,622 tons, averaging 3.42% metal; not including ore in branch veins. The accumulated sand and slime awaiting re-treatment amounts to about 60,000 tons. Power is generated by suction gas, and is distributed electrically. During the year, the income from the sale of concentrate was £159,680, and the profit was £108,364. Out of this, £90,000 has been distributed as dividend, being at the rate of 150% on the capital, £60,000, and £14,397 has been spent on new plant.

### MELBOURNE, AUSTRALIA

THE BARRIER'S AUGUST OUTPUT.—LABOR IDEAS OF LEGALITY.—VICTORIAN MINING BILL.

The greatness of the New South Wales silver-lead-zinc field, which is known sometimes as Broken Hill and sometimes as the Barrier, is being further exemplified. Its August output amounted to 25,362 tons of silver-lead concentrate. The actual value cannot be given, but the net mine value, which is very much below the actual and excludes the value of copper, tin, and gold, runs to nearly \$1,900,000. The one drawback at present is the want of men to enable the mines to produce the quantity of which they are capable, and so take full advantage of present prices. They could employ some hundreds of men more.

OPEN-CUT AT BROKEN HILL.

It is indeed a marvelous field, and should be good for many years.

The Australian mine-worker is an extraordinary person. After the recent trouble between the Mount Lyell company and its employees an agreement was made settling the rates of pay for workers and conditions of employment. A ballot is now being taken among the employees to ascertain whether they wish the agreement canceled, on the score that the company has broken some of its promises. Some of the arguments used are funny enough for musical comedy. One ground of complaint is that the company undertook to pay men working in the open-cut \$2.16 per day, and is actually paying them \$2.28. That constitutes, in the eyes of these individuals, a breach of the agreement. One does not usually regard a working miner as a pettifogging lawyer, destitute of scruple; but it is plain that many of the Mt. Lyell men are of this order.

The new Victorian mines bill, the second reading of which was moved on September 11, contains three sections, the first dealing with miners' rights and business licenses, residence areas, leases and licenses, mining on

private land, prospecting, and reserved areas, regulation of employees, mine managers' certificates, and those of engine-drivers and boiler attendants, and a variety of other matters. Part II deals with drainage boards, and Part III with provisions for the abolition of mining boards whose functions have been undertaken by officers of the Department of Mines. If the bill becomes law, the cost of miners' rights will be reduced from \$1.20 to 60c., and the provision is that every agreement for mining in or on private land shall cease at the expiration of the mining lease. Boys under the age of 17 years must not be employed underground in a mine, and boys under the age of 14 cannot be engaged about any mine. Another provision prevents any person from being employed for more than 48 hours in any week as a topman, nor more than eight hours, inclusive of 30 minutes for lunch, in any 24 hours, except in cases of emergency. Eight consecutive hours is the maximum period in which persons can be employed below ground. Clause 36 provides for periodical inspection of mines on behalf of workmen, the provision of water jets or sprays in connection with drills, and this and the following section relate in other respects to the health and safety of the miners. Scholarships are granted for working miners anxious to qualify as mine managers; the restrictions on dredging are increased, the quantity of earthy or mineral substance permissible, in suspension or solution, being reduced from 800 to 500 grains per gallon. Should a company be dissolved, the miners' wages are to be a first charge on the assets. The bill also provides that when a majority of the owners of adjacent mines agree that, in order to prevent an influx of water, action should be taken by and at the expense of all concerned, the Governor in Council may constitute the area embracing the mines a drainage area and a board may be appointed for every drainage area proclaimed.

### BOSTON

FLUCTUATIONS IN BUTTE & SUPERIOR.—PROSPECTS FOR SOUTHWESTERN MIAMI.

That 'variety is the spice of life' holds good in the realm of stock speculations as elsewhere. The antics which the Boston market has been exhibiting in some of the most active specialties during the past few months bears out the old truism. The Hayden-Stone group, which has a large following among both traders and investors, is an example of this. When Butte & Superior was first brought out on the Exchange here by this house, there was a noticeable shifting of speculative accounts from Chino, Ray, and other stocks with which that house is identified, to the Butte issue. This was in anticipation of the steady rise which came with that stock after its appearance for trading. After awhile the wise ones thought they saw Butte & Superior getting top-heavy and they shifted back to some of the less active stocks which were yet scheduled for advances. When the Alaska Gold Mines Co. announcement was made there was for some time a marked recession in Butte & Superior, which could only be attributed to the desire to get into the new issue, which promised quick profits. Still later there was selling of Butte & Superior going on for conversion into Chino, which is in line for an advance, in the opinion of wise ones, because of earnings and dividend prospects. Take the element of speculation out of the market and but very little is left. Not long ago I had occasion to go out to Haverhill, Massachusetts, to meet a few bankers, merchants, and manufacturers who were tied up in a Colorado gold mining investment. I was surprised to find that these grave and reverend gentlemen were giving a large part of their business hours over to watching the New York and Boston stock markets and were nibbling at them all the while. When, in a burst of temerity, I remarked that they were 'dead game stock gamblers,' they showed their pleasure, rather than displeasure; in fact, the soft impeachment was acquiesced in with more or less glee. It is the participa-

tion of people like these, riding one stock awhile and then shifting to another, that makes up a large part of the business of the stock market.

A report from an apparently reliable source states that Southwestern Miami, the youngest of 'the porphyries,' which is now being sponsored by Paine, Webber & Co., has already developed ore enough to pay \$12 per share on the stock. Southwestern Miami is the first property of this kind in which the Paine company has become interested and is being given a good opportunity to prove its merit. Besides the developed ore, which is all on the boundary of the Live Oak, the company has acquired under option on favorable terms additional territory to the extent of 259 acres, known as the Prospectors group, on which it plans to begin drilling. This new group was formerly under option to the Guggenheims for \$250,000, but the option was relinquished by them on the theory that the property did not contain an extension of the ore-zone. The abandoning of their option by the Guggenheims threw the property on the market again on a lower basis, and it was natural that inducements should be held out to the Paine interests to take it over. They are to begin drilling as soon as possible and will have no money to pay out on the option until next March, by which time they should be better able to tell whether they wish to buy or not. Since the Guggenheims relinquished their option the South Live Oak has proved about 70 ft. of  $2\frac{1}{2}\%$  ore within a few feet of the Prospectors boundary line. Southwestern Miami has ample money in the treasury to keep up development work until well into next year. It will be interesting to watch the progress going on in the Miami district for the next few years, both in the old and new divisions, which are of about equal area, as it will show whether the Paine or the Guggenheim organization is better served as to its advices on the territory known as the Prospectors group. Boston thinks—its wish being father to the thought—that the Paine interests, though new to 'the porphyries,' will win out in precisely the same way that they have in the Lake country and in Butte. At any rate, Southwestern Miami has recently gained a couple of points on the development news reported.

### BUTTE, MONTANA

BUTTE PRODUCTION.—EAST BUTTE FLOURISHING.—THE BRADLEY PROCESS.

The mines of the Butte district produced 26,000,000 lb. of copper in October. Of that amount, the two Anaconda smelters furnished 24,600,000 lb. This latter included 2,100,000 lb. of North Butte copper and 493,000 lb. of Tuolumne production. The output of the East Butte was about 1,200,000 lb., including Alex Scott production, and the remainder was contributed by miscellaneous shipments. At the rate of production during the past ten months, an estimate of 49,800,000 lb. for November and December is made, which will bring the total production of the Butte mines for 1912 to 320,850,000 lb., a record for the district. Of this great total, the Anaconda smelters will have turned out 306,350,000 lb., East Butte 13,500,000, and 1,000,000 lb. will represent the small miscellaneous production from ore shipped out of Butte. The two Anaconda smelters and the East Butte plant handle practically all the ore of the Butte mines. Owing to the fact that several of the Anaconda mines have been shut down for a month or two, the report has gone out again that the company had entered upon another period of curtailment, but the fact is that the mines of the company have been shipping more ore than the two smelters have been able to handle. The Buffalo mine was closed for three weeks while repairs were being made to the shaft and the hoisting plant was overhauled, but the mine resumed operation a few days ago. The Buffalo employs about 400 men. The West Colusa has been shut down for two months while the change from steam to air power was made, but when that was completed it was decided to

make some extensive repairs in the shaft and mine, and the property will probably not resume work in another two months. The Original has also been closed several weeks for repairs, which will not be finished for another month.

The East Butte Copper Mining Co. has resumed sinking its shaft and will continue to the 2000-ft. level, which will be 800 ft. deeper than the present lowest working. Some of the best ore yet mined from the property comes from the 1200-ft. level, the average content in copper being about 11%. The largest orebody is on the 800-ft. level, upon which the company has been mining for several years, and the largest portion of it has been taken out on that level. The grade of ore on the 800-ft. level is 7%. Shaft-sinking does not interfere with mining, and the production will be maintained around 1,225,000 lb. per month. The East Butte smelter is operating two furnaces, but plans were made long ago for an enlargement of the smelter. Steel has been ordered and received, but as the work would necessitate a suspension of mining for some time and the company would lose the benefits of the present high copper price, it was decided to postpone the smelter changes. The East Butte owns mining properties at Elkhorn, Austin, and Pittsburg, Montana, besides its 265 acres of mineral ground on the east side of the Butte district, and these are to be developed when the smelter is enlarged.

The success of the Heinzes in New York in getting a jury verdict against the Barnes-King company for money subscribed for stock of the company during the flotation came as a surprise to the officers of the company in Montana. Attorneys for the company in New York say there is no doubt that the verdict will be set aside by the Court of Appeals. The Heinzes claim they bought the stock under misrepresentations by employees of the company, for which they seek to hold the company responsible. The company being made up of stockholders, all in the same boat with the Heinzes, the Western stockholders are wondering what sort of justice there is in New York that prefers the Heinzes over other stockholders in the company and doubly mulets the people who subscribed for the stock by making them pay back the Heinze subscriptions. It was also brought out at the trial that the Heinzes sold part of their stock and want to be reimbursed for the stock they didn't sell and which they still hold, not even having offered to turn it back to the company. The Barnes-King company is pushing work on its new properties in the Marysville district and the Kendall country. Production will be started next month from the North Moecasin property.

The report from Anaconda is that the Bradley system of treating slime by the Bradley-Burrage-Lawson method has so far been a failure. The syndicate from Boston, which promised to revolutionize the methods of copper recovery, spent about \$300,000 in building and rebuilding a plant in which to employ the Bradley process, but they still have faith in the inventor. After several attempts to operate the plant, it has again been shut down and another lot of changes are being made. The Butte & Superior company expects to have its rebuilt concentrator completed in another month. A lot of new machinery has been received and is being put in place. The plant as originally constructed was a failure, and it is yet to be proved that the new plant will make profits for the company. It is stated that the company is still engaged in gathering in other properties under options, which seems to indicate a faith in the country adjacent to the Butte & Superior mines. The last of the machinery for the Butte Central Copper Co.'s mill is on the way, and will be installed by the latter part of the month. It is announced that the mill will be working by the first of December, and that by the first of January the stockholders may expect profits on operations. Western stockholders of the Butte Central regard it as unfortunate that some of the Boston shareholders and the underwriting syndicate have gotten into a controversy among themselves, which is not likely to help the market end of Butte Central.

## General Mining News

### ALASKA

#### FAIRBANKS

(Special Correspondence.)—After a visit of three weeks, in which most of the quartz claims were inspected, P. Smith, government geologist, left Fairbanks on the last boat. Before leaving he spoke in a very optimistic tone of the future of the district in lode mining to the members of the Commercial Club. While Mr. Smith could not give the results of his investigations in full, his observations left a favorable impression on his audience. His paper on the lode mines of the district will be awaited with much interest.

Fairbanks, October 3.

The Teddy R. quartz claim, on Moose creek, a tributary of the Fairbanks, has been bonded to G. Wheeler for \$100,000. The property is between the claims of Crites & Feldman, who have good prospects, and have uncovered two parallel veins about 12 in. wide each for 500 ft. in length, and the Teddy R. lies between these claims. The dredge on Mastodon creek got into frozen ground and has been shut down for the winter. A thawing plant will help operations next season. The steamers *Tanana*, *Delta*, and *Reliance* have been docked for the winter.

#### IDITAROD

It is stated that the Guggenheim dredge, on Flat creek, is doing remarkable work, and the average daily yield is \$18,000. Weather conditions have been favorable, and work may be continued longer than was expected.

#### JUNEAU

During September the 120-stamp mill at the Alaska Mexican mine worked 29.70 days and crushed 19,593 tons of ore yielding \$24,823 in free gold, and \$30,088 from 379 tons of concentrate. Operating expenses were \$26,998, and construction \$4066, leaving a net profit of \$23,296. Development covered 332 ft. and the stock of broken ore increased 9842 tons.

The two 120-stamp mills at the Ready Bullion and 700-Ft. Claim of the Alaska United worked 29.52 and 29.71 days, respectively, crushing 17,990 and 19,656 tons of ore, yielding \$111,397 from free gold and 964 tons of concentrate. Operating expenses were \$52,232, and construction \$6831, and the net profit was \$52,334. There was 187 ft. of development done in the Ready Bullion, and 313 ft. in the 700-Ft. Claim, and the stock of broken ore increased by 4933, and decreased by 110 tons, respectively.

#### NOME

(Special Correspondence.)—The Nome Montana dredge shut down for the winter on October 14, and others are following suit on account of the recent freeze-up. All sluicing operations are also stopped for the season. C. T. Merson has taken options on some claims on Solomon river, and has two drills at work prospecting. It is reported that when one of the new dredges on the American river started work recently, the ground was found to be too low grade to pay expenses, so the owners are now looking for workable ground to move the dredge to. In this connection, it is interesting to note the contentions of Charles Janin, in the *Mining and Scientific Press* of September 28, when he stated that dredges were often erected in Alaska before the ground was thoroughly prospected, and this seems to be an instance of such work.

Nome, October 16.

A freight steamer recently carried 16 miners from Candle to Nome, and the company was fined \$1000 for violating marine laws which forbid freighters carrying passengers.

#### VALDEZ

The Bluebird group of six claims, situated near the water on the outside of Shoup bay, have been bonded by D. Anderson and C. Swanson for \$75,000. Considerable work has been done on the property, and a vein over 6 ft. wide, averaging \$12 per ton, has been opened. It can be

traced for 600 ft. on the surface. Being near the sea, a drift can be driven into the mountain and ore handled cheaply.

### ARIZONA

#### COCHISE COUNTY

In the Tombstone district operations at the Tombstone Consolidated mines are being carried on by about 50 lessees, who are shipping ore to the smelters at Douglas and El Paso. Owing to the new miner's lien law, the number of lessees has decreased considerably. Local opinion states that the Tombstone Consolidated company, which is now going through the bankruptcy court of this state, would be sold and work resumed on a small scale next year, but now it is thought that this may be postponed, as a deal has been considered in which the whole property will be leased to well known mining men.

The steelwork of the blast-furnace stack at the Calumet & Arizona smelter is completed. It is 305 ft. high, being 5 ft. higher than that of the Copper Queen. The stack is now being lined. The sample mill machinery is being installed, also 12 Herreshoff roasting-furnaces, and waste heat boilers to utilize the heat from the reverberatory furnaces.

#### MOHAVE COUNTY

The molybdenite mine, owned by Smith, Sawyer & Co., is situated in Copper canyon and Deluge Wash, five miles north of Cedar. Drifts have been driven over 140 ft. on the veins, which are 72 in. wide in parts. About 300 tons of ore is on the dump, and samples return 24% of molybdenite and 3% of copper. The Gold Road company has installed a gasoline hoist at the Jupiter group of claims, and is sinking below the 114-ft. level. Samples taken from a depth of 50 ft. in one of the claims owned by M. Carr, at Cedar, have given high results in silver, over a width of 48 inches.

#### YUMA COUNTY

The dump of tailing, containing about 2000 tons, at the Billy Mack, has been sold to the Humboldt smelter and will be hauled to Parker to be loaded into cars, at a rate of 200 tons per month.

### CALIFORNIA

#### MODOC COUNTY

(Special Correspondence.)—The Modoc Mines Co. has its shaft down 100 ft., and is sinking 100 ft. farther. Fair-grade quartz is reported to have been opened. The sale of the Ft. Bidwell Consolidated mines, by the sheriff, has been

MURDOCK MINE, HIGH GRADE.

postponed. Advice from Detroit is to the effect that the directors have promised to pay off the claims against the company. The Spearmint company is sinking on the Lucky Dutchman lease of the Yellow Jacket. The shaft is over 40-ft. depth with fair-grade ore showing. A. L. Arnold and Colorado associates are chiefly interested. On the Sunshine, the Twin Leasing, Bruner, and other leasing companies are

still working. In most instances operations are proceeding on a small scale.

Ft. Bidwell, October 29.

H. V. Meloy, formerly of Salt Lake City and Ely, has secured a bond and lease on the Dandy property at High Grade, of which district little has been heard of late. After a little prospecting had been done, a 10-ft. quartz lode was uncovered, carrying fair gold content. Mr. Meloy has spent some time in the district during the past summer.

#### NEVADA COUNTY

At the Champion mine, in October, 248, 245, and 262 ft. of drifts was driven on the 1000, 1600, and 2400 north drifts respectively. This is believed to be a record for any mine in Nevada City or Grass Valley, the best previous work being at the Empire mine, where 244 ft. was accomplished, against 262 ft. on the 2400-ft. drift of the Champion. Water Leyner No. 8 air-drills were used during three 8-hour shifts per day. During one week 71 ft. was driven in one drift. One hundred and seventy rounds were blasted, breaking  $4\frac{1}{2}$  ft. per round, which averaged eight holes and 13 tons of rock.

#### PLUMAS COUNTY

An option has been secured on the old Kennebec quartz mine by P. H. Daily. It is situated about  $1\frac{1}{4}$  miles from Greenville, in North canyon. Three veins were cut on the top level, which was driven 600 ft. many years ago; and about eight years ago another level was driven 300 ft. lower than the former, and at 500 ft. another shoot of ore, worth \$15 to \$40 per ton, was cut. There is a good millsite near the lower adit, while water-power and timber are cheap. Samples from the Moonlight creek copper claims have returned gold 0.14 oz., silver 39.66 oz., and copper 18.34%, similar to a sample sent to the Selby works in 1885. The property has been opened by a 64-ft. shaft and 70-ft. drift at that depth. The Providence Hill placer deposits are being worked by ordinary mining methods, the hydraulic method having been abandoned owing to the depth of overburden being too great.

#### SACRAMENTO COUNTY

A contract has been let to the Natomas Consolidated company by the California State Highway Commission for about 500,000 tons of crushed rock for the great highway scheme. This rock comes from the dredges of the district, and the above company has rock-crushing plants at Natomas near Folsom, Fair Oaks bridge, and at Oroville, each having a capacity of 1000 tons per day.

#### SANTA CLARA COUNTY

The owner, C. A. Nones, of the quicksilver mines at New Almaden, has been in San Francisco, and states that he will build a railroad from San Jose to the mines. The annual output of mercury is about 2000 flasks of 75 lb. each.

#### SIERRA COUNTY

At the Original Sixteen to One mine, near Alleghany, a compressor plant costing \$10,000 has been erected, and development is under way at No. 1 and 2 adits. An ore-shoot has been opened in No. 2 adit, which is being driven toward the Tightner property. Sinking will be started in a few days. The present company, consisting of California men, acquired the Sixteen to One in October 1911.

#### TRINITY COUNTY

(Special Correspondence.)—Erection of a plant to recover gold and platinum from the black sand in gravel is proposed. Victor Zachett and William Klink, understood to represent Shreve & Co., the San Francisco jewelers, have recently interviewed local mine operators on the advisability of installing such a plant. The San Francisco men state they have perfected a process for the recovery of gold and platinum from black sand on a commercial basis and are ready to erect a centrally-located plant if operators guarantee the desired quantity of material. The rainy season has resulted in increased activity by the hydraulic mining companies. La Grange, the leading producer in the county, is increasing its force, and the normal number of giants will be

in commission shortly. The Hupp, Union Hill, and other properties in the Weaverville district are also increasing operations.

Weaverville, November 2.

### COLORADO

#### GILPIN COUNTY

The main shaft at the Topeka mine is down 1500 ft. On the 1300-ft. level, the vein averages 2 ft. in width and \$12 per ton. At a depth of 32 ft. the Golden Gate lode shows 2 ft. of ore worth 1.4 oz. gold and 5.5 oz. silver per ton. An adit will be driven to connect with the shaft where this ore was cut. Rich ore has been opened on the 800-ft. level of the Alps mine, on Quartz hill, and 7 cords, equal to about 60 tons, is being treated at the Polar Star mill. The Gilpin Orion shaft is down 265 ft., and high-grade ore has been opened from 200-ft. depth.

#### LAKE COUNTY (LEADVILLE)

Efforts are being made to unwater the down-town district, that is, the Penrose and Coronado shafts, and prospect for carbonate of zinc. Arrangements are being made with lessees for this purpose. About 20 tons of ore is being shipped daily from the Sugar Loaf Consolidated adit, which is being steadily driven into the hill. Twelve men are employed. Lessees at the Ella Beeler tunnel have again opened high-grade lead-silver ore in the lower adit, and are shipping regularly. A fair quantity of native silver is mixed with the ore. At the McRae shaft, Iowa gulch, Cucumber gulch, Modoc, New Vinnie, Lime adit, and other claims, owners and lessees are busy at development or shipping ore.

#### SAGUACHE COUNTY

(Special Correspondence.)—The 6235-ft. development and drainage adit of the Rawley Mining company at Bonanza, has just been completed. The bore is 7 by 8 ft. in the clear, and work was started on May 11, 1911. The primary object at the adit was to cut the principal vein of the Rawley mine at the 1200-ft. level, 600 ft. below the deepest of the old workings. The adit work was completely successful, a 6-ft. vein of good silver-copper ore having been cut 4 ft. from where it was expected. The ore has changed somewhat in character from that found in the upper workings, the lead and zinc having almost entirely disappeared. The total length of the old workings amounts to 7416 ft., most of which is in ore. Little stoping has been done on the property, it having been the policy of the company for the past six years to develop ore, and a large tonnage is now blocked out. The total time taken in driving the adit just completed was 17 months and 12 days, the work having been finished about a month ahead of the estimated time. The country along the course of the adit varied greatly in hardness and friability, it having been necessary to timber a total of 1618 ft. Considerable water was encountered, and about 1000 gal. per minute is now issuing from the portal. In the work of construction, the company consumed 41 tons of 16-lb. T-rail, 38 tons 241 lb. of powder, 33,819 caps, and 51 miles of fuse. An average of 42 men were employed in the work. Messrs. Simonds and Burns, of New York, were the consulting engineers in charge of the adit work, and Will C. Russell is manager.

Bonanza, November 1.

#### TELLER COUNTY (CRIPPLE CREEK)

Recent development at the 1600-ft. level of the Portland has proved a fine orebody, and shipments are going out from this level. Local expectations are high as to the recent sampling of El Paso mine. Although the Cresson management does not publish the results of its work, a long rich shoot of ore has been opened on the 1260-ft. level.

The Cripple Creek district, according to the figures given by the various treatment plants, made a total production in October of 75,476 tons of ore having a gross value of \$1,182,954 and an average value of \$15.67, which maintains the average production so far this year.

The feature of the month was the record run at the Portland company's low-grade mill, which exceeded all pre-

vious records, handling at a big profit a total of 16,240 tons of ore averaging \$3.23 per ton. The figures for the month in detail follow:

Plant.	Tons.	Average Value.	Gross Value.
Smelters .....	3,896	\$65.00	\$253,240
Golden Cycle .....	31,000	20.00	620,000
Portland (Colorado City) ..	9,899	22.00	216,778
Portland (Victor) .....	16,240	3.23	52,445
Stratton's Independence...	10,591	2.92	30,726
Kavanaugh .....	1,700	2.20	3,740
Gaylord (Dante) .....	1,400	3.50	4,900
Isabella (tailing) .....	750	1.50	1,125
Total .....	75,476	\$15.67	\$1,182,954

IDAHO

BONNER COUNTY

The Idaho Gold & Radium Mining Co. owns 1500 acres of ground, consisting of five quartz and 70 placer claims, about five miles from Leonia, on the Great Northern railroad. A dam has been built on Boulder creek, and a ditch 20 ft. wide at the top, 7 ft. wide at the bottom, and 5 ft. deep is being dug by a steam-shovel. This will take the creek water to a penstock, which will be 20 ft. above a power-plant capable of developing 5000 hp. From this plant the water will be conveyed in a flume to another intake, from which it will have a fall of 400 ft. to the giants, by which placer mining is to be done. It is stated that there is 1¾ miles of gravel to be worked on the creek bed, and plenty of fall for the tailing.

IDAHO COUNTY

The shaft at the Colonel Sellers claim, of the Mineral Zone group, has reached the No. 2 level, and a station is being cut. The east drift on No. 1 level has been driven 100 ft. in good ore. Generally the mine is in good condition. At the Mascot mine, the Huntington mill is extracting a fair percentage of the gold and a concentrating table is being installed. Everything is satisfactory at the South Fork, and a 100-ton mill, driven by water-power, will be erected in the spring. Fair progress is being made at the American Eagle, North Star, and Penn-Dixie mines.

SHOSHONE COUNTY

In the suit between the Stewart and Ontario companies, in which the former applied for an injunction to prevent the latter from further mining ore from its property, the Stewart was denied the right to an injunction. This is another case of the law of the apex.

The Bunker Hill & Sullivan company paid, on November 4, dividend No. 182, amounting to \$65,400, making a total to date of \$13,846,350. The Engineering Construction Co. of Spokane will replace the timbers recently burned in the Bunker Hill mine, and other woodwork, with concrete, which will cost about \$7000.

ILLINOIS

CRAWFORD COUNTY

(Special Correspondence.)—Production in the Illinois oilfields is not holding up to consumption, and stored oil is being drawn on at the rate of a tank per day. Maps made by the Geological Survey offer little hope for important extensions of the local field in the Carboniferous horizons; but oil has recently been found in the Trenton below. At present there are three wells drawing oil from that horizon in the old Casey field. A fund of \$100,000 is being raised by the oil companies for joint prospecting of the deeper horizons. It is proposed to expend this money in determining the geologic structure rather than with a view to finding oil immediately. The wells will be drilled under direction of a committee working in co-operation with R. S. Blatchley of the State Geological Survey. The structure once being outlined, it will be comparatively easy and economical to test the territory. Mr. Blatchley's general report on the district has been completed and is about to go to the printer.

Robinson, Illinois, October 27.

MISSOURI

ST. FRANCOIS COUNTY

(Special Correspondence.)—No. 1 mill of the Doe Run Lead Co., after many years of service, was closed on October 26 and milling will be concentrated at No. 3, at Flat River. The old mill was built to handle ore from the original mine at Doe Run, and after that mine was worked out, ore was sent down from the Flat River mines to keep it going, more on account of the people living at Doe Run, than for any other reason. As compared with the newer mills, No. 1 was wasteful and inefficient, and considerable economy will result from the change.

MAP OF MISSOURI.

The opening of a new mine two miles south of Doe Run furnishes employment for the men, as it also marks a considerable extension of the district. The Federal Lead Co. has found disseminated ore near Festus, also some distance south of present workings. On October 24 the magnetic separator plant at the Federal mill was burned, though the loss will be slight. The plant was used for dressing the copper sulphide, which is found in small amounts with the lead ore. All the mines in the Flat River district are working to full capacity, though there is some labor shortage.

Flat River, Missouri, October 27.

MONTANA

CASCADE COUNTY

(Special Correspondence.)—The Florence Mining & Milling Co., recently organized by Duluth capital, has overhauled the Florence mine at Neihart. The new company has installed hoisting and drilling machinery, and has erected new surface buildings and ore-bins. The shaft has been continued to the 500-ft. level, and at that depth ore is being opened. The Great Northern Railway Co. has put in a spur-line to the mine.

Neihart, November 2.

FERGUS COUNTY

(Special Correspondence.)—Finch and Campbell, of Spokane, have permanently closed down the famous Kendall gold mine, at Kendall, after a successful run of 13 years. The mine has paid \$1,500,000 in dividends on an original purchase price, from Harry T. Kendall, of \$400,000.

Lewiston, November 2.

MISSOULA COUNTY

(Special Correspondence.)—The Butler Creek Coal Co. is prospecting the Neocene semi-bituminous coals on Nine Mile creek, west of Missoula. If the coal is found to be satisfactory in quantity and quality, a local market will be found from Missoula west.

Missoula, November 2.

SILVERBOW COUNTY

(Special Correspondence.)—The Buffalo mine of the Anaconda company has resumed work after a three weeks shut-down for shaft repairs. About 400 men are employed at this mine. The new hoisting system at the Original mine is being rapidly installed. The mine should be operating full time again by December 1. The West Colusa mine will be

closed for some time yet. Besides the installation of air hoisting engines, the main shaft is being overhauled, and a head-frame erected.

The combination concentrating and cyanide plant of the Butte Central and Boston Copper companies is something new to Butte. It is about ready to begin operations, and the outcome of the venture is being watched with interest.

Butte, November 2.

#### YELLOWSTONE COUNTY

(Special Correspondence.)—Considerable interest is being taken in oil and gas in the Cottonwood district, 25 miles southwest of Billings. Two companies have been formed, the Yellowstone Oil & Gas Co. with Texas capital, and the Billings Oil Co. with Butte capital. Machinery has been ordered and drilling will be under way before the beginning of next year.

Billings, November 2.

### NEVADA

#### CLARK COUNTY

At the Yellow Pine mine, at Good Springs, the vein has been found beyond the fault, and in 20 ft. of driving has widened from 15 to 78 in., of fair grade. The mine has been opened by a 500-ft. incline shaft, and ore reserves are worth \$700,000. The equipment consists of a 60-hp. Fairbanks-Morse hoist, compressor, and concentrating plant, which showed a production of \$39,000 in September. Dividends of 2c. per share are paid monthly to the shareholders, who are Los Angeles people.

#### ESMERALDA COUNTY

During the quarter ended September 30, the Goldfield Consolidated company has treated 94,145 tons of ore worth \$1,245,861. Operating costs were \$581,923 and construction \$2079, leaving net profit at \$661,859. Dividend No. 17, of 30c. per share, was paid on October 31. The San Francisco transfer agency has been closed, owing to the small amount of business done, and transfers will be made either at Goldfield or New York.

#### LYON COUNTY

Over 40% of the ore smelted at the Thompson plant is mined from the Mason Valley property, the balance coming from customs shipments. During the eight days from October 7 to 14, No. 2 furnace smelted an average of 1019 tons per day, producing 66.3 tons of matte containing 42.32% of copper. A. J. McNab, superintendent of the smelter, has been inspecting the Boston & Montana plant at Great Falls, and probably two Great Falls type of converters will be installed at the Thompson plant. At present no converters are used here, matte being shipped to the Garfield smelter, in Utah.

#### NYE COUNTY

The fire at the sub-station of the Nevada-California Power Co. caused damage of about \$20,000; and the plant will be rebuilt at once. The mines at Tonopah were shut down for about 40 hours. The week's production from all mines was 10,395 tons worth \$259,895.

During October the White Caps company, of Manhattan, treated 1500 tons of ore averaging \$18 per ton, at the Associated mill. Placer mines are doing well in the gulch, taking out gravel yielding over \$10 per yard.

#### STOREY COUNTY

The Mexican company has acquired a controlling interest in the Keyes-Graessler group and the Monte Cristo properties in the Sevenmile canyon, and an aerial tramway will be built from them to the Mexican mill. During the week ended November 2, the mill worked 94% of the time, and crushed 565 tons of ore averaging \$29.82 per ton. The 2300-ft. level yielded 164 tons worth \$66.56 per ton. At the Consolidated Virginia, the north drift on the 2300-ft. level produced 21 mine cars of ore worth \$7.51 per ton. A fault has been cut on the 2500-ft. level of the Sierra Nevada north-east drift, while from the southwest drift 2½ cars of ore worth \$100 per ton and 100 lb. of specimens were mined. No. 6 pump has been removed from Ward shaft.

### WHITE PINE COUNTY

The bullion tax report of the Nevada Consolidated company, as sent to the County Assessor, gives the following details:

Ore treated, tons .....	812,084
Gross yield .....	\$3,297,376
Cost of mining .....	\$534,354
“ transport .....	212,079
“ treatment .....	1,331,419
Net returns .....	1,221,524
Bullion tax .....	25,651

At the McGill plant No. 4 and 5 furnaces are running, and No. 1, 2, and 3 are shut down. No. 2 is being remodeled, and when finished will be 135 by 19 ft. The crown of No. 3 reverberatory collapsed during the strike, when cooling, due to shortage of ore and concentrate. Concrete work for the new roaster stack is in, and bricklayers will be at work in a few days. The centrifugal pump installed at No. 1 and 2 ponds is pumping slime, which is being treated on the Craven tables. Since the strike it is stated that many men have not been reinstated, but C. B. Lakenan reports that “there has been no case of refusal to re-engage any former employee who had quit the service of the company under intimidation, or under other circumstances controlling his individual desires, save only for reported inefficiency.”

### NEW MEXICO

#### LINCOLN COUNTY

The suit between the California Industrial Co. of Los Angeles and the New Mexico Mining & Milling Co., involving title to iron mines near Capitan, in this county, has been decided in favor of the former. These mines were purchased by the Los Angeles people, with the intention of using the ore in their furnaces, while the other company filed placer locations on the property, hence the suit. These large deposits are near coal deposits suitable for coke making and smelting. After spending a good deal of money in investigating the iron properties, the California company will now erect a smelter and produce pig iron.

### UTAH

#### BEAVER COUNTY

A report issued by the Horn Silver Mining Co. for the

MAP OF UTAH.

nine months ended October 1, states that ore sales, etc., realized \$110,107, while mining, freight, and other expenses

totalled \$93,090, leaving a balance of \$17,017, which, added to the previous surplus, makes a total surplus of \$39,608.

#### JUAB COUNTY

The May Day mine shipped 18 cars of zinc ore during October, which will average \$1000 per car. The mine is reported to be opening in a satisfactory way. The Chief Consolidated sent out 10 cars of ore during the week ended November 2, and as soon as the Tooole smelter is able to handle more ore, the Chief company will move a larger tonnage. The electric pumps have been taken out from the 2200-ft. level of the Centennial-Eureka, and that part of the mine will fill with water. It is stated that the pumps meant an expense of \$4000 per month.

#### SALT LAKE COUNTY

The Utah-Apex Mining Co.'s revenue from sales of 82,064 tons of ore, 15,854 tons of concentrate and royalty, during the year ended August 31, was \$654,752, and mining, milling, freight, and smelting totaled \$402,806, leaving a profit of \$251,946, out of which \$85,305 was charged to depreciation. The debt of \$66,102 has been paid and bonds valued at \$45,000 were bought at 10% discount. No important additions were made to surface equipment. Development included 2927 ft. of driving and raising. Reserves are estimated at 100,000 tons, and generally the prospects of the mine are satisfactory.

Conditions at the Utah Copper Co.'s mines are fast approaching a normal state, and on October 31, about 14,500 tons of ore was sent to the mills. It is estimated that the October copper yield will be about 3,000,000 pounds.

The Monetaire company, of the Little Cottonwood district, is suing the Columbus Consolidated and Extension companies, and other persons, for \$500,000, being the value of ore wrongfully mined from the Haskell claim. It is estimated that 25,000 tons of ore was taken out of the disputed ground.

#### SUMMIT COUNTY

It is reported that ore shipments from the Princee Consolidated from January 1 to September 30 were worth \$201,914, and there is \$60,000 worth of ore in transit. During the period mentioned, nearly \$145,000 has been spent on permanent improvements. Shipments for the week ended November 2 were 479 tons from the Daly West, 364 from the Daly-Judge, and 344 from the Silver King.

### WISCONSIN

#### GRANT COUNTY

(Special Correspondence.)—The Grasselli Chemical Co. is about to enter this field as an important buyer of zinc ores, and is negotiating with the Vinegar Hill company. Since the Grasselli has a large business in acid making, it is especially well prepared to handle the lower-grade ores of the district.

Platteville, October 27.

### CANADA

#### BRITISH COLUMBIA

The Granby company shipped 26,104 tons of ore from the Phoenix mines during the week ended October 26, making a total to date for the current year of 993,205 tons. The smelter at Grand Forks dealt with 26,167, and 1,022,043 tons for the year. Shipments of blister copper to the refinery in New Jersey amounted to 18,333,500 pounds.

#### COBALT

The Nipissing has paid its 27th dividend, amounting to \$450,000, making a total of \$9,090,000 since June 1906. On October 1 the surplus account stood at \$1,523,049, consisting of cash \$1,082,000, ore in transit and smelters \$101,204, and ore ready for shipment \$339,372. The new mill is nearly finished. Some interesting samples of dyscrasite, an antimonide of silver, containing 78 to 85% of silver and 15 to 22% of antimony, have been brought in from a group of 10 claims west of Sudbury. During the quarter ended September 30, the Wettlaufer mine produced 195,273 oz. of silver valued at \$125,841, or 64.44c.

per ounce. The ore reserves contain about 341,330 oz. of silver, and the mine has not shown satisfactory results from development of late. Ore shipments during the week ended October 26 were 287 tons, and bullion shipments 53,064 oz., valued at \$33,846. Work has been started at several claims at the Gillies Limit. A French-Canadian syndicate has bought four claims in Gauthier and McVittie townships, owned by three French prospectors, for \$250,000.

#### DAWSON

A. N. C. Treadgold, who is greatly interested in numerous properties in this district, has begun the construction of a large ditch on lower Dominion creek, for the purpose of supplying water to sluice overburden from the claims, which will be afterward worked by dredges. The work will require the expenditure of a large amount of money. The autumn has been very mild and it is thought that the Yukon may not freeze over. The average temperature for September was 45°F., ranging from 18 to 74°.

The *Dawson Weekly News* discusses the winter mail service for the Yukon and considers that they are not getting proper treatment in the matter. Dredges in the Forty-mile district have had a good run this season. The dredge on Walker's Fork is to be taken over the hill by teams to Miller creek, as soon as sleighing becomes favorable. About 14 men will be prospecting on the Britannia and Canadian creeks during the winter. Prospects are encouraging, and the gravel on the latter creek is 150 to 250 ft. wide, while the average depth on both creeks is 14 ft. Work has been done by open-cut. The gold recovered assays \$17.50 per ounce. News of rich placer gravel on Walhalla creek has come into Dawson lately, and many claims have been staked.

#### PORCUPINE

The power-plant at Waiwaitan Falls will probably be ready for trial by November, and the mines should receive power about 30 days later. The Vipond management finds that plain amalgamation will not give a high extraction on its ore, so a cyanide plant is to be erected. The Merrill process of direct treatment in presses, without agitation, will be experimented with. Operations have been resumed on the Deloro claim of the Porcupine Consolidated company, and contractors are sinking a shaft on one of the veins in the property.

### MEXICO

#### CHIHUAHUA

The Helena mine, situated in the Cusihiuriachic district, is shipping ore to the smelters. C. F. Sturtevant has been appointed superintendent. La Fe mine, situated at kilometre 105 on the Orient road, has five cars of copper ore ready for shipment.

#### JALISCO

During September, El Favor Mining Co. shipped 267 tons of ore to the smelter and milled a similar quantity, the total yield being ₧48,813. Operating expenses were ₧26,496, and profit ₧22,317. The mill lost 58% of the available running time through accidents. Work has been started on the east side of El Favor mountain, where a vein was cut on the Constancia claim. The September output of the Mololoa company was valued at ₧28,942, and profit only ₧3543, due to heavy development expenses. The Amajac company is resuming work at its Refugio and Las Animas mines, in the Hostotipaquillo district, and will erect a cyanide plant. W. J. Pentland, formerly with the El Oro company, at El Oro, is general manager. A good deal of development has been done, and experimenting on old tailing in the Amajac patio; but the revolution has hindered general operations.

During September the Esperanza mill worked 27 days and crushed 7891 tons of ore, and treated 11,402 tons of tailing, while 203 tons of concentrate was sent to the smelter. The total yield was valued at \$115,168, and expenses were \$89,050, leaving a profit of \$26,118, of which \$2500 was spent on construction and London expenses. Development covered 685 feet.

## Personal

Professional men are invited to send news of their engagements and travels. Such news is interesting to friends.

S. H. BALL is in Nevada.

C. E. VIRDEN is here from Butte.

ALBERT BURCH has gone to Arizona.

H. P. HENDERSON is in San Francisco.

JESSE POUNDSTONE was in town recently.

GEORGE E. FARISH is in British Columbia.

H. FOSTER BAIN has returned from the East.

CHARLES KIMBALL has returned from Alaska.

C. A. NONES has returned from Calaveras county.

LIONEL LINDSAY is on a six weeks trip to Arizona.

C. F. TOLMAN has returned from the Coeur d'Alene.

EDMUND JUESSEN has returned from the Southwest.

D. M. SHANKS was in San Francisco during the week.

A. Y. SMITH has returned to Salt Lake City from Pioche.

J. P. HUTCHINS has been examining mines in northern Finland.

GELASIO CAETANI is in the Southwest on professional business.

C. W. PURINGTON sailed from New York for London on November 6.

KIRBY THOMAS has returned to New York from a visit to Sudbury, Ontario.

H. E. SYMONS has returned to Semipalatinsk in Southern Siberia, from Nicolaievsk and Vladivostok.

E. M. WILKINSON has returned from Tuolumne county and will be near Fallon, Nevada, for a month.

W. W. TISER, who has been prospecting alluvial ground on the Lower Amur, Eastern Siberia, is returning to San Jose, California.

W. S. KEITH has severed his connection with the F. B. Keener mining companies and will open an office as consulting mining engineer at Dutch Flat, California.

The following members of the American Institute of Mining Engineers were in attendance at the meeting at Cleveland, October 28: ROBERT ABBOTT, M. A. AMMON, A. ARLUCK, A. O. BACKERT, H. FOSTER BAIN, H. A. BARREN, E. H. BENJAMIN, C. A. BEVER, R. P. BOWLER, W. H. BLAUVELT, A. I. BRAID, J. H. BYRNE, C. S. CAREY, H. O. CHUTE, THOMAS H. CLAGETT, W. W. COE, GEORGE L. COL-LORD, E. I. COOK, C. R. CORNING, J. S. COX, JR., W. N. CRAFTS, S. W. CROXTON, A. T. CROXTON, H. G. DALTON, A. E. DANFORTH, E. V. D'INVILLIERS, L. E. DUNHAM, F. A. ENMERTON, W. E. C. EUSTIS, A. H. EUSTIS, A. I. FINDLEY, E. L. FORD, P. A. FRUEHAUF, C. H. FULTON, H. F. FULLTON, JAMES GAYLEY, S. L. GOODALE, H. C. HALE, A. V. HANSELL, J. W. HAMILTON, H. T. HARRISON, ELWOOD HAYNES, H. H. HINDSHAW, H. D. HIBBARD, G. S. HUMPHREY, R. W. HUNT, J. D. IRELAND, L. E. IVES, ZAY JEFFRIES, F. G. JEWITT, J. E. JOHNSON, JR., NASON JOHNSON, WILLIAM KELLEY, J. F. KEMP, CHARLES KIRCHHOFF, WILLIAM KOEHLER, H. M. LaFOLLETTE, FREDERICK LAIST, E. F. LAKE, H. W. LASH, A. R. LEDOUX, I. P. LIHME, J. B. LIVINGSTON, E. J. LONGYEAR, D. A. LYON, W. W. MACON, JAMES W. MALCOLMSON, H. A. MARTING, SAMUEL MATHER, S. McMARSHALL, PAUL O. MENKE, H. G. MERRY, P. N. MOORE, C. B. MURRAY, E. W. PARKER, H. H. PARROCK, WILLIAM PECANKA, J. S. PELTON, G. W. PFEIFFER, S. H. PITKIN, FRANKLIN PLAYTER, J. D. PRICE, JOHN M. PRICE, CHARLES F. RAND, WILLIAM RATTLE, JR., J. B. READ, J. C. REITZ, F. B. RICH, G. A. REINHARDT, C. S. ROBINSON, E. F. ROEBER, W. N. SAWYER, F. SCHNIEWIND, W. SCHU-MACHER, R. B. SHERIDAN, J. M. SHERRERD, A. W. SMITH, E. GYBSON SPILLSBURY, H. S. STEBBINS, S. C. STILLWAGON, H. H. STOEK, BRADLEY STOUGHTON, JOSEPH STRUTHERS, KNON TAYLOR, OSCAR TEXTOR, R. B. TEXTOR, J. E. THROPP, JR., F. H. TREAT, B. W. VALLAT, F. R. VAN HORN, KARL E. VOLK, FRED F. WALTHER, C. M. WELD, S. T. WELLMAN, EDMUND WENDEL, C. L. WOOD, WALTER WOOD, H. B. B. YERGASON, CARL ZAPFFE.

## Market Reports

### LOCAL METAL PRICES

San Francisco November 7.

Antimony.....	11-11½c	Quicksilver (flask).....	41.50
Electrolytic Copper.....	18-18½c	Tin.....	62-63½c
Pig Lead.....	5.00-5.95c	Spelter.....	8½-8½c
Zinc dust, 1400 lb. casks, per 100 lb., small lots \$9.50-9.75; large \$7.50-8.00			

### METAL PRICES

(By wire from New York.)

NEW YORK, November 6.—Copper is quiet, since buyers are still holding off. Lead is also quiet and weaker, since there now is some pressure to sell. Spelter remains quiet but steady. Average daily prices for the past week, in cents per pound, based on wholesale transactions, standard brands, are given below.

Date.	Electrolytic Copper.	Lead.	Spelter.	Silver, per oz.
Oct. 31.....	17.12	4.98	7.20	62½
Nov. 1.....	17.10	4.98	7.20	62½
" 2.....	17.10	4.89	7.20	62½
" 3.....	Sunday.	No market.		
" 4.....	17.10	4.85	7.20	62½
" 5.....	Holiday.	No market.		
" 6.....	17.12	4.73	7.20	62½

## Company Reports

### SIMMER & JACK PROPRIETARY, LTD.

This company was reconstructed in 1896 and has an authorized capital of £3,000,000, all issued and fully paid. The following table shows the results for the year ended June 30, 1912:

Development done, feet .....	4,566
Ore reserves, tons, at \$6.20 per ton .....	2,680,000
Ore mined during year, tons .....	922,624
Percentage of waste sorted out .....	7.15
Average number of stamps working .....	320
Average number of tube-mills .....	7
Ore crushed, tons .....	863,500
Stamp-duty, per day, tons .....	7.45
Costs: Mining, per ton .....	\$1.70
Development, per ton .....	0.07
Ore transport and crushing, per ton .....	0.09
Milling, per ton .....	0.22
Tube-mills, per ton .....	0.14
Sand treatment, per ton .....	0.23
Slime treatment, per ton .....	0.11
General charges, per ton .....	0.24
Renewals, etc., per ton .....	0.02
Total cost per ton .....	\$2.84

Total cost .....	\$2,555,000
Working profit .....	2,646,000
Dividends .....	2,240,000

The report states that sand-filling of worked-out areas has been so successfully carried out on a comparatively small scale during the past two years it has been decided to extend the system, and new plant for this purpose is in course of erection. A magnetic separator was installed in the tube-mill circuit, the slime plant enlarged, and sundry improvements made to plant.

### GRANBY CONSOLIDATED MINING, SMELTING & POWER CO., LTD.

The annual report of this important company for the year ended June 30, 1912, shows the following details:

On account of a strike, working time was only 237 days.	
Ore smelted from Granby mines, tons .....	721,719
Ore smelted from other mines, tons .....	17,800
Average recovery per ton:	
Copper, pounds .....	18.39
Silver, ounces .....	0.29
Gold, ounces .....	0.043
Metal production:	
Copper, pounds .....	13,231,121
Silver, ounces .....	225,305
Gold, ounces .....	33,932
Cost per ton, excluding marketing blister copper .....	\$2.90
Revenue .....	\$2,874,760
Expenditure .....	2,291,381
Net profit .....	583,379
Depreciation, etc. ....	600,562
Assets:	
Fuel and supplies .....	164,191
Cash and copper .....	791,789
Liabilities:	
Dividends held .....	1,603
Accounts payable .....	19,539
Surplus .....	2,516,121

At the annual meeting of stockholders the number of directors was reduced from 15 to 13, and by-laws were amended to the effect that officers' salaries should be fixed by the board instead of by shareholders, as formerly. The report states that, since resuming operations at the smelter on December 21, 1911, general results have been satisfactory except for the excessive cost of coke. The plant is in excellent condition, and there is no reason why as good

or better results may not be expected in the future. A good deal of prospecting has been done in the country around Grand Forks and Phoenix for a radius of 200 miles, and several claims have merit, but will be considered later on. Already \$200,000 has been spent at the Hidden Creek property, and it is estimated that about \$1,600,000 more will have to be spent on development and equipment. There is 5,000,000 tons of ore actually opened, averaging 2.2% copper, against the Phoenix average of 1.25%. The Bonanza group of claims, about one mile from the Hidden Creek smelter site, are under option by the Granby company, and a large deposit developed, assaying from 3 to 11% copper. If development continues favorable, the property will be taken over, the option price being low.

### EL ORO MINING & RAILWAY CO., LTD.

Compared with the year ended June 30, 1911, the last annual report of this company shows a decrease of \$171,000 in profit, due to the smaller output for the six months ended June 30, 1912. It was decided, at the beginning of the current year, on account of the state of the San Rafael vein in the upper portion of the mine, to reduce the annual profit to about \$730,000. Under this policy the quantity mined was limited to 20,000 tons of ore per month, in addition to the treatment of 15,000 tons of accumulated tailing; and since the end of March 35,000 tons has been handled. In A. F. Main's report it is stated that on the San Rafael vein very little ore may be expected from the 286-ft. level to the andesite capping, between the north shaft and boundary. The 386 and 486-ft. levels in this section will yield a small tonnage of low but workable grade ore, while development in the northern part of the 550-ft. level has added to the reserves of \$7 ore. About 20,000 tons of ore has been opened in the southern orebody between the incline and San Rafael shafts. On the 1150-ft. level north of the Somera shaft, the Branch vein is 4 ft. wide, averaging \$25 per ton, and there will be a stoping length of 700 ft. of \$20 ore on this orebody. At the 1300-ft. level the San Rafael vein shows a width of 30 to 50 ft. of poor ore. The Branch vein, on the intermediate drift, between the 1150 and 1300-ft. levels, shows 250 ft. of \$25 ore, 4 ft. wide. On the 1450-ft. level the cross-cut from the Somera shaft passed through a lode 12 ft. wide, but of little account, at 115 ft. west; and at 190 ft. from the shaft, cut another poor lode, 23 ft. wide. On the 1600-ft. level the cross-cut, at 320 ft., cut a lode 18 ft. wide, but valueless. Development in the Somera claim has added considerably to the reserves above the Zero level. The shaft on the Carmen property is to be used to prospect the southern portion of El Oro claim, which is at present unexplored. On the 1600-ft. level a 500-gal. capacity electric pump has been installed, and another one is to be placed on the same level. Ore reserves total 301,934 tons averaging \$9.26 per ton. The following table shows the results of the past year's work:

Ore treated, tons .....	302,698
Tailing treated, tons .....	84,459
Average stamp-duty per day, tons .....	8.88
Extraction:	
Gold, per cent .....	87.51
Silver, per cent .....	74.23
Assay value, per cent .....	85.14
Bullion recovered .....	\$2,228,190
Costs:	
Mining, per ton .....	\$1.47
Treatment, per ton .....	1.12
Development, etc. ....	1.10
Total .....	3.69
Total expenditure .....	\$1,430,119
Profit from railway .....	120,220
Total profit .....	910,000
Dividends paid .....	715,000
Carried forward .....	398,000

The report is presented in the usual lucid style customary with many English and few American mining companies.

## Concentrates

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

**TREATMENT** at the Cam & Motor mine, in Rhodesia, will consist of crushing, roasting, fine grinding, and cyaniding about 15,000 tons of ore per month. One of the metallurgical troubles in this country is antimony.

**DIAMONDS** valued at \$27,320,000 were produced by the De Beers company during the year ended June 30, 1912. The stocks of 'blue ground' on the floors at that date totaled 10,416,429 'loads' of about 1800 lb. each. The yield is from 0.23 to 0.41 carat per 'load.'

**DYNAMITE** manufactured by the Cape Explosives Works, owned by De Beers diamond company, of South Africa, amounted to 423,799 cases during the year ended June 30, 1912. This is mainly used at the diamond mines, and the gold mines on the Rand.

**CYANIDE RASH** may be relieved by applying a mixture of 3 oz. of camphor dissolved in one pint of olive oil, by heating. This complaint is mainly external, that is, the condition of the blood has little to do with it, as perfectly healthy men are troubled, and medicine is not necessary. Another treatment is the application of a fairly strong solution of potassium permanganate, which dries up the rash in quick time.

**EXPERIENCE** has shown that, to a large extent, the safety of workmen and the efficiency of mine management depend on the length of term of office of mine officials. No advantage can be gained by frequent changes of the personnel of a mine. At the same time, there have been numerous cases in which mine officials are 'married to the job,' so to speak, and get very careless unless given an occasional shake-up.

**MINE** fires, like most other fires, start in a small way, only excepting those starting from explosions of gas or coal-dust. A large proportion of them, like other fires, are caused by carelessness, particularly in metal mines. In coal mines, and in some sulphide-ore mines, fires may originate from spontaneous combustion in the filled or broken ground; yet even such a cause often may be attributed to improper and preventable conditions, or to a wrong system of mining.

**URANIUM** in the United States excites popular interest on account of its connection with radium, the properties of which appear so marvelous when compared with those of more familiar materials. But very little uranium is mined in this country except as it is incidentally taken out in mining carnotite for vanadium, according to the United States Geological Survey. In 1911 the uranium mined amounted to about 21.2 tons. A few hundred pounds of pitchblende was mined from the German mine, at Central City, Colorado, but this material was not sold, as it was said to have been used in experimental work. The extraction of radium has been attempted in the United States by several persons and firms. Some of these have given up their efforts, but others are still at work, with what success is unknown. The uses of uranium and its compounds are comparatively few. It is employed principally for making yellow glass, for yellow glazes on pottery, and in a less degree as a chemical reagent. Yellow glass made with uranium oxide is known as opalescent. Direct light shining through it gives a yellow color and indirect light a greenish yellow. Some of the firms which have attempted to use uranium in the manufacture of steel have abandoned such experiments, the claim being made that it apparently imparts about the same properties as tungsten and is very much more expensive.

## Recent Publications

**GEOLOGIC ATLAS OF THE UNITED STATES. LLANO-BURNET FOLIO, TEXAS.** By S. Paige. U. S. Geological Survey Folio No. 183. 23 pp., ill., maps. Washington, 1912.

**REPORT ON THE BUILDING AND ORNAMENTAL STONES OF CANADA. Vol. I.** By W. A. Parks. Department of Mines publication. 376 pp., ill., maps, plans, index. Ottawa, 1912.

**THE COKING OF COAL AT LOW TEMPERATURE, WITH A PRELIMINARY STUDY OF THE BY-PRODUCTS.** By S. W. Parr and H. L. Olin. University of Illinois Bulletin 30. 46 pp., ill. Urbana, June 1912.

**THE COAL FIELDS OF KING COUNTY.** By G. W. Evans. Washington State Geol. Survey, Bulletin No. 3. H. Landes, Geologist. 247 pp.; ill., maps, index. Olympia, 1912. This publication contains eight chapters under the following heads: (1) Geology of Coal; (2) General Geology of the King County Coalfields; (3) Detailed Geology of King County Coalfields; (4) Classification of Coal Lands; (5) Coal Mines of King County; (6) Coal-Mining Methods; (7) General Character of King County Coal; and (8) Markets for King County Coal. In the above chapters, every detail has been carefully discussed, while there are numerous maps of the districts and photographs of plants connected with the mines.

**OUTLINE OF THE SMOKE INVESTIGATION.** Bulletin No. 1. Department of Industrial Research, University of Pittsburgh. 16 pp. Pittsburgh, August 1912. The soot question in large, and especially in industrial cities, is one of considerable concern. Besides several million tons of coke and large quantities of natural gas, 16,500,000 tons of coal is used in Pittsburgh annually, with the result that the smoke thus produced is a nuisance. The staff of the University of Pittsburgh in charge of the investigation includes R. C. Benner and 26 engineers, botanists, chemists, physicians, meteorologists, and others, who have two problems to decide, the analytical or diagnostic, and the constructive or remedial. This bulletin contains short discussions on the first problem, and is of considerable interest to all inhabitants of cities.

**PROCEEDINGS OF THE SYDNEY UNIVERSITY ENGINEERING SOCIETY, 1911.** Edited by J. P. V. Madson, R. J. Boyd, F. D. Power, and E. W. McKeown. 163 pp.; ill., diagrams. Sydney, New South Wales, 1912. This publication deals with the proceedings of the 1911-12 session, and contains the following interesting papers and other matter: Presidential address by W. E. Cook, who discussed 'The Biological Purification of Sewage'; 'Metallurgical Treatment at Mt. Morgan, Queensland,' by G. J. Saunders, in which chlorination of the sulphide and smelting of the copper ores was fully explained; 'The Design of Storm-Water Drains,' by J. Vicars; 'Notes on Harbor Engineering,' by H. D. Walsh, a valuable discussion on construction of wharves, sheds, etc., of wood and reinforced concrete; and 'The Artificial Lighting of Buildings,' by H. G. Carter and J. B. Campbell.

**PORTLAND CEMENT RESOURCES OF ILLINOIS.** By A. V. Bleininger, S. F. Lines, and F. E. Layman. State Geological Survey Bulletin No. 17. 115 pp.; ill., index. Urbana, Illinois, 1912. The production of portland cement in Illinois in 1910 was 4,459,450 bbl., out of the total in the United States of 76,549,951 bbl., averaging 89c. per barrel. This report is of value and interest, in that it contains a thorough description of the raw materials for, and the processes of, manufacture of cement. In a not too technical manner the former is described, while the latter is of interest in the details given of mining or quarrying limestone and clay; crushing by Gates or Blake breakers; drying in rotary driers; intermediate grinding in ball or other mills; fine-grinding in Griffin or tube-mills; and calcining in rotary kilns, the clinker being ground in a variety of mills. A short chapter is given on testing cement. Chapter IV deals with the stratigraphy of Illinois with reference to portland cement materials.

## EDITORIAL

ATTEMPTS by China to borrow \$50,000,000 from London bankers have furnished 'copy' for journals the world over for months; the \$50,000,000 bond issue for state highways voted on in New York state on Tuesday of last week was given only a couple of lines at the bottom of the column in financial and technical journals.

RESULTS at Stratton's Independence, as noted in our news columns, are peculiarly gratifying. Not only are the low-grade ores being treated at a surprisingly low cost, but the figures realized, \$1.503 per ton, are even slightly better than the estimate of \$1.52 made by Mr. Philip Argall before the work was undertaken. Such an outcome is of direct benefit to the members of the profession everywhere, since they give renewed confidence in the ability of an engineer to forecast results.

PROTEST against increase of the rate of pay of shovelers in Arizona mines to \$4 per shift is another evidence of the slight regard in which his important activity is held. Designated as a 'mucker,' 'mullocker,' or 'boger-out,' epithets which contain little of compliment, his work has an important influence on the total cost of operation, and its many unpleasant features deserve a corresponding wage. The fundamental criterion is to pay such a wage as will operate to get the most work done at the least total cost per ton.

FUN of good wholesome sort is to be generously mingled with the serious sessions of the American Mining Congress at Spokane, November 25 to 29, inclusive. In particular an old-time mining camp, 'Taylor Gulch,' is to be reproduced two nights of the week in a large building available for that purpose. Following the meeting proper there will be a two-day excursion to the Coeur d'Alene, affording opportunity to visit the Bunker Hill & Sullivan, Morning, and other of the great mines of that district. In the program prominence is being given to Alaskan problems and a large delegation from the North is anticipated. Land laws, miners' compensation, taxation of mines, and other topics of direct and live interest will be discussed, and every mining man who can do so should arrange to attend and take part.

CABINET-MAKERS are busy volunteering advice to Mr. Wilson. One of the most sensible suggestions is that an engineer should be chosen as head of one of the departments, preferably that of Interior. In view of the large amount of engineering work that the Government always has under way, the President should have among his closest advisers one who is thoroughly familiar with engineering procedure and practice. If such a man be placed at the head of the Department of Interior, it would be particularly appropriate to have a mining engineer chosen, since the greater problems of the West are intimately connected with mining. In the past there has been too much of a disposition to leave everything to lawyers, and we are firmly persuaded that results will be much more satisfactory if men of many lines of training be made responsible for administration of our common affairs.

**H**UNT for new avenues for consumption of copper sometimes verges on the absurd. Our New York correspondent refers to the computations regarding the cartridge cases required in the war now in progress in the Balkans. It is, of course, unkind to suggest that empty cartridge cases may be picked up and sold as scrap, especially in a country where labor is cheap and abundant. The beneficial effect of the presence of copper in steel rails has also been widely commented upon as a possible demand for copper. Many iron ores contain small amounts of copper, the ore from Ta-yeh, China, contains 0.05 to 0.25 per cent copper, while ores from Cornwall and other places contain perceptible amounts of that metal. Even if the use of copper-bearing steel should become general in railroad practice, it is only reasonable to suppose that a part of the copper necessary will be secured by the utilization of ores containing it, and in any case the amount necessary would not exceed a small fraction of one per cent of the present annual production.

**C**OMPARISON of the crushing effected by stamps and grinding pans in the article on Huntington mills at Kalgoorlie is of much interest. That the stamp-mill does its best work upon rather hard brittle ores, while machines which depend upon pressure and trituration for their crushing effect make a correspondingly good showing upon softer oxidized ores ought to be generally known, but, like most truths, it bears repetition. There is often too much of a tendency, especially among those of limited experience, to adhere to a single type of machine, in the mistaken belief that better results will be obtained in this way than by attempting to learn the 'kinks' of an unfamiliar type. Reasoning of this sort appeals more strongly to the shift-boss than to the manager, and while it has a certain amount of force in some cases, it should not be allowed too much emphasis. When machinery is carefully chosen, in view of the work it is called upon to perform, the best results will follow in the end. The stubbornest workman can eventually be trained, or at any rate discharged, but a tube-mill can never be altered into a coarse-crushing device, nor a gyratory crusher adapted for all-sliming.

**B**ORROWING money is a difficult task, as many individuals have found. It is now reported that the attempt to secure funds for the new Chinese republic outside the international group of bankers who have the support of their respective governments, has proved a failure and negotiations with the six-power group are to be resumed. Not improbably they will be quickly carried to a conclusion, since China has shown sufficient spirit so that impossible terms will not be asked, while the strength of the group of bankers is so evident that further attempts to secure large sums without their coöperation will be discouraged. It is impossible to unravel the threads of diplomatic intercourse, but it has all along been evident that a string of political privilege was at first tied around the foreign banknotes. China properly resented this, but, on the other hand, she is not in a position to stand upon her dignity in regard to foreign supervision of the accounts of the salt gabelle which was to form part of the security for the new loan. It is even doubtful if it is wise for her to object to this; the Imperial Maritime Customs, which has for years been under able foreign supervision, has been the greatest and most effective educational institution in the nation, and the present excellent post-office, telegraph, and telephone systems which China enjoys are the direct outgrowth of its influence and activity. Chinese autonomy did not suffer in this case by utilizing the skill and experience of the foreigner, and it is not improbable that history would repeat itself were a similar course of action now followed.

### Taking Care of the Workman

Care for the welfare of employees is an essential phase of the business management of large enterprises. Quite aside from any humanitarian aspects of the matter, it is good business to see that workmen are well fed, well housed, well clothed, and free from causes of worry and discontent, since under these conditions the laborer is able to do more work of better quality. The careful study given this matter during the last two decades is one of the most important features of modern social progress. The relations of employer and employee have exhibited a pendulum-like swing since medieval times. In feudal times the overlord looked after every phase of the welfare of his retainer, in theory, but in practice so neglected his responsibilities and abused his powers that industrial revolution followed and the relations of the laborer and the *entrepreneur* were sharply defined by being put upon the simple basis of a money return for labor performed. Now that the rights of the individual are clearly established and we are making encouraging progress in the control of large aggregations of capital, with their collateral power for good or ill, it is becoming evident to all that so simple a relation between employer and employee does not completely fulfill the condition of securing the maximum of desirable result from the minimum of expenditure of energy, conveniently represented by money. The *entrepreneur* can, in many ways, perform much greater service for the laborer with ten cents of his wage, than the laborer can do for himself, just as a street-car company can operate its lines at a profit from the nickels collected from the passengers, whereas the individual passengers could not individually buy the service even for a many times greater sum. The profits made by insurance companies have served as an educational agency, and their significance cannot be gainsaid. As a result, progress toward providing for insurance against sickness and accidents, and even the pensioning of superannuated employees in those cases where the number employed is great enough to make it practicable and desirable to undertake such service has been rapid. Pensioning of state and Federal employees under certain circumstances has been practised for some time, while private corporations often make provision for insuring employees against loss of earning power through sickness or accident. The most recent application of this method of increasing the welfare of the employee is its adoption by the affiliated companies which make up the Bell telephone system. From the funds of the corporate enterprise, which employs 175,000 men, the sum of \$10,000,000 has been set aside to provide the income necessary to pay sickness, accident, and death benefits, and to provide pensions for all employees over the age of 60 years, who have been over 20 years in the employ of the company. This fund is to be administered by a committee of five employees appointed by the Bell company, and, if well administered, as no doubt it will be, the benefit to the employees of the company will be many times greater than if the same amount of money were expended in increasing the individual wage. Provision against want in old age has not the attractive clink of a little extra money in the pay envelope, and education of the employee as well as of employer is necessary to secure the full realization of the usefulness and importance of progress in this regard.

Equally useful service for the employee can be secured in other ways, and it is interesting to notice that the Great Cobar, Limited, in the enterprises under its direction in New South Wales has undertaken to provide employees with food at a reasonable rate and maintains for that purpose a bakery and butcher shop. It is obviously an exhibition of better business management for the company to expend small amounts in providing its men with bread

and meat of good quality at the minimum price than to increase wages and have the increase go to swell the profits of the local merchant, who, though his enterprise is legitimate enough, does not directly benefit either employer or employee. A similar system has been employed for many years by several of the principal mining companies of Japan. Company stores there sell rice, the chief article of diet, to the workman at a uniform rate throughout the year; the rate being slightly less than the average price for the year, and the slight loss thus accruing to the company is charged to the wage account. The workman, on the other hand, is protected from sudden variations in the cost of food; in other words, the industry protects the individual from fluctuations which affect his welfare, but over which he has no control. A similar practice is followed by some American companies, and the Alaska Treadwell, for example, maintains a company store in order to keep the price of the necessities of life in that district at a level which will prevent the exploitation of workmen by local merchants, and has recently put in force a system providing for inspection to secure the safety of employees and the payment of compensation for accidents. Theorists may object that this is paternalism, but the average workman is a pragmatic philosopher, and when he realizes the best results for himself can be secured by methods such as these, is not likely to be frightened by a name.

### Patents and Litigation

Announcement was made last week by the United States Circuit Court of Appeals for the Third District, of its decision in the case of *The Moore Filter Company v. Tonopah Belmont Development Company*, heard on appeal from the Circuit Court of the United States for the District of New Jersey. The questions at issue involved the validity of the Moore patents and their infringement by the Butters Patent Vacuum Filter Company, which concern, in accordance with its agreements with users of the Butters filter, has been defending the suit. The result of protracted and expensive litigation is a sweeping decision sustaining the Moore patents, and the cause is remitted to the lower court with instructions to enter a decree adjudging infringement and for such action in the way of injunction and accounting as it shall deem fitting. Faulty wording of a telegram led us to announce the decision last week as from the Supreme Court, though the difference is not, for present purposes, material. The full text of the decree of the court will be printed next week, and we shall reserve until that time a specific discussion of the matter. The occasion seems appropriate, however, for taking up one defect of present practice as regards patented articles and its effects on machinery users.

In considering the litigation over filters, roasting furnaces, concentrating tables, or any one of a dozen other devices used in mining or metallurgy, the engineer is impressed most of all by the enormous amount of time, energy, and money required under existing conditions to establish and defend a patent to even the most useful invention. To men employed in mining and treating ores, this expenditure appears to be nothing but economic waste. Whatever may be the individual profits or losses, it is difficult to see any adequate return to the industry that the inventions were designed to serve; and in the long run the cost of all such litigation must be borne by the mines. In one case a company has spent nearly \$150,000 in defending patents on one of the most useful machines given to the miners in recent years, and even yet is far from having a clear field. Probably much larger sums have been spent by others, and the total amount involved in court expenses, attorneys' fees, and preparation of expert testimony forms a staggering

total. It is only the work of the technical expert in preparing for a case and in giving testimony, that is likely to be of any economic service to industry, and even then the money and time could be expended to greater advantage in impartial research. The buyer of machinery is wholly at sea. He no sooner purchases his mill and begins operations than he is served with an injunction or a notice that royalties will be claimed by a rival patentee. He is constantly exposed to the danger of paying double for the use of a piece of apparatus. It is impracticable for each buyer to personally investigate the rights of rival claimants and he could in any event come to no valid conclusion, since the inventor himself does not know his own rights until they have been adjudicated by the courts. Often patented articles are sold under guarantees of protection by the selling company, but the latter is usually a limited liability concern and protection adequate in a specific case breaks down before a general onslaught. Insurance companies in San Francisco, for example, had always afforded adequate protection against fire losses, but the conflagration of 1906 bankrupted many and left policy-holders unprotected. It would take much less to sweep away the protection given many buyers and users of patented articles.

There is a general and mistaken impression as to the protection afforded by a patent. Cynical observers say that a United States patent merely affords the holder the right to go into court, and there is entirely too much of truth in this assertion. In patent cases too many matters are now left to the courts, and in these, as other cases, complexity of procedure leads to practical denial of justice. In a specific case now being litigated where the validity of a particular patent had already been adjudged, suit for infringement with application for injunction, was brought before an able and impartial judge. He asked that the application for injunction be withdrawn because, as he said, the case was so simple that the whole matter might well be decided in sixty days. In fact the case is still before the court, after two years, despite the best efforts of the prosecution to secure trial. In the meantime the presumable infringers have manufactured and sold the competing device. In many cases the infringer is not so much mistaken as dishonest, and there is a lucrative business for patent experts and attorneys who care for such practice, in devising means whereby a client may 'get around a patent.' Owing to the law's delay an infringer of no financial standing can manufacture and sell for years, making enough to keep up pretense of a fight, and eventually leaving his victims to account later with the successful litigant.

There is abundant room under existing conditions for honest differences of opinion, as exemplified by the Moore-Butters and other famous cases, and a reasonable burden of expense in such connection is probably unavoidable, but between the defects of the patent law, the inadequacy of patent examinations, and the growing tangle of court procedure, there is a far heavier burden of unjustifiable expense due to dishonesty and fraud. We are not concerned here with assessment of blame so much as recital of facts, nor are we attempting to discuss all the defects or any of the remedies. We would, however, insist that the condition is serious, and we would emphasize the fact that every user of a patented article has a direct financial interest in seeing that a simpler method be devised for securing even justice between rival patentees. The mining and metallurgical industries in particular need the best efforts of the best men to improve practice, if the output of metals is to keep pace with the world's increasing demand, and neither industry is so rich as to permit it to submit tamely to continued and unnecessary waste of time, energy, and capital.

# Huntington Mill Practice at Kalgoorlie

By M. W. VON BERNEWITZ

It is doubtful whether a better insight into the working of the Huntington mill can anywhere be obtained than on the Kalgoorlie field, where at the present time there are ten mills at work. In the outside districts there are ten more, and at Ora Banda a large plant with four mills has just started. While this article deals chiefly with Huntington mill practice, an attempt has been made to discuss the treatment of low-grade oxidized ores at the small mines and a comparison is made with stamps on similar ores around Kalgoorlie, more especially at the north end, about three miles from the 'Golden Mile.'

To give an idea of the ores handled at these plants, a quotation from Larcombe's 'Geology of Kalgoorlie' will suffice: "In ores from the zone of oxidation much iron oxide is present, varying from ochreous varieties to hard compact ironstone, with which is associated much ferruginous clay or kaolin, resulting from the decomposition of the country rock. Quartz is also present, representing the silica remaining after the breaking up of the small veins characteristic of the deeper zones." The ore deposits of the north end are somewhat different from those at the south end of the field, however, but no doubt the oxidized product is similar, with the exception of containing less quartz. The veins at the north end are generally small, and in consequence much clay and ironstone can be expected in the oxidized product. An analysis of this ore shows:

	%		%
SiO <sub>2</sub> .....	50 to 65	Al <sub>2</sub> O <sub>3</sub> .....	10
CaCO <sub>3</sub> .....	7	Fe <sub>2</sub> O <sub>3</sub> .....	12
MgCO <sub>3</sub> .....	5		

In these small mines the workings are by open-cut, or from depths of 150 ft. The Golden Dream, for example, in its last half yearly report, gives the width and average assays of three veins; 30 ft. of \$1.80 ore, 15 ft. of \$2.16 ore, and 30 ft. of \$2.60 ore, 7000 tons worth \$2.60 per ton being ready to mine. At several of these small mines the ore is hoisted by means of Taylor friction hoists. This machine consists of a single drum driven by a grooved or friction pinion, in turn driven by a motor. The man on the surface, by means of a long lever of 1-in. pipe, controls the hoisting of ore, or lowering the bucket or cage, as the case may be; therefore the expense of a hoisting engineer is eliminated. The ore is trammed to the mill. In some cases a crusher is used, while at others the ore is broken by hand to the size for milling.

For driving the machinery, either gas-engines or electric motors are used, costing 2 cents per brake-horse-power-hour for the former, and up to 5c. per unit for electricity. The Huntington mills are fed by Nelson (improved Challenge) feeders, belt or eccentric driven from mill shafting. The pulp flows over one long, or several short copper plates, and then to either spitzkasten or collecting vats, the slime going to dams. The clean sand is then shoveled into vats for a seven-day treatment with cyanide solution. The plants are fairly well designed, and certainly costs show much technical skill. Such mines cannot afford to have idle directors, and large staffs. Everybody works hard, and the owners are able to doctor their engines and motors, repair mills, cyanide the sand, clean up, and generally get satisfactory results. Every man I met on several rounds of inspection was always busy, but

ever ready to impart any data needed, if available. At such mines the owners do not deem it necessary to go into exact refinements of tonnage, grading analyses, and costs. Those cited here are as given me, though many lack full details. The earliest Huntington mill plants on the Kalgoorlie field were erected on the Associated, Oroya, and Hannan's Proprietary mines, which had three mills each. They stopped work in the order given, the latter working till last year, having a run of about 14 years, mostly on customs ore. When I came to Kalgoorlie, toward the end of 1899, the Oroya plant was crushing 100 tons daily of oxidized ore from an open-cut. This only averaged \$6 per ton, and the company paid a dividend on such low-grade ore, at the time of high returns from the large mines.

The Huntington mill, generally of the 5-ft. size, is an excellent machine for crushing and amalgamating all soft ores, similar to those described, or those of a fairly quartzose character; and probably no machine will beat it at this work. Crushing is done by pressure largely, and impact slightly; say pressure-impact. A certain amount of crushing is also done by grinding, as the rollers must exert some rubbing action while pressing against the die-ring, revolving at the same time. On this class of ore, fully 50% is slimed, yet the machine does not make an excessive quantity of slime, throwing out the pulp as soon as it is the required size to pass the screen, which always tends to efficient duty. It has been found on the field that, on the average, the slime assays lower than the sand, just the reverse of stamp-mills on the same ore.

The erection of a Huntington mill is very simple. A good concrete foundation is necessary, upon which the 12 by 12-in. wood frame, supplied with all mills, is bolted. The mill bottom is then bolted to the frame, and then the false bottom is fitted in and cemented up. The die-ring is lowered in place and wedged up evenly all around, wood wedges being procured locally from one of the timber mills. The pinion-shaft, vertical spindle, and gear are next fitted and lined up. The housing is bolted on to the bottom of the mill, not forgetting the jointing. The disc driver, which carries the rollers and scrapers, is keyed to the vertical spindle. The roller shells are wedged on, and the spindles carrying these are fitted into the yokes, which hang from the disc driver. The rollers should be 1 in. from the bottom of the mill, and the top of these should be level with the die-ring. The scrapers are set about 1/4 in. from the pan bottom. Mills are made with three or five openings for discharge of pulp, and are fitted with punched screens.

The table below shows the dimensions of Huntington mills as supplied by Fraser & Chalmers.

The mill is a good amalgamator, and on this class of ore, the gold being rather fine, amalgamation varies from 25 to 60%. The mercury fed into the mill gets well mixed with the pulp by the action of the rollers and scrapers, causing a general violent circulation. A short lip plate is generally used. Some plants have a single copper plate about 12 by 5 ft., while others have two or three short plates covering that length, with a well between each. The owners argue better results are obtained by the latter system. The former also appear to be satisfactory, so each works on experience gained. The Huntington need not be fed with as

DETAILS OF HUNTINGTON MILL CONSTRUCTION

Diam. of mill.	Width of frame.	Length of frame.	Height of frame.	Total height of mill.	Height from floor to discharge.	R.p.m.	Hp.	Weight.
3 1/2 ft. ....	49 1/2 in.	79 in.	27 in.	56 3/4 in.	35 1/2 in.	90	4	8,000 lb.
5 ft. ....	66 in.	120 in.	34 in.	68 in.	40 in.	70	6	15,000 lb.
6 ft. ....	78 in.	132 in.	37 in.	77 1/2 in.	47 3/4 in.	55	8	20,000 lb.

much mercury as a battery, as it is being continually brought into contact with the pulp in circulation.

In a 5-ft. mill the pinion or pulley shaft revolves at 140 r.p.m., and the vertical spindle 70. The step-bearing of the latter requires plenty of good oil, and the gear should be well greased, thus prolonging the life for years. The bushing of the bearing, and the steel toe and button do not require renewing very often. The rollers should

HUNTINGTON MILL AT LAKE VIEW SOUTH.

be regularly oiled. The Nelson feeders are driven by an eccentric or belt from the mill pulley shaft. The average size of feed is 2 in. The ore as fed in is immediately caught by the scrapers which throw it in front of the rollers, which in turn crush it against the die-ring. The four scrapers are placed staggered in the disc driver, and it is important that these be kept in good order, renewing the shoe as soon as worn to any extent, especially the one nearest the die-ring. If the scrapers are not attended to they will not throw up the ore to be crushed. By the sound of the mill, the attendant can judge how it is crushing. When fed just right, a rumble is heard; but when overfed, there is a swishing sound, and ore is to be seen scattered over the bottom of the mill toward the centre. This is bad work, as the rollers drag the ore about, throw out mercury, and the capacity of the mill falls off greatly.

The die-ring should be of uniform steel, else there will be soft patches in it which cause uneven wear, so much so that they have to be replaced at times. Some of the millmen prefer a small 'hump' to form, arguing that the rollers thus swing about more, giving more impact action, but this scarcely seems correct. The makers supply a grinding tool for turning up die-rings. This consists of a spindle, fitted to a yoke similar to the roller, to which is fitted a segment of a circle the same radius as the die-ring, and about 24 in. long, 6 in. wide, and 1½ in. thick. To this is bolted a shoe, which may be renewed when worn. The grinder is put in the place of one of the rollers, and presses hard upon the die-ring, wearing off the uneven spots, this being done when the mill is crushing. Generally, the apparatus is not used here. It

must be a great brake on the mill, and add considerably to the power used, although only in for an hour or so. The millmen apparently consider that when a die-ring wears badly, truing up is only a temporary job, and the uneven wear will occur again, so it is best to renew the ring.

Punched screens of 250 holes, equal to about a 30-mesh wire screen are used in all cases, being the best to stand the heavy splash of the mill. To prevent sand being splashed up into the hub of the roller head, and getting down into the friction rings, all mills here have a piece of 5-in. iron pipe shrunk on, thus preventing the pulp from splashing up. From the tables given it will be seen

ORA BANDA MILL WHILE UNDER CONSTRUCTION.

that the 5-ft. mill crushes from 30 to 80 tons daily, and tests by the Associated Northern showed 120 tons. The former tonnage is on quartz and the second on ordinary oxidized ore, while the last is on a soft kaolin with small ironstone seams in it. The table below gives details of the principal Huntington mill plants.

At most of these plants no proper record is kept of costs, so the table is lacking in details. Some definite costs are promised in a few months from the new plant at the North Boulder, and Gimlet South Extended.

CROSS-SECTION OF HUNTINGTON MILL.

The latest Huntington mill plant to be erected in Kalgoorlie is on the North Boulder property. This is a well designed plant, and has been well built. It consists of a

OPERATION OF HUNTINGTON MILLS, KALGOORLIE.

Name.	No. of mills.	Size, ft.	Speed, r.p.m.	Hp.	Drive.	Hp. of engines.	Daily capacity, each mill, tons.

Lake View South...	..	8	..	..	..

Probably the most interesting and up-to-date plant using Huntington mills, and one which must show record costs for complete treatment, is being erected on the Gimlet South Extended at Ora Banda, 40 miles from Kalgoorlie, by the Associated Northern Co. A description may be of value, and a progress photo of the plant is shown. I had supposed this to be one of largest installations of Huntington mills for primary crushing; but there is a plant of six mills at work at the Zuiho mine in Formosa, crushing 100 tons daily of an ore consisting of slate and limestone. The Associated Northern has developed 160,000 tons of oxidized ore assaying \$5.25 per ton, and was bought for \$110,000. To check the sampling a Huntington mill was erected, and several lots of ore crushed, confirmed this. The mill dealt with 5 tons per hour, or 120 tons daily. The ore is kaolin with intermixed seams of

ironstone which carry the gold. The 350-ton plant, now in full operation, consists of: One jaw-crusher driven by a Tangye gas-engine; 14-in. belt conveyor to mill storage bins, Nelson feeders; four 5-ft. Huntington mills with 30-mesh wire screens; inside amalgamation but no plates; pulp flows down a cement launder to a large two-plunger pump which elevates to spitzlutte; underflow to two 5-ft. grinding pans, pan overflow and that from the spitzlutte to the thickening-tanks; slime to four ordinary style agitators, then to three new type Ridgway machines for filtration of gold-bearing solution, these to deal with 120 tons each daily; residue to be pumped to dam. Two other Tangye gas-engines drive the main shafting. The water used is salt, and costs 87c. per 1000 gallons. It is expected that the complete treatment of this ore will cost \$1.50 per ton. Details of the mill's performance will be given later.

There are a number of stamp-mills at other mines crushing oxidized and customs ore. Of these, the mills on the Hannan's Reward and Hidden Secret are of some note, in that they are fairly well designed. With reference to one of the others, it may be said that five 1000-lb. stamps only crushed 28 tons daily of ore from the Lake View South, as against 50 to 70 tons by the Huntington mill. A few details of these two mills are given below.

As these mills are on customs work at times, costs could not be procured. The Hannan's Reward gets about 50 tons of sand out of 100 tons of ore crushed. The Hidden Secret had a No. 4 Krupp ball-mill working for a time, with a daily capacity of 80 tons through a 25-mesh screen, which compares well with the 100 tons daily crushed by the No. 5 mill at the Chaffers. The wear in the Hidden Secret mill was not very heavy, but for some reason a good extraction could not be secured from the sand. Nine years ago the Eclipse mine, now belonging to the Oroya Links, had twenty 900-lb. stamps crushing the usual class of oxidized ore. These averaged 9 tons daily each, but made a good deal of slime.

In the treatment of the oxidized ore the Associated Northern mill at Kalgoorlie first weighs the ore and takes moisture samples. The ore then passes a No. 5 Gates crusher into bins by distributing belt. Shaking feeders feed the No. 5 Krupp mills, which have a 9-mesh screen, the crushed ore dropping upon a 14-in. belt. Under the mill it is automatically sampled continuously. The belt elevates the ore to a small mixing pan, where it is mixed with 0.04% KCN solution, and then the pulp flows into three 5-ft. pans, the overflow going directly to agitators. It is agitated for 8 hours, pumped into presses, and washed as usual, the residue being trammed away. The total cost of this complete treatment is \$2.25 per ton, being somewhat high on account of the variable tonnages dealt with, common to all custom mills. Manufacturers and textbooks on Huntington mill practice cite the following points in their favor, which seem to be pretty well borne out in practice, though perhaps I have failed to prove them.

Reduced first cost, say two-thirds that of stamps; saving in power, or one-third per ton crushed; wear and tear and cost of renewal less; less flouring of mercury; less freight; erection, one-tenth that of stamps; wearing parts easily duplicated; better discharge, and pulp in a

better condition for concentrating; better amalgamation; less sliming, as pulp is discharged immediately on reaching the proper size.

The whole question of Huntington mills may be summarized by saying that if a soft to moderately hard ore is to be crushed, install one; drive it and other machinery with any good suction gas-engine; treat the sand by ordinary percolation methods, and perhaps the slime with vacuum plant. Cheap and good results should follow. This is an admirable arrangement for any small mine which has to deal for a considerable time with oxidized ore only.

Mining in the Urals

ST. PETERSBURG CORRESPONDENCE

The metal report from Ekaterinburg is favorable for practically all classes of metals produced in the Urals, including the base metals. The copper situation is excellent. Notwithstanding the fact that the production of copper in the district is increasing rapidly, smelters are not in a position to satisfy all the demands made on them, for the present at all events. No reserves of copper exist at the smelters, and the moment it is produced it has to be sent to the buyers. Nevertheless, there does not appear to be any serious increase in prices.

The production at the Kyshtim works is increasing, and it is proposed to extend the copper-smelting operations in the Syssertsk mining district. With the development of the copper-smelting business there is, of course, a big demand for copper ore, which is available only in limited quantities. In the Vertch-Isset mining district the managers, experiencing a difficulty in keeping their Pyshminsk-Klyuchieff copper smelter at work for want of ore, have set aside some land near the smelter for exploitation by free laborers, the condition being that they shall not sink below a certain level for the ore, and that in case the ore should be found deeper than the maximum permitted, the company retains the right of working the deeper lying measures for itself. The free laborers are operating pretty extensively in the Vertch-Isset district in the production of copper ore, which they are delivering to the Pyshminsk-Klyuchieff concern.

The demand for iron ore is also strong, being required to satisfy an insistent demand. Chrome iron ore and pyrite are in good tone. The production of these minerals continually increases and is easily absorbed by a greedy market. There is no stock left either of chrome iron ore or of pyrite. Ground malachite remains at the old prices. The platinum market is somewhat more lively than it has been for some time. There is inquiry for large parcels, but still no big deal has gone through; because generally buyers are not offering satisfactory prices, and sellers simply will not give way; so the price remains at 9 rubles 80 kopeks but stands firm. The free laborers are offering fair quantities, which speculators are buying readily enough in small parcels at prices above the official quotation of 9r. 80k. There is a considerable extension of platinum production by the free laborers for the reasons already given in previous notes on this subject.

Hidden Creek Copper Deposits

By R. G. McCONNELL

\*The claims now controlled by the Granby company were staked about ten years ago, and a considerable amount of surface and underground work was done on them by the Hidden Creek Copper Co. under the direction of M. K. Rodgers. Recently the claims were bonded to the Granby Consolidated Mining, Smelting & Power Co., operating at Phoenix, British Columbia, and a diamond-drill test of the property proved so satisfactory that the bond was taken up and preparations are now being made to work it on an extensive scale. My thanks are due to O. B. Smith, gen-

VICINITY OF OBSERVATORY INLET. GOOSE BAY HAS BEEN RENAMED GRANBY BAY.

eral mines superintendent of the Granby company, and Mr. MacDonald, local manager of the Hidden Creek mine, for permission to examine the workings, for information, and for other courtesies.

SITUATION

The claims are staked on the summit and sides of a hill 920 ft. high, enclosed between two branches of Hidden creek, and situated 8500 ft. north of Goose bay, near its outlet into Observatory inlet. A good wagon-road, planked where necessary, about two miles in length, has been built from the portal of the main adit to a wharf at Anyoux on Goose bay, the shipping port of the mine, and a tramway, partly gravity and partly traction, to the same point, was commenced some years ago, but never completed.

ROCKS

The rocks in the vicinity of the mine consist of dark and dark-gray argillites, with occasional light-colored, coarse-grained feldspathic beds and rarely some limestone. Beds and bands of greenstones, probably largely of pyroclastic origin, occur with the argillites, but are not prominent in the vicinity of the mine. Both argillites and greenstones are always more or less altered, and in places pass into

\*From the annual report of the Canada Department of Mines, 1911.

mica, quartz mica, and chloritic schists. The bedding is coarse, and while a strong cleavage is developed in spots, the bedding planes over most of the area constitute the principal partings. The beds have been compressed into several folds, and in places dip steeply, but are seldom, in the section examined, overturned, and no large faults were observed. The strike, while generally east and west, shows considerable variation in places.

The argillites and associated rocks are exposed over an area about 9 miles wide, where cut by Observatory inlet. They are surrounded by the granite rocks of the Coast range, and are considered to be an undestroyed and deeply sunken portion of the old roof of the Coast Range batholith. The basin they occupy is of great depth, as the sedimentary rocks of the inclusion are exposed from base to summit of mountains over 5000 ft. in height, and they must extend for a considerable depth below the present surface.

The argillites are cut by numerous dikes, one set being older than the mineralization of the region and genetically connected with the enclosing granitic rocks. These vary widely in character and include granitic, dioritic, quartz-porphry, aplitic, and pegmatitic types. In addition to these, a second widely distributed set occurs, the members of which were intruded after the mineralization of the region. These are fine to medium-grained basic dikes, often of a lamprophyric character. Thin sections from the dikes cutting Mammoth bluff showed laths and occasional phenocrysts of feldspar, mostly plagioclase, with abundant brown hornblende in long prisms, and occasional plates of mica. Rounded irregularly bounded quartz grains, possibly of foreign origin, are also present, and large calcite areas probably representing original olivine are of frequent occurrence. A second type obtained from a dike crossing the main adit of the Hidden creek mine between the two orebodies, contained large olivine and augite phenocrysts in a fine-grained hornblende-feldspar base, and is classed as an olivine basalt. A third type, represented by a dike crossing the Redwing, consists mainly of hornblende and plagioclase, and possesses a well marked ophitic structure. The later dikes may be connected with a basaltic flow which caps the hills south of Alice arm. They do not appear to affect in any way the orebodies they cut.

#### WORKINGS

A large amount of surface and underground work has been done on the Hidden Creek mine. The mineralized area is very large and was first outlined roughly by long trenches running in various directions. Subsequently a working adit was started below what is known as Cabin bluff, at an elevation of 530 ft., and has been driven straight into the hill in a northwesterly direction for 950 ft. A drift to the left from the main adit, starting 85 ft. from the face, has been carried in for a distance of 300 ft., and several shorter drifts from points along the main adit serve to explore the ground bordering it.

Besides the main working adit and its branches, a number of shorter adits have been driven at various elevations into the iron-stained slopes of Cabin and Mammoth bluffs. One of these, commencing in a depression at the foot of Cabin bluff, is connected by a raise with the main adit. In addition to the numerous trenches and adits, the mineralized area has been further extensively explored with the diamond-drill by the Granby company, the present owners of the property. A number of long bore-holes, starting from various points along the main adit and from the surface, have been drilled and have yielded valuable information in regard to the general character of the deposit.

#### SIZE AND GENERAL CHARACTER OF THE DEPOSITS

The mineralized area, as shown by the various surface and underground workings, is of great extent, although it has not as yet been fully defined, both ends being still unknown. In shape it forms a right angle. The smaller arm, known as the first orebody, has a northeasterly strike and dips to the northwest. It has been traced from the main adit in a southwesterly direction for over 600 ft.,

the width averaging about 160 ft., or, including a silicious band which borders it on the northwest, of nearly 200 ft. The longer arm holding the second orebody has been traced in a northwesterly direction for a distance of 1500 ft., with an average width of about 400 ft. The deposit has been proved by a bore-hole to a depth of 514 ft. below the main adit or approximately 900 ft. below the surface outcrops on the hill. While only a part of the large area described contains valuable minerals in sufficient quantities to constitute workable ore, the original rocks are everywhere either completely altered into greenish or less commonly brownish micaceous schists or replaced by quartz and iron and copper sulphides. The transition from the dark, slightly altered argillites which constitute the country rocks, to ore is usually fairly abrupt, often occurring in a few inches.

A conspicuous feature of the deposit is the presence of a zone of whitish quartz schists, practically strongly silicified argillites, traceable partly around it. This silicious zone forms the northwestern boundary of the southwestern or smaller arm, crosses the deposit, then bending at right angles continues to the northwest as the northwestern boundary of the larger arm. It was not observed on the southwest border of the larger arm or the southeastern border of the smaller one. The rocks in the silicious zone vary in the amount of silicification undergone. In most places they are nearly pure quartz schists, but occasionally the zone consists of alternating dark and white bands. The width of the zone ranges from 30 to 60 ft. and more. The dip where it skirts the smaller arm and crosses the deposit is to the northwest, but after bending to the northwest the dip, as shown by the bore-holes, changes to the northeast. It thus forms the hanging wall of both arms.

#### MINERALOGY

The metallic minerals present consist mainly of iron pyrite, some of it cupriferous, pyrrhotite, and subordinate quantities of chalcopyrite. A little bornite, evidently secondary, was found at one point. The principal non-metallic constituents are quartz, some calcite, a greenish micaceous schist, probably largely chloritic, some brownish micaceous schists, and occasionally some hornblende.

Pyrite is the most abundant metallic mineral present. It usually occurs in a granular condition, and in places near the surface breaks down into an iron sand. It is always associated with more or less quartz, and large areas consist of pyrite grains separated by a thin silicious matrix. It also occurs in grains and small bunches distributed through the secondary schists. Its distribution through the mineralized area is irregular, some portions containing only a small percentage, while others consist almost entirely of sulphides and quartz. The main adit started some distance down the slope from the mineralized area to gain depth, passes through 380 ft. of argillites, all somewhat altered and containing occasional grains and small bunches of pyrite, then through a pyritic zone 200 ft. wide, becoming very silicious toward the northwest border, then through a greenish schistose zone with some quartz and pyrite 240 ft. wide, beyond which is a second pyritic area which continues to the end of the adit 120 ft. A drift to the left from a point near the end of the adit running about north for 300 ft. shows the continuation of the pyritic area for that distance, the breast being in granular sulphides mostly pyrite, embedded in a silicious matrix. A drift to the left passes through sulphides and quartz for 100 ft., then through greenish chloritic schists only slightly mineralized for 120 ft. The comparatively barren interval separating the two pyritic areas in the adit is not apparent on the surface, some of the ground overlying the lean portion being well mineralized with sulphides.

Pyrrhotite, while much less abundant than pyrite, is common throughout the greater part of the mineralized area. It occurs intermingled with the pyrite and also forming comparatively large masses usually specked with chalcopyrite. Chalcopyrite in grains, small aggregates of grains, and in thin layers usually accompanies the iron sulphides where the replacement is complete or nearly so, and also

occurs in small quantities scattered through portions of the schistose areas. The proportion present, while variable, is always small and in certain areas seems to be absent altogether. The chalcopyrite is associated so intimately with the iron sulphides that there is little doubt that both are the products of the same period of deposition.

Bornite was found at one point, but only as a surface alteration mineral, and it does not occur, so far as known, as a primary mineral of the deposit. Among the non-metallic minerals, quartz is the most prominent. A wide silicious zone crosses and bounds portions of the mineralized area, and the large sulphide areas are all more or less silicious. Calcite occurs occasionally, but is not prominent. Portions of the area included in the mineralized zone on the accompanying map consist of greenish micaceous schists often highly silicious. These carry significant quantities of sulphides in some places and are nearly barren in others.

#### ORES

The iron sulphides in the Hidden Creek mine have a low content in the precious metals. Out of a number of samples assayed in the laboratory of the Mines Department, one showed 0.02 oz. gold to the ton, one 1.65 oz. silver, and the rest only traces. The commercial value of the deposit must, therefore, depend mainly on the copper content. Chalcopyrite usually accompanies the iron sulphides, but in variable amounts. Some areas are nearly barren, while others contain sufficient quantities to constitute a low-grade copper ore; that is, ore carrying up to 3% copper, and over limited areas an even higher percentage.

The most important body of workable ore so far outlined in the boring operations of the company occurs south-east of the silicious zone previously described as bordering the shorter arm of the deposit on the northwest and continuing along the longer arm. The silicious zone is fringed by a band of ore usually from 20 to 25 ft. in width, and already traced for a distance of nearly 1400 ft. A vertical bore-hole from the main adit apparently proves it to a depth of 514 ft. below that level, and it extends to the surface above, a variable distance, depending on the contours of the country, but probably averaging about 200 ft. The huge tonnage expected from this orebody will undoubtedly be greatly supplemented from other portions of the mineralized area. Workable ores are known to occur at a number of points, but the definition of their extent and quality awaits further exploration.

The mineralized area at the Hidden Creek mine occurs in a larger predominantly argillaceous area surrounded and doubtless underlain, although at a considerable depth, by granitoid rocks, and cut by dikes and stocks belonging to the same period of igneous intrusion. The argillites were irregularly compressed and folded at the time of the invasion, and the deposit probably occupies an area more than ordinarily crushed and fractured, although this has been masked by subsequent alteration and deposition and is not apparent. A wide broken zone, rather than a single fissure, is conceived to have afforded the means by which heated silicious waters carrying iron and copper sulphides in solution ascended from the underlying batholith, altering the argillites in their upward passage and replacing them with silica and sulphides as the pressure and temperature conditions become less severe. An origin of this kind would ally the deposit genetically with the loosely defined contact metamorphic group, although the ordinary contact metamorphic minerals, including the iron oxides, were not observed.

Deposits of the contact metamorphic group, that is, deposits situated on or near the contact of igneous masses with sedimentaries and formed by ore-bearing solutions, either aqueous or gaseous, emanating from the cooling intrusive, vary widely in character. Ordinarily they are described as bunchy irregular masses, made up mostly of iron oxides, and iron, copper, lead, and zinc sulphides, in a gangue of secondary silicates, mostly garnet, epidote, augite, and tremolite. An examination of numerous occurrences at various points along the west coast indicates, how-

ever, that neither shape nor the presence of any or the majority of the compounds mentioned are essential features. The shape is dependent on the channel followed, and in a broken region perfect vein forms produced by the complete replacement of the country between parallel fissure are not uncommon. The constituents are also dependent on the character of the parent intrusive, on conditions of deposit, and possibly on the aqueous or gaseous character of the emanations, and gradations occur from masses of pure or nearly pure magnetite to others made up largely of tremolite and iron and copper sulphides, and in some instances of quartz and sulphides. The present classification, based only on a broad genetic relationship, is far from satisfactory. The name of the group is also misleading, as it includes deposits distant from actual contacts.

Work on the Hidden Creek mine has so far been altogether of an exploratory character, but plans for working and equipping it on a scale commensurate with its importance and for transportation of the ores to the beach are now being made. A smelter will be erected to treat the ores, but the site of this was not decided on at the time of my examination, or at least was not announced. The present equipment includes a power-plant situated on Falls creek and operated by water furnished by that stream, and a compressor and diamond-drill plant.

#### BONANZA GROUP

This group is situated about three-fourths of a mile up Bonanza creek, a small stream emptying into Goose bay about two miles below its mouth. Bonanza creek is a rapid stream about 20 ft. wide, confined in a deep narrow valley terminating below in a rock canyon 20 to 30 ft. deep, excavated since the glacial period. The Bonanza group of claims, six in number, were the first claims staked in the district, and were explored to some extent by M. K. Rodgers before the discovery of the Hidden Creek group. Very little work has been done on them in recent years.

The general character of the deposit on which the claims are staked is similar to that of the Hidden Creek group. The country rock is a dark, somewhat altered, argillite cut by pegmatite and dioritic dikes before it was mineralized, and by a later set of basic dikes after it was mineralized. The argillites are altered over a wide area into biotite and chloritic schists, some of it quite coarse, holding variable quantities of pyrite, pyrrhotite, and in places chalcopyrite. The sulphides are accompanied by some quartz, but this mineral is much less abundant than in the Hidden Creek mine. The altered and mineralized area has a width of over 500 ft., and is opened up by short adits for a distance of 600 ft. along its strike.

The workings consist of three adits, one over a hundred feet in length, north of Bonanza creek; near the creek level, and two adits and some surface work on the south side. The most westerly of the adits north of the creek cuts 10 ft. of granular pyrite near its mouth, beyond which are micaceous schists holding only a small percentage of sulphides. Little copper is present. A sample of the granular pyrite gave on assay 0.48% copper, 1.25 oz. silver per ton, and traces of gold. Some pyrrhotite holding specks of copper occurs in the middle adit. The east adit passes through micaceous schists sparingly mineralized with pyrite. The two adits south of the creek expose schists holding pyrite in scattered grains and bunches, and occasionally some chalcopyrite. Some good-looking chalcopyrite ore is exposed in a cut near the creek, but further exploration is needed to determine whether it occurs in workable quantities or not.

The Bonanza ground looks promising enough to warrant a diamond-drill exploration, such as that in progress with such favorable results in the Hidden Creek property. The area of altered schists carrying iron, and occasionally copper sulphides, is very large, and the present workings cover only a small portion of it. A large quartz vein, fully 10 ft. wide in places, occurs on the North Star claim, one of the Bonanza group. It carries some pyrite and chalcopyrite. A sample assayed yielded only 0.48% copper and 0.20 oz. silver per ton.

# Investigation of Feather River Black Sands

By EDWIN A. SPERRY

In the spring of 1909 I was called upon to make an exhaustive examination of the sands along the Feather river, California, to determine (a) what precious metal content they might have, (b) by what method, if any, the metal content could be recovered at even a small profit. The principal object of the investigation was to determine whether the overburden of sand could be removed from the bars of gravel which apparently formed the original river bed. The investigation extended from Marysville, Yuba county, to a point about six miles above the confluence of the Feather and Sacramento rivers.

The Yuba river flows into the Feather river at Marysville, and has played a large part in depositing the sand. This river was important in the production of gold in the early history of the state, and extensive hydraulic operations were carried on along the gravel bars at Smartsville and other places. These operations filled up the Yuba with debris and by action of the current the sand was carried for considerable distances down the Feather river. The sand lies 20 to 30 ft. deep in places and in no place along the entire 25 miles of river examined was the natural bottom found uncovered.

Some idea may be formed of the immense quantity of sand and gravel which has been deposited in both rivers when it is stated that after a careful estimate of the debris in the Yuba alone, the State Board of Public Works placed the amount at 385,000,000 cu. yd., and, according to rough estimates, it may be stated that there is probably not much less than the same amount in the Feather river which has come directly from the Yuba. The coarser material has, of course, remained in the Yuba, but in places in the Feather, especially near the mouth of the Yuba, the sand is coarse and at times contains much fine gravel. The first work done was to make a fairly accurate survey of the river for the 25 miles under investigation, determining the position of the bars of sand which were to be sampled. After this was planned the work of sampling began. This was done by blocking the bars off in squares (100 to 200 ft. on a side) and sampling at the corners. In some cases the sample was taken for a depth of 6 or 8 ft., by shovel; in others it was taken to considerably greater depth by the use of a sand pump made from a length of brass tubing with a valve at the bottom. This was worked down into the sand and the core for the entire depth was taken.

Each of these samples was thoroughly mixed and cut down to about 5 lb. in weight and put in sacks which were properly numbered. They were then taken to the field laboratory, shown in the illustration, and assayed. Four consecutive samples were usually combined, and as each sample charge was one assay-ton in weight, the results, which, of course, were very small, were weighed from the four assay-ton charge. The assay outfit consisted of a gasoline furnace of the Braun combination type, one set of portable balances consisting of a bead balance sensitive to 1/100 mg., and a pulp balance sensitive to 1 milligram.

At the beginning the reports of the United States Geological Survey were used as a guide in making estimates, and in all these the theory was accepted that the precious metals were associated in direct combination with the black

sand. It was some time before enough evidence had accumulated in sufficiently conclusive form to make the fact clearly manifest that this was not the case. It was almost as a shock that this fact dawned upon us, but when once it did a great many puzzling results and baffling discrepancies were easily correlated and explained. These will be taken up in their proper order.

In the first part of the work the black sand was always taken as a gauge of prospective gold content, and in almost every case this showed quite abundantly. Starting in on the bars immediately at the mouth of the Yuba, the average precious metal held at about 14c. per ton. The content very gradually decreased until at the lowest bar sampled, about 20 miles below, it reached 12½c. The investigation was discontinued at this point, as sufficient quantity and value had been developed to assure many years work in case the sand could be handled at a profit.

After the average content in gold was established the next step was to determine what method, if any, could be adopted to recover it. Naturally the first thing to consider was the possibility of concentrating the sand and by recovering the black sand alone to thus reduce the bulk of the material to where it could be profitably shipped to the smelter. It should be noted that at this stage all experiments and tests were made with the thought in mind that the gold was contained directly in the black sand.

Several average samples of 100 oz. were taken and carefully panned. As a result, it was found that the crude sand was composed of ½ to 1% of black sand (which was very heavy, of course); 2 to 3% of a red sand, which hung between the black and the gray sand; and the gray sand which made up the remainder. In panning, the ordinary pan was used, and each sample was panned three times, making a good recovery of the black sands, but with much of the red sand with it, as it stayed close to and even mingled with the black.

At this point the first baffling results were obtained. In the first case of panning and when considerable red sand remained in the concentrate the value of the concentrate reached \$28 per ton, and the results of several similar tests ranged most erratically between \$4 and \$30. If the sample was panned down to a cleaner product of black sand the content at once fell. The red sand was then isolated and tested and the content shown to be practically nothing. This proved that the red sand held no gold and that the black sand was erratic; or so it appeared from the results. On one trip up the river, along toward the very last of the field work, a bar was found on which had been deposited a bed of clean black sand which afforded a sample of 3 or 4 lb. This was assayed carefully and showed a gold content of less than \$2, which, of course, made much greater confusion.

On finishing up the field work, about 300 lb. of the sand remaining from the original samples was carefully sacked and shipped to San Francisco, where a large amount was treated on a full-sized concentrating table, and the following results were obtained:

In the table below concentrate No. 2 contained a large proportion of red sand which by assay showed but a trace

RESULTS BY CONCENTRATION OF BLACK SAND

Product.	Weight. lb.	Concentration. %	Value.	Extractional. %
Crude sand .....	256	.....	\$0.11	.....
No. 1 concentrate, black sand.....	0.67	367 to 1	26.00	61.86
No. 2 concentrate, black and red sand.....	1.43	178 to 1	6.00	30.47
No. 3 concentrate, red sand.....	3.46	74 to 1	trace	.....
No. 4 concentrate, red and gray sand.....	...	.....	trace	.....
Tailing, gray sand .....	...	.....	trace	.....
Saving in concentrate, No. 1 and No. 2.....	2.10	122 to 1	\$13.00	92.33

of gold. By panning this product it was reduced by 50% as to quantity and increased to \$11 in gold content. Combining this with concentrate No. 1 gave 1.38 lb. of a product which showed a content of \$18.80 per ton, or 89.5% of the total. The concentration then showed a proportion of 185 tons into one, agreeing very closely with the results in the field.

It was at first planned to ship the concentrate to the smelter for treatment, but it was ascertained that the smelting charge was excessive and practically prohibitive. On this, experiments were therefore made to determine the possibility of recovering the gold by the use of some simple and economical method, and as a result the cyanide process was adopted as most closely meeting all conditions. Assay-ton samples were treated in duplicate as a preliminary test, and, basing results on the gold content of the concentrate as \$23.70, the result of a number of assays, the extraction obtained was 71.7% by a 48-hr. contact with a 1% solution. A similar test was made, using 96-hr. contact with a ½% solution, which gave an extraction of 91.5%. In practice, according to general experience, this extraction could prob-

a microscope it was found that the gold occurred in very minute particles apparently well rounded and not scaly but evidently independent.

From this it was supposed that by a system of jigging, the gold, with the finest of the sand, could be brought down into the hutch. A test was made on the bars themselves and a large quantity of material was treated. The result was very disappointing as the screen was somewhat coarser (60 mesh), and about one-third of the sand went through, making but little increase, if any, in the gold content. The method used was to place about 10 lb. of sand on a screen and then to work this in a tub of water much the same as in jigging, washing all the finer stuff through. This being found inefficient, it was next determined to try separation by a certain kind of classifier based on washing the gold out by a strong rising jet. While the classification of the sand as to size was excellent, the gold did not seem to part from the black sand.

It may seem as though the method indicated by the washing test on the screen should have been developed, but it was quite evident that in order to treat the sand in that

ALONG THE FEATHER RIVER.

FIELD LABORATORY.

ably be increased. Owing to the entire absence of cyanides, such as acids, copper, as well as ease with which the solution may be brought in contact with the entire mass, due to its coarseness and uniformity of size, the concentrate presented ideal conditions for economical treatment both in the consumption of cyanide and facility of operation.

Several tests by concentration were made and the results were so erratic that doubts as to the true position of the gold began to be entertained. On sand which assayed almost exactly the same, the gold content of the concentrates varied from \$6 to \$26, and one confusing element was that the cleaner the black sand the lower the content, in the face of the fact that the red sand showed no ascertainable value, usually assaying a trace of gold. One test in particular, where the concentrate was re-run on account of being too dirty, the final product contained about \$6 and was very clean black sand.

This result seemed to be so conclusive that a test was made to see if the gold was not free and uncombined with the black sand. A sample was taken and placed in a 100-mesh laboratory screen and a strong jet of water was directed upon it in such a way as to wash out vigorously all the fine material and thoroughly detach any particles which might be adhering to the coarser particles. The sample taken assayed 20c. gold per ton. It was found that 10% of the sample passed through the screen, and on assay the value of this was shown to be \$2. This may have been merely a coincidence, but was quite sufficient to indicate that the gold was, in point of fact, wholly unattached to the black sand. On examination of a portion of the fine material which passed through the screen by the aid of

manner would probably require expensive methods of handling. It was thought best to work on lines which promise more economical treatment, basing on the probability that in being so very fine it would be easily washed. This and other reasons demanded consideration and prevented following out the first work at that time. When the experiments had reached this stage I was called away, and further experimental work was suspended. As shown by the results of the long series of tests made, it is quite evident, first, that the gold in the sand is free, but owing to a peculiar attraction, or influence at least, the gold and black sand remain closely associated; also that the gold was not heavy enough to sink readily and still not light enough to float easily. Had the financial condition of the company investigating been more substantial, the research would have been carried on to a complete solution, but the results now only indicate what line should be followed. Much time was lost in the acceptance of the erroneous premise that the black sand was in itself of value.

The close association of the gold and the black sand was sufficient to make a first-class showing in treatment on the concentrating table, but of course the capacity of the table was limited, and the question of economical treatment in this way alone was very doubtful. In this the black sand acted as a retainer or carrier, and even then could not be washed extremely clean without danger of washing out the fine gold. In most of the concentration tests the results showed without doubt the possibility of recovering a large part of the gold in this manner at a reduction of bulk to about 1 or 2% of the original amount. This of itself would seem to prove the possibility of isolating the

gold in some way; the question being the economy of the operation, which essentially rests only on the point of the capacity of the devices used.

The erratic results of the concentration can be laid to the unavoidable differences in adjustment of the table which in short runs are bound to occur. In regular running these matters are very easily taken care of, so that it can readily be said that, so far as recovery is concerned, concentration is successful, but as regards economy it is not so well assured. In the one test made by washing through a fine screen, the results were astonishingly good. But there is only the one test to base calculations on, and while it was to all appearance efficient, it is not possible to say with any great degree of assurance that the problem was solved by it. However, the results seem to indicate a line of investigation which might possibly lead to some substantial solution. As the sphere of my activities has been removed so far from the California field, the results of the long and careful, and at times most baffling, series of experiments, can be of no great value to me, but may indicate to others a line of investigation and perhaps a system of operation.

## Errors in the Determination of Moisture in Coal

W. F. Hillebrand and W. L. Badger, in a paper presented before the Eighth International Congress of Applied Chemistry, discuss at some length the determination of moisture in fuels. Methods for moisture determinations in general belong to the class of indirect methods which in the absence of a simple reagent for water are most convenient and expeditious. When applied to so complex and easily oxidized a substance as coal, reactions occur which greatly affect the results. These are classed as follows: The sensitiveness of coal to atmospheric conditions, especially when finely powdered. The loss of volatile substances other than water. The absorption of oxygen directly by the coal substance, by combining with carbon and with hydrogen, splitting off as  $\text{CO}_2$  and  $\text{H}_2\text{O}$ , respectively. The customary practice of coarse crushing followed by air drying, fine grinding, and determination of the remaining moisture. The relation between the air-drying loss and the moisture as determined on the air-dried samples is not constant. Fineness, area of surface exposed, temperature, and especially humidity of the air all affect the results. This is illustrated by a table of results of tests under varying conditions of humidity which illustrate the influence of humidity. In determining the moisture in the ground air-dried sample all the disturbing factors come into play. Four methods were used: drying in vacuum over sulphuric acid; drying for 1 hr. in an oven at  $105$  to  $110^\circ$ ; for 2 hr. at  $105$  to  $110^\circ$ ; and for 1 hr. at  $105$  to  $110^\circ$  in a current of dry air. The first mentioned method gave most uniform results, and the last mentioned ranked next. Tabulated results of tests on six coals are given. In view of the wide discrepancies between different indirect methods, a direct one is desirable. Work has been done along this line, but no definite conclusions have been reached. Some methods which have been tried are: heating coal in a U-tube in currents of hydrogen and nitrogen, and absorption of moisture in sulphuric acid, and weighing. Other methods which may prove of value, and which it is hoped that the Bureau of Standards may be able to consider, are some modifications of the calcium carbide method, and the magnesium-methyl-iodide method of heating in high vacuum and direct weighing of the moisture.

FUSHUN COAL was used experimentally by Korean railway trains for the first time last year, and has proved quite satisfactory. The Fushun variety is somewhat cheaper than the Kyushu coal, and it is this factor which is chiefly responsible for its increased general use. The gold mines operated under foreign management are said to be now using Fushun coal exclusively.

## Japan's Mineral Output

The exact figures of the total value of the production of principal minerals during last year, based on the latest investigation of the authorities concerned, are represented at ¥106,071,000, showing an increase of ¥5,770,000 over the figures of the previous year, and an increase of about twice compared with ten years ago. The following statistics, taken from the *Japan Times*, show the quantity and value of the principal minerals produced last year:

	Quantity, momme.	Value, yen.
Gold .....	1,248,654	6,059,497
Silver .....	36,811,090	4,761,652
	kin.	
Copper .....	88,958,342	27,119,987
Lead .....	6,874,586	506,604
Sulphur .....	83,790,856	1,271,672
	kan.	
Zinc ore .....	6,288,941	806,475
Iron .....	17,032,591	2,575,514
	koku.	
Petroleum .....	1,529,593	6,888,552
	tons.	
Coal .....	17,632,710	55,006,501

The output of gold throughout the country during last year is returned at 1,248,654 momme, valued at 6,059,497 yen. Of the total production Kagoshima prefecture, which is the foremost gold-producing district of this country, heads the list with 1,588,800 yen, closely followed by Ibaraki prefecture with 799,000 yen, Akita prefecture with 737,000 yen, Niigata prefecture with 620,000 yen, Iwate prefecture with 467,000 yen, and Hokkaido with 407,000 yen, the remainder representing the production from various other prefectures.

The total yield of all silver mines the same year aggregated 36,811,090 momme, valued at 4,761,652 yen. The bulk of the output was from the mines in Akita prefecture, which occupies the first place in the silver production of the Empire with the yield amounting to 2,634,000 yen last year. Ibaraki prefecture comes next in order with 364,000 yen, followed by Hyogo prefecture with 273,000 yen, Aichi prefecture with 247,000 yen, and Fukushima prefecture with 205,000 yen.

The production of the two precious minerals shows a marked increase compared with ten years ago. The output of gold last year reached 6,059,000 yen in value, an increase of 53%, against 3,967,000 yen of 1902, and that of silver 4,761,000 yen, an increase of 14%, against 1,936,000 yen of 1902, as may be seen from the following returns:

	Gold, yen.	Silver, yen.
1902 .....	967,590	1,936,753
1907 .....	3,868,755	4,040,431
1908 .....	4,457,430	4,362,740
1909 .....	5,077,058	4,261,481
1910 .....	5,671,806	4,896,188
1911 .....	6,059,497	4,761,652

In the Trebizond region there are 40 copper, 8 silver-lead and copper, 2 lead, 3 antimony, 8 lead and copper, 1 copper-zinc, 2 manganese, 1 copper and coal, 2 coal, 5 copper-silver, 3 silver-lead, 1 silver, 4 iron-lead, and 1 iron-arsenic mines reported within 2 to 30 hours distance from the coast. Only 14 of these have *firmans*, the others holding permits only, and no serious work is being done in any of them. The owners expect to find capitalists who will buy their mines.

DREDGE No. 10 of the Natomas Consolidated is reported to have cleaned up \$16,500 as a result of eight days run while operating in gravel containing 61c. per yard, digging to a depth of 30 feet.

# The Major Mines

By A. W. GEIGER

The Major mines lie about seven miles southeast of Baguio, the chief town of the province in Benguet, about 150 miles north of Manila, in the island of Luzon, Philippine Islands, and are reached by a good road which winds through the hills along a general descending grade. The elevation at the Major mine main camp is 4000 ft., or about 1000 ft. lower than the Baguio bench-mark. The property consists of 17 mining claims, each 300 metres square, forming a contiguous group, but naturally divided by topographic conditions into two parts, those claims on Major creek and those across a high ridge to the north. All the work of consequence has been done on the Major creek side, where there are several large veins showing considerable mineralization. The three principal ones are called the Vidette, Dan J., and Engineer. They outcrop very plainly in the creek and have the appearance of strong veins; the general strike is N.45°E. and dip to the northwest 30 to 60°. The development consists of

occur as (1) fissures in the andesite, (2) along the contact of the andesite with the sedimentary shales, and (3) in cracks and spaces along the bedding planes of the shales.

The fissure veins in the andesite are big soft leads, as a rule, with some vein-quartz filling, but extensive silicification, impregnation, and softening of the wall rock. It is difficult to determine the limits of the true vein. The mineral content is irregular, and in places extends a considerable distance into the softened wall rock, making small kidneys of good ore, caused by local enrichment at these favorable places. This is easily mined, but the ground is heavy and there has been difficulty in holding it during the rainy season. The ore is soft and oxidized, with much kaolin, often with pyrite, as much as 5%, and small amounts of galena, chalcopyrite, and zincblende; it yields about 70% of slime in milling, and the cyanidation necessary to make proper saving must be by agitation methods. The free gold is as fine as mustard generally, and care must be exercised in amalgamation. Generally not over one-third of the gold can be saved on the plates.

These large soft veins and impregnated zones in andesite are characteristic of the ore deposits of the Benguet district. The contact veins and mineralization along the

DAN J. WORKINGS, MAJOR MINES.

VIDETTE WORKINGS.

numerous adits, aggregating 1500 ft. of work, most of which has been poorly directed. The greater part of the work has been done on the Vidette vein, and consists of five adits with the uppermost about 400 ft. higher than the lower at the creek level. Several shoots of workable ore have been found, but nothing very extensive as yet. In the upper workings, known as the Long Horn, there is a well defined ore-shoot which has been developed for about 40 ft. on the dip and 50 ft. on the strike. This shoot is not developed to its limit and extends beyond the present workings dipping to the northeast. A considerable amount of ore was milled from this pocket, and the results indicated a gross assay-value of \$12 per ton. Of this amount, not over one-third was saved, and on account of expensive mining and tramming methods the company did not make a profit in the working of this ore.

## GEOLOGY

The prominent formation of the Major area is an andesitic eruptive varying from a true andesite porphyry to a more holocrystalline rock resembling diorite; these changes in texture are frequent and due to differences in rates of cooling of the eruptive, largely influenced by the successive flows which have occurred here at different periods. Included in the andesite there is present an extensive series of sedimentary rocks which are well exposed in Major creek for a thickness of over 1000 ft. and extend to the southwest over the high ridge above the Major ground and into the Benguet road, where they are again plainly visible. They consist of lime shales and conglomerates, and have been tilted to an angle of about 45°. The Major deposits vary greatly in character. The veins

bedding planes of the shales appear to be the most important type at the Major, although not characteristic of the Benguet district. These deposits are very irregular, the leads splitting up and coming together in bunches, often of considerable size. The ore in the shale is very hard and contains as much as 8% sulphides, principally pyrite. The gold is quite coarse, and often specks of it are visible in the ore, principally in the numerous small quartz seams filling cracks in the shale. The content is irregular and there are wide differences in assays of adjacent samples. The Long Horn ore-shoot, already mentioned, is of this type, and represents the most important development on the property so far.

All the workings at the Major are above the primary ore-zone, and in fact this is true of all the work done in the district. The rapid erosion of this area keeps pace with the oxidation, and that zone is very generally of shallow depth. In the oxidized zone there has been extensive concentration by secondary enrichment and mechanical concentration. At many places in the veins there are streaks and spots where samples taken show considerable value. In prospecting over this area with mortar and pan, one may be unduly influenced by the many samples that show a lot of fine free gold. The former management of the Major mines attempted to work the numerous small bunches of enriched surface material, with the result that there are widely scattered workings and a complicated expensive system of trams for getting the ore into the mill.

The milling plant consists of a 6-stamp Hendy mill, with individual mortars, quadruple discharge, and having

1000-lb. stamps, crushing through a 30-mesh punched screen. The equipment includes an 8 by 10 jaw-crusher, grizzly, 50-ton ore-bin, automatic feeders, two amalgamating plates, and mercury traps. The power is furnished by boiler and 50-hp. engine using wood fuel. The cost of the wood in the past has been only about \$4 per cord for 3-ft. wood. It is cut by the Igorrotes under contract.

Below the plates there are two Willley No. 6 sand tables, followed by cyanide leaching plant. This consists of six vats, 20 by 5 ft., arranged for filling with Butters distributors. A stock tank, sump tank, 10 by 16, zinc-box, piping, and other accessories complete the equipment. It is all housed in and well situated for protection from the *baguios*, which is most important in this district. An electric-light plant was installed for lighting the mill and manager's house.

The method of treatment for the Major ore was marked out in detail by the California Ore Testing Co., of San Francisco, and it was shown conclusively that over 90% of the content could be saved by amalgamation, concentration, and cyanidation, and about equal amounts by each method. The difficulties are that the concentrate recovered is not high-grade enough to permit of marketing in San Francisco, and tests made tend to show that the sulphides cannot be satisfactorily cyanided. The possible solutions of this problem are: (1) The reduction of the freight rate to water transport, on the completion of the railroad now building into Baguio; (2) by roasting and smelting in small reverberatory-furnaces with silicious high-grade ores, a fire method of concentration may be developed; (3) by chlorination methods in connection with other small mines of the district. This question of rendering the values in the concentrate available at low cost is the only difficulty in the metallurgy of these ores.

A total of \$100,000 gold has been expended in the exploitation of these Major mines, and it furnishes a striking example of the things that ought not to be done in a new mining field. The deposits have not as yet even been prospected, as there has not been any development work done at any considerable distance from the surface. The mill and other expensive improvements were installed without any knowledge of the extent and value of the ore deposits.

## Reducing Conveyor-Belt Costs

In a belt-conveying system, the largest single item of expense is the belt, and large users of this machinery devote considerable study to this part of the equipment. The original cost of the belt constitutes from one-third to one-half the cost of the entire conveyor, increasing with the length of the conveyor. Belt renewals are also the largest item of up-keep, this cost varying according to so many conditions that no general rule can be laid down. There are, however, certain general principles covering machinery of this type, and proper observance of these principles may greatly reduce the cost of operation. In analyzing the causes of belt wear, we will consider first the wear caused by the material carried and, second, external causes. The material produces wear by (a) slipping on the belt due to its inertia at the loading chute, (b) slipping back on the incline of the conveyor, and (c) by rearranging its position on the belt between the loading and discharge points.

The first can only be overcome by delivering material to the belt at the belt speed. The chute should be inclined in the direction of the conveyor's travel so that the material may receive a certain impetus before it strikes the belt. A curved lip is sometimes advocated at the bottom of the chute, but this arrangement is usually impractical and does not greatly reduce slippage. A more effective arrangement used under certain circumstances is to fit a V-shaped lip to the chute or a perforated plate which allows the fine material to drop upon the belt first, and then the larger lumps fall upon the fine material.

The second cause may be entirely overcome. On a properly designed conveyor, there should be no slippage whatever on the incline. For most materials the maximum inclination used should be about 20°, although this is sometimes exceeded under certain conditions. In all cases it should be as a minimum 10° less than the angle of repose of the material on the belt. Lumpy material has a tendency to roll back on the belt, unless intermixed with fine, and also an intermittent flow allows more slippage. All these conditions should be taken into account before determining the operating angle.

Rearrangement of the load is greatest in a deeply troughed belt and is reduced to a minimum on a flat belt. The present tendency is, accordingly, to use a very shallow trough. At the present time 20° is usually the standard practice, whereas from 30 to 45° was common several years ago. The change has been made without perceptibly reducing the capacity, but with a great saving in belt wear. It is often well, however, to use deeply troughed carriers beneath the chute, one placed about 3 in. behind the point of loading and two others closely spaced beneath the skirt boards.

The proper alignment of the carriers is always important in order that the belt may run perfectly true. This may be done by leaving one side of the carriers only partly tightened. Then, by running the conveyor empty, any tendency of the belt to run to either side may be corrected by tapping the carriers either forward or back. By going over them in this way, several times, the belt may be adjusted to run centrally and the carriers should then be tightened. Neglect to observe this precaution allows the belt to run against the guide idlers, and the sides of the chutes, thus rapidly wearing the edges of the belt.

Another point to be considered is the action of the weather. The sun's rays are as detrimental to rubber belts as to rubber tires, while rain, snow, and ice are all injurious. Water may get between the piles and rot the fabric, or may freeze and force the piles apart. In some cases, where no covering is provided, the belts are taken from the conveyor during the winter, but the best results may be secured by providing a permanent housing.

A steady feed is important, especially for an inclined conveyor, and it is good economy to provide an automatic feeder with all installations. Another very important consideration is the type of carrier used. The carrier must be constructed so that the pulleys will revolve freely in all weather, and under all conditions, so as not to offer more resistance to the belt than is absolutely necessary. A ball-bearing carrier has practically no wearing effect upon the belt, and it usually pays to use such a carrier, even at an increased cost. The strength of the carrier should also be taken into consideration, as a broken pulley can sometimes greatly injure or even ruin a belt. By a careful observance of these principles, good service can always be secured from high-grade belts.—*The Labor Saver*.

SAND is the main constituent of glass, forming 52 to 65% of the mass of the original mixture, or from 60 to 75% of the finished product after melting has driven off carbon dioxide and other volatile materials. On the quality of the sand depends the transparency, great brilliance, and hardness of glass. Generally speaking, sand should not contain more than 0.2% of iron oxide when used for making good glass. Pennsylvania produces 30% of the sand used in glassmaking in the United States, about 400,000 tons, the average value being \$1.40 per ton.

THE Government Water Supply Department, now furnishing water to the Kalgoorlie mines at \$1.68 per 1000 gal., is charging the Mountain Queen, near Southern Cross and 140 miles nearer the Mundaring weir, \$2.40 at the Marvel Loch stand-pipe, from which it must be carted, and \$5.40 if delivered to the mine by pipe-line. The mine uses 200 gal. per ton treated, so it costs \$0.48 per ton for water at the stand-pipe, and the whole cost of milling, including carted water, is \$1.

# Recent Advances in Industrial Chemistry

By RAYMOND C. BENNER

Advances in modern science are so rapid that it is out of the question for anyone but a specialist to keep abreast of the times. In fact, time after time, even those of us who make it a business to keep up on a particular subject, find that important things are missed, so vast is the volume of literature to be reviewed. Therefore, it is not amiss to give a brief review of some of the more important discoveries of the past few years.

## METALLIC ELEMENTS AND ALLOYS

Probably in no branch of applied chemistry has so rapid an advance been made as in the isolation of the rarer elements in a pure state and in making alloys of them with the more common elements. As a matter of fact, the properties of the alloys, in many cases, differ so radically from the original elements entering into the combination that, to all intents and purposes, so far as the physical properties are concerned, they act like a new element. There seems to be an alloy with properties suited to each special purpose.

Tungsten, tantalum, molybdenum, and boron have yielded to the efforts of the chemists and are now to be obtained in the pure state in the open market. The high melting points, together with high electric resistance of tungsten (3100°C.) and tantalum (2300°C.) make them especially valuable for the filaments of electric lights. The efficiency is thus increased to such an extent that the statement is frequently made that, at the present price, the consumer can afford to buy a tungsten lamp rather than have a carbon lamp given him. The most recent progress in the metallurgy of these interesting elements has been in the obtaining of them in a ductile form. Tungsten, tantalum, and molybdenum wire can now be purchased on the market. Formerly, in the manufacture of lamp filaments, it was necessary to form the metallic powder into a paste with some plastic substance, squeeze it through a die, then drive off the binding substance by means of the current and at the same time fuse the metal into the form of a wire, but now that the secret of obtaining these in a ductile form has been solved the wire can be drawn.

The extremely high melting points, combined with the high electrical resistance of these elements, makes them of special interest to all laboratory workers, because of the possibilities in the way of wire-wound resistance furnaces for high temperatures. Temperatures considerably higher than with a platinum-wound furnace can thus be obtained. It is possible to make furnaces wound with tungsten wire in a manner similar to that in which any other wire-wound resistance furnace is constructed, with the one exception that, as these elements are readily oxidized, they must be kept in an atmosphere of hydrogen during the time of heating.

Boron has recently been obtained in a very pure state by Weintraub in the laboratories of the General Electric Co., and has been found to possess many interesting as well as valuable properties. Iron, although one of the most common of the useful elements, has been until recently one of the hardest to obtain in a pure state. Among the elements utilized for the manufacture of commercial alloys there are few, if any, which are more affected by very small amounts of impurities. It has been found possible, for some time past, to remove nearly all of the impurities from iron by various means; but not until Franz Fisher electrolyzed an iron salt at from 100 to 120°C. in the presence of some hygroscopic salt, such as  $\text{CaCl}_2$ , was it possible to obtain iron free from hydrogen, which rendered it hard and brittle. On the removal of the last traces of hydrogen, iron becomes softer than gold and silver, and not much harder than aluminum. Pure iron possesses the valuable property of becoming magnetic more quickly and again losing its magnetism much more rapidly than when

it contains carbon and silicon, thus making it about  $2\frac{1}{2}$  times as efficient for use in electric motors.

The development of the electric furnace in the metallurgy of steel has solved the problem of the removal of the sulphur and the production of a slag free from metal. The electric furnace for this purpose is in use in a number of places in Europe and America, where the electric power is obtainable from water power and sufficiently reasonable in price. It may not be out of place to mention here that it has recently been found possible to economically remove practically all of the sulphur from iron ore by roasting in some of the more modern furnaces.

The ease with which nickel forms an alloy with iron has been known for a long time, but on account of the impossibility of obtaining nickel in a pure state, the alloys have until recently been but little used. The same fact holds with many alloys, more especially with those of chromium, silicon, and manganese with iron. The most important object in manufacturing a successful armor-plate is to obtain a tough non-crystalline structure. This is accomplished by the removal of more or less carbon and by subjecting to a peculiar heat treatment (suddenly cooling when at high temperature, heating again, and keeping at a certain lower temperature for some time). The nickel-steel sheets are two or three times as hard as welded iron, have a tensile strength of 55 tons per square inch, and are much less easily fractured than ordinary steel. Alloys containing 23% and more nickel are non-magnetic. Those containing over 30% have a high resistance to electricity, while those containing 45% have a coefficient of expansion about one-twentieth that of steel.

Chromium, tungsten, and molybdenum form alloys which are of interest to the chemist and metallurgist because they are very resistant to chemical reagents, and because variations in the heat treatment likewise cause this resistance to vary greatly. It can be increased as much as five times in this manner. Alloys have been made which are insoluble in dilute hydrochloric, sulphuric, and nitric acid. An alloy containing 60% chromium, 35% iron, and from 2 to 3% molybdenum is said to withstand the action of boiling aqua regia. The use of these elements for special self-hardening tool steel, which makes possible the running of the lathe tool nearly to a red heat without softening, is familiar to all.

The use of vanadium in steel for special alloys would increase much more rapidly—as it is very useful—were it possible to obtain it at a more reasonable price. Krupp is said to have recently patented a remarkable alloy which cannot be drilled, exploded, nor cut by an oxyhydrogen blowpipe. The hard manganese steel invented by Robert Hadfield is used for castings and, although not malleable, can be bent in a cold state without breaking. It thus forms a useful alloy.

## NON-METALLIC ELEMENTS

The conquest of the air by the chemist forms one of the greatest triumphs of the last decade. Although the fact that oxygen and nitrogen can be made to combine by means of an electric discharge, has been known since the time of Priestley, it remained for Birkeland and Eyde to commercialize it. The NO formed by the union of the O and N when exposed to the excess O in the air forms  $\text{NO}_2$ . This gas, when brought in contact with water, forms  $\text{HNO}_3$ , liberating NO, which is then capable of forming more  $\text{HNO}_3$  in the same way as before. The dilute acid is concentrated to 50% acid in the absorption towers, when it is sold, used to neutralize with  $\text{CaCO}_3$ , forming  $\text{Ca(NO}_3)_2$ , or as a basis for the preparation of other compounds.

Caro has found that where calcium carbide is heated in the presence of nitrogen,  $\text{CaCN}_2$ , called cyanamide, is formed. The nitrogen of the air can thus be caused to

enter into chemical union, in a form available for agricultural purposes and for the extraction of gold. The world's production now approximates 200,000 tons. Ammonia can be prepared from this substance by treating under pressure with steam.

One of the most striking results of scientific investigation is the method of making synthetic ammonia from the elements. It is a well known fact that the affinity of nitrogen and hydrogen is so small that they do not unite appreciably with one another, either at ordinary or at a raised temperature. Many chemists have worked on this synthesis, but it remained for Haber to devise a successful process of circulating a mixture of nitrogen and hydrogen, over iron as a catalyte, at a temperature of 650 to 700°C. and under a pressure of 200 atmospheres, the ammonia being removed from the cycle by means of absorption in water.

#### INDUSTRIAL PROCESSES

The need for a good process for the recovery of tin from old tin-plated ware has given rise to a new method which takes advantage of the property of chlorine gas in a dry state to act upon tin, and not on iron, between certain temperatures. By this method a very pure form of anhydrous chloride is obtained instead of impure tin mud, as formerly by means of the older electrolytic process.

Among the new compounds which have been developed within the last few years are the peroxides, percarbonates, perborates, and persulphates. Peroxide of hydrogen, formerly sold only in water solution, has been found to form a crystalline compound with urea, which makes it possible to buy this useful oxidizing agent in solid form for hygienic and pharmaceutical purposes. There is also the new industry of making true artificial gems, which do not vary in chemical composition from those found in nature. These can now be made because of the ease with which high temperatures are controlled and used. Artificial rubies, and white, yellow, and blue sapphires are made by coloring fused alumina by means of chromium oxide, iron oxide, or titanium oxide.

Last but not least, is the successful outcome of a long series of experiments by W. H. Perkins upon the permanent fireproofing of cotton goods, more especially that commonly called cotton flannel, so widely used for children's garments, which is especially inflammable, burning with great rapidity. It has long been known that this purpose is temporarily accomplished by impregnating the cloth with such solutions as a mixture of three parts ammonium phosphate, two parts aminom sulphate, and forty parts water, or a solution of sodium tungstate. But these, together with some thousands of other mixtures, give only temporary results; for the substances used for impregnating the fabrics are soluble and, not becoming fixed in the fibre of the cloth, are dissolved out after two or three washings. It was finally discovered, however, that cotton goods become permanently fireproof and that the tensile strength of the goods increased some 20% by the following process:

"The material is put through a solution of sodium stannate of about 45°Tw. in such a manner that it will become thoroughly impregnated. It is then squeezed in order to remove any excess of the solution, and passed over heated copper drums to dry it perfectly. It is now run through a solution of ammonium sulphate of 15°Tw., again squeezed, dried, washed, and finished in the ordinary manner."

**ZINC SMELTING IN JAPAN.**—The Mitsui Bussan Kaisha is erecting a zinc smelter at Omuta, near the coke plant, to refine the ores from its zinc mines. At present the ore is shipped to Europe, and the refined zinc imported. The new smelter will therefore effect a saving in the cost of zinc and will also stimulate the development of mines heretofore considered unprofitable. Another company has recently been organized at Osaka to engage in smelting and refining zinc. These two zinc smelters are the only ones in Japan at present. The total import of zinc into Japan is about 4000 tons per year, valued at \$500,000,

of which amount 10% is imported into the Nagasaki district. The local consumption is more than the capacity of these two companies' plants, and if they prove successful in operation they will have a market for their entire output. The chief zinc mine in Japan is the Kamioka, in Gifu prefecture, Kyushu, which produced about 9000 tons in 1908. This property yields copper and silver as well as zinc.

### International Map of the World

The first sheet of the United States portion of the international map of the world has just been issued by the United States Geological Survey, and includes Rhode Island and portions of New York, Connecticut, Massachusetts, New Hampshire, Maine, and Nova Scotia. This world map, recently undertaken by the leading nations, is being prepared on the scale of 1 to 1,000,000—that is, 1 linear inch on the map represents 1,000,000 inches, or nearly 16 miles, on the earth's surface. The map is to consist of about 1500 sheets covering all the land areas of the world, each sheet representing 4° of latitude and 6° of longitude. The sheets will be numbered according to a scheme covering the whole world, and the symbols indicating the natural features and the works of man will be uniform on all the sheets. It has been the dream of geographers for many years to have an international map scientifically constructed on a uniform scale, and the work is now well under way. The maps at present available, printed on all sorts of scales, in geographies and atlases, where the most important areas are allotted the greatest space, inevitably lead to misconceptions as to the relative size of the different countries. Thus it is not generally known that the area of England, Scotland, and Ireland together is less than that of any one of our five largest states; or that Texas is much larger than France; or that the new states of New Mexico and Arizona are each larger than the combined areas of the Balkan countries of Bulgaria, Rumania, Servia, and Montenegro, now engaged in war with Turkey; or that Argentina is more than three times the size of the thirteen original states. With an international map on a uniform scale the study of comparative geography will become far more fascinating and instructive.

At the present rate of progress the United States portion of the international map should be finished within eight or ten years. It will be by far the best map of the country in existence. There is, in fact, no very accurate map of the United States as a whole, although the Geological Survey publishes a base map about 7 ft. wide, and the General Land Office has issued a similar map. Most of the commercial maps, though pretty to look upon, are full of gross errors. For a superficial study of the country the ordinary maps may serve the purpose, but when one finds a town 5 or 6 miles out of position with reference to a railroad or some other town he realizes that the present-day geography or atlas map is anything but accurate.

The Geological Survey has topographically mapped in great detail more than one-third of the United States, but these maps are mostly on a scale of 1 mile or 2 miles to the inch and are too large for ordinary comparative purposes. The Boston sheet of the millionth-scale map is a very accurate map and is a beautiful product of the engraver's and lithographer's art, printed on fine enameled paper. This sheet is sold by the Geological Survey at the bare cost of production, namely, 40c., which will be the price of the other sheets as issued. Thus the entire map of the United States will cost \$20.80. As a preliminary to the issuance of the completed color sections of the United States portion of the world's map the Survey is printing, in black and white, state maps on the scale of 1 to 500,000, being thus four times as large as the world's map of the same area. Already such maps have been finished and printed for Vermont, Illinois, Indiana, Iowa, Minnesota, Mississippi, and Georgia, and a dozen others are in process of publication. These are sold by the Survey at varying prices according to the size of the maps. For instance, the Vermont map is sold at 10c. and the Minnesota map at 40 cents.

## Safety Device for Skips in Inclined Shafts

From time to time serious accidents occur in inclined shafts through the rope on a skip breaking, brakes refusing to act on hoisting engines, or the safety device on the skip not acting in time. At Mount Morgan, in Queensland, a safety man car was devised, and interesting details have been given in a paper prepared by N. F. White, T. R. Dibdin, and P. Drain for the Australian Institute of Mining Engineers, from which the following is abstracted.

The safety device finally adopted completely fills the two conditions of coming into action independently of the position of a fracture in hoisting rope, in the event of the rope unreeling from the drum due to the latter getting beyond the control of the engineer, and operating

POSITION OF TOGGLE-STOP WHEN HOLDING CATCHES CLEAR OF GUIDES.

at an adjustable speed limit, being actuated by centrifugal force derived from the rotating car axle. This safety gear is essentially a shaft governor, and remains fixed until a predetermined speed is obtained, when it operates instantly.

The man cars at Mount Morgan are provided with a device which is a combination of four main parts: (1)

catch is set, it is clear of the hinged hooks. Should the rate of rotation exceed the proper speed limit, the hooks move radially outward and strike the trigger-arm, thereby moving the trigger clear of the spring-actuated drop catch, which then rotates into such a position that a hinged hook engages with it. The hinged hook now being engaged with the spring-actuated drop catch, the loose disc also rotates. Attached to the back of the loose disc is a knocker, by which the toggle-stop is operated. (3) The toggle-stop consists of two main members, hinged together by a pin. This pin is prolonged to form a handle with which the toggle-stop may be set or removed. The main member has

FACE VIEW OF FIXED DISC.

a prolongation called the toggle horn, which is struck by the knocker attached to the loose disc. When the toggle-stop is set, the main member rests against an adjusting screw. (4) The car is fitted with two sets of catches, which are connected together by a bar and four links in such a manner as will make them move simultaneously. Each

ELEVATION, SAFETY MECHANISM OF MAN CAR.

hinged rotating hooks, (2) trigger and drop catch; (3) toggle-stop, and (4) spring-actuated catches. Of these the duties are as follows: (1) Fixed rigidly to the forward axle is a disc, to which are attached two hinged hooks, each being fitted with an adjustable retention spring. Projecting from the face of the fixed disc are 'outer' and 'inner' limit pins. The hook springs maintain the hinged hooks in continual contact with the inner limit pins until the working speed limit is reached. The outer limit pin prevents the hinged hook from flying completely out, should the hook spring break. (2) Loosely riding on the same axle to which the fixed disc is attached is a second disc, the loose disc carrying a trigger and spring-actuated drop catch. The trigger has an arm which passes through, and beyond the loose disc, by means of a slot. When the drop

set of catches is provided with a powerful spring, whose total tension is about 3000 lb. when the catches are fully opened, and about 1000 lb. when on the point of gripping the guides.

The setting gear, by means of which the catches may be opened clear of the guides, is plainly shown in the accompanying illustration. To render the mechanism entirely independent of any person, suitable gear to automatically disengage the setting gear is provided. The action of the gear is as follows: When the velocity of the car exceeds the predetermined limit (450 ft. per minute at Mount Morgan), the centrifugal force of the hinged hooks overcomes the tension of the hook springs, and the hooks move into a position where they strike the trigger-arm, and thereby move the trigger a short distance, thus dis-

engaging the drop-catch. The spring-actuated drop-catch being released, rotates into a position where a hinged hook may engage with it. The hinged hook being engaged with the drop-catch, the loose disc rotates and carries with it the knocker. The knocker striking the toggle horn drives the toggle-stop into the 'off' position, whereupon the catches engage the horizontal guides, bringing the car to rest. Operation by hand may be effected by pulling an emergency lever, whereby the toggle-stop is driven into the off position. This type of car was thoroughly tested by severe tests, and is in use at Mount Morgan where the grade is 1 in 3. The shaft has two compartments, each with 26-in. gauge track laid with 30-lb. rails. The dimensions of the car are: length over all, 18.5 ft.; width, 4.25 ft.; width of seats, 1 ft.; height of seats, 1 ft.; width of foot plates, 18 in.; wheel base, 6.25 ft.; weight of empty car, 4480 lb.; seating capacity, 18 men.

## Gold Production of Western Australia

The July gold output was valued at \$2,059,100, the principal returns being as follows:

	Tonnage.	Yield.	Profit.	Div.
Gt. Boulder Proprietary	19,069	\$235,400	\$122,100	.....
Ivanhoe .....	20,836	204,200	80,000	\$225,000

WHEN at the end of last year the Consolidated Gold Fields of South Africa absorbed the Rhodesia Exploration & Development Co., it was generally understood that Sir Abe Bailey had retired from the arena of Rhodesian mining, or at any rate, that he ceased to be an active factor in the mineral industry of the country. When he left South Africa a few months ago for England, he was faced with complex lawsuits in regard to certain 'deals' with the Amalgamated Properties Co., and it was generally understood that he had disposed of all his holdings in the country. It seems, however, that Sir Abe proposes to re-enter the field. Advice from London state that he has obtained control of the London & Rhodesian Mining & Land Co., which owns several important mining properties in Mashonaland, notably the Cam & Motor (which promises to become one of the largest mines in the territory), the Hay, and others. In Salisbury it is rumored in usually well informed circles that Sir Abe Bailey, Hans Sauer, and H. G. Latilla (the three chief factors in the now defunct Rhodesia Exploration & Development Co.) are busily engaged in forming a new and large company for the purpose of exploiting mineralized and agricultural properties in Charterland. Whether this

refers to a reconstruction of the London & Rhodesian company or not remains to be seen, but it is now clear that Sir Abe and his colleagues have by no means retired from the zone of activity in the northern territory.

## Preparation of Metallic Tungsten

The preparation of tungsten from its ores has been described by G. Erhard in *Metallurgie*. If bismuth is present in the ore in sufficient quantity, it is first extracted by crushing, roasting, and leaching with HCl. The dried residue is then heated with carbonate of soda, using 60% excess over the theoretical amount necessary to produce sodium tungstate. After the charge is sintered it is cooled, crushed in a ball-mill, and again sintered. The second sintering increases the extraction from 70 to 97%. The sintered charge is leached in iron vats with hot water. Steam may be introduced to keep the water hot. The solution is evaporated until crystals of sodium tungstate separate, and are skimmed out. It is difficult to keep the crystals from forming on the sides of the kettle and burning fast. The sodium tungstate is decomposed by salt and 6% of nitric acid into tungsten trioxide. The tungsten trioxide settles on the bottom of the vat in a hard mass and is removed with difficulty. The fumes from the reaction are caught in an absorption tower. Care must be taken to prevent contact with iron while the tungsten trioxide contains acid. The dried tungsten trioxide is heated with 14 parts charcoal and 2 parts colophonium, thus reducing it to the metallic state. The metal is mixed with some reducing material and undecomposed tungsten trioxide, from which it is freed by crushing and washing.

## Stream Flow in California

The material progress of California has in large part been measured by its water-supply development. In the days of forty-nine its first great boom was the result of finding gold in a creek bottom, and throughout the early gold days the rapid growth of California was made possible by the development of water supplies for use in placer mining. In later years came the great irrigation activities, and especially in southern California have the agricultural products become so valuable that in that part of the state water is probably worth more than it is anywhere else in the country.

Throughout the Sacramento and San Joaquin valleys water has the same relatively large values for irrigation. Still later came the recognition of the enormous importance of California water-powers. In a very few years the development of water-power has grown until California ranks second only to New York, the total horse-power in the state in the year 1911 being over 500,000.

It is apparent that in a State so thoroughly dependent upon its water supplies, investigations which will reveal the amount of water available in the streams and beneath the ground are of the highest importance. The people of California have recognized this, and for many years have through their legislatures cooperated with the United States Geological Survey in the determination of stream flow and the location of underground supplies.

The Geological Survey has just issued Water-Supply Paper 291, on the surface water supply of the Pacific coast in California, 1910, by W. B. Clapp, F. F. Henshaw, and H. D. McGlashan. This report contains the results of measurements of some of the California rivers, made during the year 1910, at regular stations maintained by the Survey in cooperation with the office of the state engineer. All the important rivers of the state were covered in this investigation, and in addition many of the smaller tributaries and irrigation canals. There are in all 98 stations from which data are reported in this publication, and work has been carried on in a way that affords for almost every stream reported a daily record of the discharge.

## Value of the Spanish Arroba

By ROBERT FRAZER, Jr.

Investigation shows that the Spanish arroba varies in almost every province, and in some cases, as in Valencia, there are several different arrobas. That of the province of Castile contains 25 Spanish pounds of 16 oz. (the Spanish *onza* (ounce) contains 28.755 gm., the *avoirdupois* ounce 28.3495 gm.), and is equivalent to 25.358 United States pounds; but a table of equivalents published in Valencia gives no less than five different arrobas used in the province of Valencia—the 'common arroba' of 36 lb. of 12 Spanish ounces, the 'lesser arroba' of 30 lb. of 12 oz., the 'flour arroba' of 32 lb. of 12 oz., the 'fish arroba' of 24 lb. of 18 oz., and the 'lead arroba,' of approximately 32 lb. 4 oz., used in weighing that metal. The table referred to gives the 'common arroba,' which is now the only one much used here, as equivalent to 12.355 kg., or 27.238 lb. U. S.; but as the metric system is the only one now legally recognized in Spain, the term 'arroba' seems to have come to mean in common parlance, certainly in Valencia at any rate, an eighth of a metric quintal, or 12.5 kg. (approximately 27.5 lb. *avoirdupois*) instead of the 12.355 kg. it originally represented.

## Copper Producers' Association Report

The Copper Producers' Association statement, November 8, shows an increase during the preceding month in accumulation in this country of 13,679,380 lb. The details are as follows:

	Pounds.
Stock of marketable copper of all kinds on hand at all points in the United States, Oct. 1, 1912	63,065,587
Production of marketable copper in the United States from all domestic and foreign sources during October	145,405,453
Deliveries for consumption, October	84,104,734
Deliveries for export, October	47,621,342
Stock of marketable copper of all kinds on hand at all points in the United States, November 1.	76,744,967
The changes in surplus since November 1, 1911, have been as follows, in pounds.	
	Increase.
November, 1911	23,212,454
December	22,330,493
January, 1912	22,173,252
February	3,301,944
March	572,431
April	2,927,829
May	15,450,386
June	5,280,639
July	5,945,416
August	3,579,046
September	16,364,213
October	13,679,380

THAT portion of the international geological work along the 141st meridian (the Yukon-Alaska boundary) which had been undertaken by the Canadian Government, the United States and Canadian Geological Surveys having agreed to map the geology along the boundary line from Yukon river to the Arctic Ocean, a distance of about 350 miles, is now finished. This work was commenced in the spring of 1911, and by the terms of the agreement the United States and Canadian geologists worked to the north and south respectively of Porcupine river, each extending their investigations at least two miles east and west of the boundary line. This work not only gives a geological section at that longitude through the northern half of the Yukon plateau, the entire Rocky Mountain, and the Arctic slope physiographic provinces, but should also assist materially in correlating the geology of Alaska with that of Yukon and British Columbia, both in Canada.

## Copper Review for October

By MISHA E. APPELBAUM

During the past month the main sellers of copper have adhered to a price of 17¾c. Due to the Balkan war situation, the London Metal Exchange exhibited irregular and at times weak tendencies, which resulted in large sales by the dealers to consumers, principally at lower quotations. While domestic consumers purchased some copper during that period, Europe practically remained out of the market. As soon as the result of the election became known, copper on the London Metal Exchange exhibited very strong tendencies, scoring a smart advance, with the result that even the dealers' prices were advanced about ¼c., bringing them up almost to the producers' prices.

It must, however, not be overlooked that in spite of the increase for the past two months in the visible supply in the United States that in Europe has decreased largely and that the statements for the next few months on this side will reflect the reduced output due to the strike situation in Utah and other States, so that by the first of January, or February at the latest, there will be much less copper on hand than at any time since 1907. In trying to diagnose the course of future prices one must, of course, be guided by the business situation, which at the moment is in an exceedingly healthy state. I, for one, do not believe that the tariff or trust legislation which will be attempted by the Democrats will be of such a drastic nature as to paralyze business or even to interfere with the improvement in business which has been going on steadily. If, therefore, I am correct in my assumption that the business improvement will continue and that the Democrats will seize the opportunity which has been given to them for the first time in over sixteen years by advocating conservative and proper legislation, then I do not hesitate to go on record in stating that by the beginning of next year, copper will sell at much higher prices than at any time since 1907. In fact, this opinion applies to all metals.

## Gold-Mining in Antioquia, Colombia

By LOUIS A. MAIRE

At Amalfi, an American company under G. B. O'Brien, has some ground suitable for working by hydraulic methods and is running a long bedrock tunnel about 1000 ft., preparatory to commencing operations. Production at this property should begin within three months. In Anori another American company has done some prospecting work with a small giant, and has just started work on a 2000-ft. tunnel to gain sufficient dumping space for larger operations. A third company, also American, has commenced operations about eight miles from the above.

On the upper Porce river some Colombians are working the Gabine mine by native methods, and it is reported that they have secured over \$130,000 worth of gold in two years. About two miles below this mine some Americans, leasing the La Clara, under Mr. McGuire, have taken out about \$30,000 in about four months' work. In addition to these companies there are a number of smaller concerns that are operating successfully. Most of the ground on the Cauca, Porce, and Nechi rivers has been located, and persons desiring to get property on these rivers are obliged to deal either with native owners or through middlemen, who add a considerable amount to the original price.

Of late years more attention has been paid to placer deposits and many opportunities to obtain good quartz mines have been overlooked. In my opinion, Colombia offers today exceptional chances, not only in the placer mines, but in quartz mines as well, and the mines can be obtained on a far more favorable basis from the owners than can placer ground. Large amounts of capital are required, and the individual with only a small financial backing is not likely to be able to develop an enterprise to the profitable stage of work.

## Discussion

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment. Insertion of any contribution is determined by its probable interest to the readers of this journal.

### A Treatment Problem

The Editor:

Sir—I wish to bring to your notice the following: I have recently taken up a number of heaps of silver tailing (600,000 tons in all), scattered over the province of Junin, Peru. These are the results of the old *patio* process worked by the Spaniards on Cerro de Pasco and other silver ores for the last three hundred years. They consist of very fine material (80% passing through a 200 mesh), silver content 8 oz.,  $\text{SiO}_2$  80%,  $\text{Al}_2\text{O}_3$  1.7%,  $\text{FeO}$  7.7%, and a fairly large amount of mercury. In order to ascertain the true value of the tailing, I want to obtain information in regard to the cost of extraction of the silver. I should feel very much obliged, therefore, if some of your readers would inform me of the results obtained by the companies in Mexico or elsewhere that are working similar material.

HENRY VOGEL.

Cerro de Pasco, Peru, October 12.

### Cripple Creek History

The Editor:

Sir—In your issue of November 2 you published a letter from me containing a correction of an item in your issue of October 12 regarding the shipment of ore on burros from Cripple Creek in 1892. In the letter as published it appears that I corrected the *Colorado Springs Gazette*, which was not the case at all. As you can see by referring to the original communication, I said that *your correspondent* was in error. The item quoted said nothing whatever about burros.

HORACE F. LUNT.

Colorado Springs, November 6.

[We proffer our apologies both to the *Gazette* and to Mr. Lunt. Our 'correspondent' was another Colorado exchange, which evidently elaborated its quotation from the *Gazette*, with unfortunate results.—EDITOR.]

### Cyanidation of Concentrate

The Editor:

Sir—The article on cyanidation of concentrate by Robert Linton in your issue of October 5 recalls to mind an interesting series of tests I ran on raw concentrate at one of the Tonopah mills. With a sulphur content of 30% perfect extraction was readily obtained by cyanidation at 90°F., but the cyanide consumption was 40 lb. per ton. In testing the resultant solution it was found that KSCN was present in sufficient amount to account for about 80% of the cyanide consumption, and consequently twenty or thirty tests were run with various reagents in the attempt to prevent the formation of KSCN. In repeatedly titrating for thiocyanate I was struck by the remarkable resemblance between the curves representing extraction and the concurrent KSCN titrations. After running a few tests it was possible to determine silver extraction to within a few per cent by merely titrating for KSCN. Furthermore, the sulphur present as thiocyanate was found to correspond almost exactly with the sulphur which had been combined with the silver which had gone into solution, and until the extraction of silver became complete only the sulphur so combined entered the solution as KSCN. By prolonging the test beyond the point where all the silver was extracted, considerable sulphur, combined otherwise than with the silver, came into the solutions, so that knowing the amount of silver in the concentrate, the most economic point to stop the test could be determined merely

by the KSCN titration. In extended experimental work I found nothing which prevented the formation of KSCN and finally concluded that either silver sulphide goes into solution without decomposition, or if decomposed, that the KCN snapped up the liberated sulphur ion before any preventive reagent could perform its beneficent function.

NOEL CUNNINGHAM.

Timmins, Ontario, October 14.

### Valuation of Mines

The Editor:

Sir—The following extracts from a report on a Colorado mine, made by a so-called mining engineer, will interest your readers, I hope.

"I personally called upon the owner several times to have him put a price on this property and at first I thought his figures rather high, but later on I had advise from him that he would take \$10,000 cash for the property, but would not give time nor option.

"I consider this one of the best mines in that district after being cleaned out and developed, as the assays show from \$6.00 a ton and upwards, while the vein shows from \$5,000 to \$30,000 per ton and upwards of \$100,000 per ton at 150 to 200 foot level, this being practically a dry mine and can be worked the year round, having plenty of water on the property for milling purposes and Company has a fine milling cite for milling all the lower grade ore, while the high grade ore and select ore can be treated with the Company's own smelter on the ground which would cost the Company \$1,500 or \$2,000. A fifty ton second-hand milling plant will cost from \$2,000 to \$3,000. I believe the Company has enough ore on the dumps to repay for all the machinery and purchase price for the mine, as the assay shows \$6.16 per ton. The company milling 30 tons per day would mean \$300 per day or upwards of \$9,000 per month, and upwards \$100,000 per year.

"Ten to fifteen per cent will pay expenses. This does not include any of the high grade ore which will be encountered in the mine, which increases the output of the mine to a much larger figure and the Company should pay enormous dividends to holders of stock in this Company. I have examined mines for large corporations all over Alaska, Siberia, Australia, South Africa, all over Mexico, Canada and the United States, and I can truthfully say this is the richest mine I have ever examined. The samples I present to you were taken from this mine, also the assays which are included in this report. I am personally interested in this property and would advise any one wishing to purchase stock to buy now as the Company only wishes to sell enough stock to make its payment on the property and erect a mill if so advised by me, the less stock the Company sells the larger the receipts will be and the larger the dividends will be paid the share holders, as there will be no salaried officers except the Manager, Secretary and Treasurer, who will be at the mine looking after their interest as well as the share holders.

"We will suppose that the Company only takes out two tons of high grade ore in one year as per assay attached, this alone representing upwards of \$150,000 per year. Say ten tons at \$20,000 per ton would represent \$200,000 per year. Say then, 1,000 tons at \$100 per ton would represent \$100,000, so you can readily see what enormous dividends this Company would pay on their small investment."

In any case, the moderation of the owner in only asking \$10,000 for a mine from which \$200,000 could be taken per year in 10 tons of ore is worthy of being put on record, as an object-lesson to prospectors.

ALEX. McLAREN.

Llano, Texas, October 16.

Recent regulations governing the platinum industry of Russia prohibit the export of crude platinum after a date to be fixed by the Minister of Trade and Industry.

## Special Correspondence

### MEXICO

SALE OF THE PALOMA.—EXPANSION AT MEZQUITAL.—DEVELOPMENT IN JALISCO.

Normal conditions in Mexico, with the present prices for silver and copper, probably would mean a mining boom. As it is, with generally disturbed conditions and an uncertain future, little money is coming into the country for mining or other investments. According to late advices, the most important deal of the year was recently made and involves the transfer of the Naica silver-lead mines in Chihuahua to French interests for a consideration of several million pesos. One report places the price at \$8,000,000. The mines have been owned by the Compañía Minera de Naica, and it is said that the Mexican stockholders guarantee the sale of a part of the stock of a new company that the French interests are launching. Some months ago the Peñoles Mining Co., controlled by German capital, purchased the Paloma silver-lead mines in the state of Coahuila for \$1,000,000, and the same company is reported to be negotiating for the Cabrilla mines in the same district at a price of \$2,000,000. The Peñoles is operating the principal mines and the smelter at Mapimi, state of Durango. The United States Smelting, Refining & Mining Co. of Boston, controlling the big Real del Monte y Pachuca mines in the Pachuca district of Hidalgo, is willing to invest extensively if suitable properties can be found, but as yet has not figured in a big transaction. Several properties have been examined by representatives of this company this year. Philadelphia men identified for several years with copper mines in the state of Jalisco recently arranged a working bond on the Mezquital del Oro mines in the state of Zacatecas, the purchase price stipulated being \$200,000. It is expected to take over the properties at that figure. An American company was recently formed to take over and work the San Gregorio mines of the Dwight Furness interests in the Guanajuato district of Guanajuato.

The Mezquital del Oro mines in Zacatecas, now under bond to Philadelphia investors, have been owned by English interests for many years. The present company, the San Carlos Gold Mines, Ltd., organized in 1906, succeeded the Mezquital Gold Mines, Ltd., which in turn was a reorganization of an earlier company. The first English company extensively developed the gold properties, and took out several bonanzas. In the bonanza days great quantities of gold were stolen and marketed in Guadalajara. American engineers estimate the available ore in the old workings at more than 300,000 tons and believe that all of it can be milled at a profit. A 50-stamp mill and cyanide plant at the mines are being overhauled, and milling will be started about December 1. Tests of the ore have shown a high extraction with coarse grinding, and it is expected to handle 200 tons per day in the present mill. The Philadelphia men have organized the Mezquital Mining Co. to operate the properties.

In the state of Jalisco neither revolutionists nor bandits have directly interfered with mining, and most of the principal companies have been operating uninterruptedly. The Amparo Mining Co., of the Etzatlan district, is producing at a rate of \$140,000 per month, one-half of which is profit over operating expenses, and is distributing \$60,000 in dividends quarterly. The Southern Pacific has completed a 9-kilometre extension of its Jalisco line, which will be of much benefit to the majority of the mines of the Hostotipaquillo, and will place it in operation immediately. The El Favor, of the Makeever interests, continue to ship heavily, and the Mololoa, under the same ownership, is paying heavy development expenses from limited shipments. The year has seen extensive development at the Casados mines, which are under option to American and French interests for \$4,500,000, and much high-grade ore has been shipped. The Espada Mines Co., which has under lease the mill built by the Virginia & Mexico Co., is now handling 100 tons

per day and shipping concentrate and bullion regularly. The Cinco Minas Co. is busy with work preliminary to the erection of its proposed 250-ton cyanide plant. A branch from Ameca to the Magistral portion of the Ameca district is to be built by the National Railways of Mexico, and this will mean great activity in that copper district of Jalisco. The smelters are eager for the Ameca district ores and concentrates.

While portions of the state of Mexico have been overrun with bandits for months, operations in the El Oro district of that state have not been interrupted. Threats of a raid were made some weeks ago, and while bands approached to points near El Oro, they did not attempt to enter, probably because plans were made for an energetic defense. So far this year the Dos Estrellas Co. has continued its dividend disbursement of \$500,000 per month. Pachuca and Guanajuato are two other important mining districts that have

EL FAVOR MILL, HOSTOTIPAQUILLO.

not suffered directly from revolutionists or bandits this year. In the state of Guerrero there has been serious interference with mining, many important enterprises having been closed down for months. The companies at Pachuca are reported to be shipping bullion as fast as produced, to lessen the chance of loss in case of an attack.

Up to the first of October the production of the Greene-Cananea company was 34,442,000 lb. of copper, 1,010,836 oz. of silver, and 5126 oz. of gold. The 25c. dividend declared in October placed the company's stock on a \$1 per annum basis. A reduction of the Greene-Cananea capitalization is being discussed. The rebel activity at Nacozari in September, with the cutting of the Nacozari railroad, caused the production of the Moctezuma Copper Co. (Phelps-Dodge) to slump that month to 771,844 lb. of copper. The August production was 3,229,839 pounds.

Heavy cargoes of oil are being shipped from Tampico to the United States by the Doheny interests under a new contract with the Standard Oil, which will run for several years. The Pearson interests are shipping from Tampico to England. These interests recently purchased a tract of land just north of Tampico on which they will build a big refinery. Besides the Doheny and Pearson companies, the other producing concerns of the Tampico district at present are the Topila, a Southern Pacific enterprise; the International, of John Hays Hammond and associates; and the Hidalgo, controlled by Los Angeles men.

## NEW YORK

## ALASKA GOLD MINES.—RESULTS AT BRADEN.—THE GRANBY PROGRAM.

The continually waiting attitude of the New York market, which has prevailed so persistently during the past year and a half or more, was not changed by the recent election. Speculation as to the policy of the new administration, formation of the new cabinet, the governmental position toward trust prosecutions, the banking situation, the money trust investigation, and issues of similar import now form an excuse for the prolonging or continuation of the market's waiting attitude. All kinds of activity have been submerged during the past fortnight while the last campaign broadsides were fired and the actual balloting took place. There have been a few days of market buoyancy and activity on the floor of the New York Stock Exchange, but there has not been wanting some coldly skeptical criticism nor expressions of avowed belief in a lack of genuineness in the movements of leading shares and the amount of activity therein.

Some of the leading copper shares have been making high records, particularly Chino, which is in process of distribution and which is expected very shortly to enter the dividend list. These shares have sold at \$50, which is a new high mark for the stock. The Hayden, Stone-Guggenheim-McNeill-Jackling combination is at the moment making its campaign in Chino and in Alaska Gold Mines. The latter is traded in in Boston and New York 'when issued', and the stock, which is \$5 paid, is selling above \$9. A competent and skillful publicity campaign is being carried on, and distribution is proceeding as fast as the public can be brought into the market. It is stated that some 500 men are now at work upon the Alaska Gold Mines property, particular attention being given to the work preparatory to the installation of the company's 6000-ton mill. The old Perseverance mill is running full capacity, but no attempt is being made to derive any revenue therefrom, the work that is being done consisting of tests to deduce the best method of ore treatment. The magnitude of the work is suggested by the fact that three sawmills are at work cutting the timbers to be used in various parts of the construction work. Chino is now said to be earning at least \$6 per share per year, and is expected to earn \$8 per share, or better, as soon as the final unit of the mill is put into commission. During the last quarter Chino has produced 10,000,000 lb. of copper at a profit of \$1,000,000; when operating at capacity its output will reach 6,000,000 lb. per month, and it will undoubtedly be a leader of the low-cost producers.

In the outside market Braden has been a feature during the past week. Braden's convertible bond issue is selling at 150. This is due to the speculative feature which these bonds possess by reason of the privilege of conversion into stock. The shares are now selling at \$7.50, and prospects are stated to be particularly bright. The ore reserve, estimated at some 23,000,000 tons at the time of the last official report, is now stated to have been more than doubled by reason of recent work at the property, and, beginning with the current month, the first unit of the company's mill will be operating under the Minerals Separation Co., Ltd., process, and a recovery of 85% is expected. Early in the coming year the mill will be handling 3000 tons of ore per day and turning out copper at the rate of 40,000,000 lb. annually.

It is rather interesting to note that, in the face of the success achieved by the Braden people in financing the property through a convertible bond issue, the Granby should have definitely decided against a similar course. After a recent meeting of the directors of the Granby, W. H. Nichols, president of the company, made the following statement: "We have instructed our people at the Hidden Creek property to go ahead with the construction of the plant, which will have a capacity of 2000 tons per day, as rapidly as possible. This plant will be financed out of the earnings of the company, which will mean that divid-

ends will be delayed for a while. We have expended so far about \$500,000, and it is estimated that about \$1,250,000 will be required to complete the plant and equipment. This money we now have on hand, so that a bond issue is unnecessary. Developments at the property are very good. We have developed about 5,000,000 tons of ore ranging from 3½ to 8% copper, the average being about 3%. Providing machinery, etc., can be got together, the plant will be in operation in about a year. While the plant will have a capacity of about 2000 tons per day, it has ample water-power for a much larger mill. The plant itself is so arranged that its capacity can be increased at any time." The determination of the Granby board is something of an exception to the rule which has recently prevailed in matters of mining finance. The success of the various convertible bond issues which have been put out have been very attractive to the larger part of mining promoters controlling properties of sufficient magnitude to warrant a bond issue at all.

There are very few mining deals of importance under way in New York. The negotiations for the Shattuck are at a standstill, though it is understood that the only question involved is one of price—a matter upon which buyers and sellers have had different opinions since the beginning of time. The General Development Co. has taken an option on what is now known as the Bagdad Copper Co., and which was formerly known as the Copper Creek. The terms of the option are not stated, but it is said that somewhere between 4,000,000 and 5,000,000 tons of 2% ore has been developed, and the General Development Co. has agreed to expend a certain amount of money and, if a sufficient quantity of ore can be developed, to take over the property. Some tentative efforts have been made to secure an option on the South Live Oak ground, a property which adjoins the old Live Oak, now a part of the Inspiration Consolidated. The production of the British Columbia Copper Co. is showing a gratifying increase each month, the October output being 1,013,000 lb., which compares with 932,000 lb. in September. It is said that the Copper Mountain properties recently acquired by the British Columbia Copper Co. are developing much better than was expected and that a very considerable addition to the output is anticipated from this source.

The copper-metal market has been a featureless affair during the past fortnight. The metal price has been absolutely pegged and lower bids made by consumers both at home and abroad, it is understood, have been rejected. This is, of course, due to the element of combination, the strength of the aggregation which now controls the copper metal market having been the subject of exhaustive comment. The figures of the Copper Producers' Association, covering refinery production for the month of October, show an increase in the surplus in this country of 13,679,000 lb. Against this 'bear' card, one of the copper producers played the consumption of ammunition in the Balkan war, estimating that the ammunition consumed by the Bulgarian army is 155,000,000 rounds of small-arms ammunition per day of fighting; the consumption by the Turks in small-arms ammunition, 260,750,000 rounds. A full five days of fighting is figured to consume 1,303,750,000 rounds of small-arms ammunition, and this is figured to take up, counting in the ammunition of the field pieces, somewhere in the neighborhood of 20,000,000 lb. of copper.

The Hedley Gold Mining Co. is, like some of the copper companies, in line for increased dividends, and has recently increased also its property holdings by the acquisition of five mining claims, upon which diamond-drills have been at work for the past three months. Payment made for the new properties was \$150,000 in cash. Nevada Consolidated and Calumet & Arizona are both expected to increase dividend disbursements when their next meetings are held. New York friends of Walter Harvey Weed are taking a great deal of interest in the new Butte & Zenith City Mining Co., which, as its name indicates, is an organization consisting of Butte and Duluth people who are developing a large area in the old Bluebird district near Butte.

Mr. Weed finds great similarity in the geological formation of the Butte & Zenith City property to that of Butte hill. Old mining men in Butte have always been skeptical about ore being found in this part of the district, and if developments are satisfactory it will prove a triumph for Mr. Weed.

### LONDON

#### CYANIDING AT KOLAR.—RESULTS AT HUTTI.—THE SHEBA MINE.

The mine managers in the Kolar district of India have not had much reason to call the cyanide process to their aid, because the ore is free-milling and from 80 to 90% of the gold content is extracted by amalgamation. The tailing of 15 to 20-dwt. ore contains only 1 to 2 dwt. gold. Nevertheless, the mines all have a cyanide plant and thereby the output and profit are slightly increased. There is some intention now of extending the plant by sliming the tailing and subsequently filtering, following the lead of the Butters plant at Champion Reef. The question of re-treating the vast accumulation of tailing is also under consideration. Probably there is ten million tons of tailing, and much of it will be of higher grade than that now produced, so that the scheme looks decidedly attractive.

While writing of India, it is opportune to record the improvement in the fortunes of the Hutti gold mines in Hyderabad. This mine was introduced in England in 1901 and was floated as a subsidiary of the Hyderabad Deccan company. Milling commenced in March 1903 and dividends were paid from 1903. During the nine months ended June 30, 17,485 tons of ore was milled, and gold worth £46,386 recovered. The profit was £12,417, out of which £7195 has been written off for depreciation, £712 paid as tax, and £3480 distributed as dividend, being at the rate of 5%. Since the closing of the accounts, £4000 has been spent on winding engine, boilers, and steel head-gear for the new main shaft. A Butters filter-plant is being provided for the treatment of slime. The developments at the mine have been eminently satisfactory recently. The high-grade ore discovered on the 1840 and 1940-ft. levels has been proved on the 2040-ft. level, where the lode varies from 2 ft. 6 in. to 5 ft. in width and from 10 to 20 dwt. in content. A winze sunk from the 2040-ft. level is in ore of the same quality. The reserve of ore is estimated at 20,000 tons, averaging 15 dwt., and in addition there is a large quantity of ore of lower grade. The outlook is most encouraging and a renewal of former prosperity seems certain.

The Rand bulks so largely in the Transvaal output of gold that the 'outside' districts are occasionally forgotten. Barberton and Lydenburg were goldfields before the Witwatersrand was discovered. One of the oldest mines is the Sheba, which had a run of prosperity in the nineties, and after 12 years of disappointment has once more won a position on the dividend list. The company was originally formed in 1884 and dividends were paid during the year 1891 to 1898. In 1904 the company was reconstructed. Three years ago it was decided to alter the method of working the properties, and instead of drawing ore from a great number of mines, attention was concentrated on two or three. The results were gratifying, for development disclosed large orebodies, parts of which were of high content. A year ago the nominal capital was reduced by changing the denomination of the shares from £1 to 5s., and now stands at £269,738. During the year ended June 30, 68,865 tons of ore was raised, averaging 12¼ dwt. per ton, chiefly from the Zwartkopje mine. An average of 65 stamps (out of 120) were in operation, and the yield was 34,980 oz. During the previous year, 49,455 tons yielded 24,016 oz. The income from the sale of gold was £148,074. The cost at the mine was £92,442, and London and other charges £4400. The sum of £3804 was written off for depreciation and mine development, and £4632 was paid as taxes. The dividends, at the rate of 15%, absorbed £40,460. During the year 7603 ft. of development work was done, and the ore reserve increased by 22,750 tons to 127,000 tons on June 30. The control is with Lewis & Marks.

One of the steadiest of dividend payers is to be found in the Lydenburg district, namely, Glynn's. The mine, which is on the Sabie river, was opened-up in 1895. Milling commenced in 1897 with 10 stamps, and profits have been made continuously. The plant now consists of 20 stamps and 1 tube-mill. The control is with the Central Mining group. During the year ended July 31, 37,325 tons of ore was mined, estimated to contain 11⅔ dwt. gold per ton. By amalgamation 6983 oz. was recovered, and by cyanide 13,856 oz., the total being 20,839 oz., or 11¼ oz. per ton. The revenue was £87,362, or 47s. 2d. per ton, and the working cost was £42,643, or 23s. per ton. As compared with the previous year, the tonnage was 3455 greater, the yield per ton 1 dwt. less, and the total yield £622 greater. In addition to the working profit, there were sundry items of revenue totalling £2714. The sum of £4557 was allocated to taxes, and £42,500 was distributed as dividend, being at the rate of 25%, the same as during the last six years. The developments during the past year have disclosed 33,245 tons of ore, of the same average grade as that mined, and on July 31 the total reserve was 69,200 tons.

### JOPLIN, MISSOURI

#### ORE MARKET STRONG.—TRANSPORTATION FACILITIES AT NOWATA.—DEEP LEAD ORE AT JOPLIN.

With only a few more weeks to be included in the total of zinc and lead ores for 1912, it is safe to predict that this year's aggregate production will establish a new record. The output of zincblende early in November was 220,000 tons for the year and the aggregate valuation was \$11,950,000. The combined valuation of both zinc and lead ores was \$14,500,000. The largest aggregate valuation in the history of the district was in 1907, when the \$15,000,000 mark was passed. This year will see a valuation in excess of \$17,500,000, and possibly the \$18,000,000 mark will be passed. Next in importance to the production of zincblende is galena, the output now being 45,000 tons valued at \$2,175,000. Calamine does not figure conspicuously in the local production, the output being only 20,000,000 lb. for the year, valued at \$370,000. Already the aggregate valuation of the ores is in excess of the total valuation for last year, which was \$13,055,512. The price of zincblende continues firm, although a slight decline is noted in the past few weeks. The price is now \$52 to \$57 per ton, assay basis of 60% metallic zinc, while choice grades bring as high as \$60. Lead ore brings \$62. Calamine brings \$30 to \$32, basis of 40% metallic zinc, choicer lots bringing \$37.

The Nowata Mining Co., operating at Duenweg, Missouri, has made several innovations in mining in this district, the latest being the construction of a narrow-gauge track, leading from its north ground to its mill, a distance of a half mile, over which a 7-ton locomotive runs, making a round trip every half hour and drawing five 2½-ton ore cars. These are filled from a hopper at the north shaft, are carried to the base of an inclined tramway at the mill, and then hoisted to the ore-bin, the dumping process being accomplished with a projecting wheel which rides an elevated rail and tips the forward end of the car to the front. Formerly the company dressed the ore from its new north workings in an old mill near the shaft, but the necessity for better milling resulted in the construction of the steam railway, the only one of the kind in the district. The shaft from which this ore is taken is into thin sheet ground at a depth of 215 ft. and was raised from the workings beneath. The description of how this was done, by the use of a cable through a drill-hole, a working platform being attached at the lower end, has previously appeared in the *Mining and Scientific Press*. Suffice it to say that the process was so satisfactory from a money-saving and a time-saving standpoint that the company is now raising its second shaft and will soon have it broken through to the surface. In this the method has been slightly modified. The raise will be brought to within 4 ft. of the upper crust of the hard limestone, which occurs immediately beneath the stratum of residual soil. A shaft will penetrate through the residual

soil to the limestone formation. The intervening limestone will then be shot out with one round of shots. In the first shaft the upper part of the shaft was shot down at one blast, no shaft from the surface having been sunk to the limestone. The result was that a large cave was torn in the surface, and the filling of this added expense to the undertaking.

On the G. L. Sansom land, at Belville, northwest of Joplin, new development by three companies has resulted in the opening of some disseminated ore-bearing ground at a depth of 120 ft., and one company, known as the Capitalista Development Co., has driven a number of drifts and found conditions so encouraging that a concentration plant of 150 tons capacity per day has been erected and is now nearing completion. The discovery of an unusually deep body of galena ore on the land of the Granby Mining & Smelting Co. at Joplin is attracting attention. At the Monitor mine, where operations were conducted in disseminated zinc ore at a depth of 140 ft. for many years, the shaft was sunk deeper to develop a deeper body of blende found in drilling on the lease. At a depth of 171 ft., which is shallower than the depth of the deep zinc ore indicated in drilling, rich galena was found, and driving has been started at this level. The formation is proving to be unusually extensive and is much deeper than any lead ore previously mined on the tract.

### FAIRBANKS, ALASKA

WORK ON FAIRBANKS CREEK.—DEVELOPMENT IN DISTRICT.  
—MANY NEW MILLS.

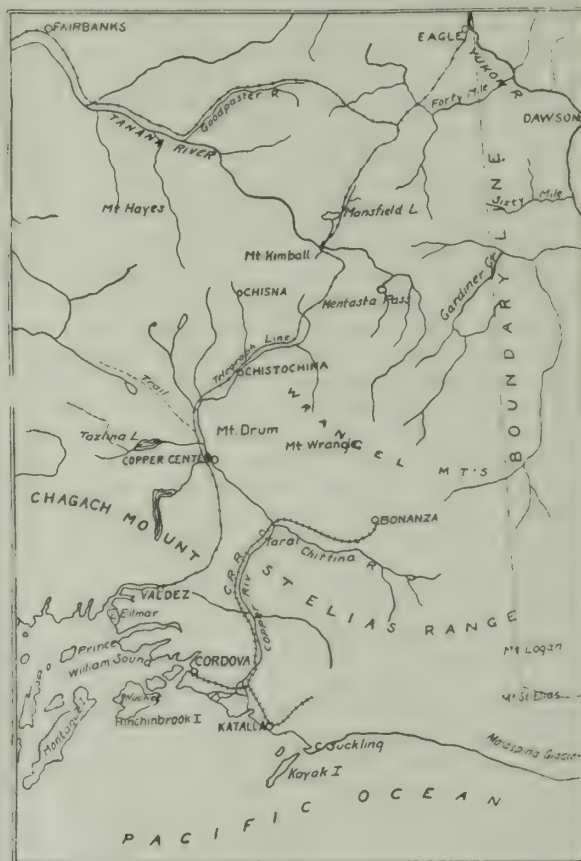

On the divide between Wolf and Fairbanks creek, Furstenu and McCarty are rapidly developing the Pennsylvania quartz claim. A Little Giant mill has been erected on Fairbanks creek and started crushing steadily the first of the month. The mill will also be used as a customs mill in case ore cannot be supplied steadily from the mine. As this mill is the first one brought into the district its performance is being watched with interest. Owing to its light weight and small power consumption as compared to its capacity, a satisfactory run this winter would make it a very popular mill here. A Pierce amalgamator and Monarch table are part of the equipment.

At the head of Fairbanks creek, two outfits are working on the Angus McDougald properties. Mr. McDougald and two men are opening up the Pioneer claim and have a large amount of good ore blocked out. Alois Friedrichs and partner have a lease on the Iron Mask and are sinking at present. After having their claims surveyed, Cook Bros. are preparing to run an adit on the rich vein discovered recently. Several tons of rich ore have been already sacked and it is thought that the winters' work will provide enough ore so that a mill may be ordered in the spring. So far, most of the work on this vein has been done in tracing it on the surface, 1700 ft. of vein being now uncovered. The width varies from 6 in. to 2 ft. A sample taken from the ore sacked assayed \$860 per ton. M. A. Schaffer has a very promising prospect on Fairbanks creek on which he is now working. Coarse gold can be seen in the ore and the owners feel confident of a bright future for their property.

One of the most talked of properties and the cause of a recent stampede to Fairbanks creek, is the Crites & Feldman group of claims opposite 8 Above creek claim. The vein has been traced for 3000 ft. and has a width of 6 in. to 2 ft. Large pieces of ore sprinkled with coarse gold have been taken out of the prospect holes. An adit has just been started, that being the means of development decided upon by the owners. An adjoining claim, belonging to Hannibal Hoover and 'Coal Oil Johnny,' has been bonded recently by George Wheeler for \$100,000. The Kansas Girl, another claim the vein is supposed to cross, was bonded to the same people for \$10,900. This latter claim is owned by Cook Brothers.

A quiet stampede has been on for several days to that part of Fairbanks creek lying between Coffee Dome and the rich claims found up the creek. All open ground is

being staked, more staking than digging being carried on. As all this ground lies opposite some of the richest placer claims on Fairbanks creek, there is good ground for the excitement. The promiscuous staking without discoveries is, however, much to be deplored, as many lawsuits over conflicting claims will result if anything is found. The Alaska Exploration dredge is still working on 8 Above, having turned around and started to make another cut down the pay-channel. With the expectation of doing considerable development work this winter, Gordon and Sterling, owners of the Rainbow on Skoogy gulch, are erecting a large messhouse and installing a double-cylinder

PART OF ALASKA.

hoist. If further developments show the same grade and width of ore, a mill larger than those installed at other properties this year will be put in next year.

Several rich stringers are being prospected by Kinney and Comstock at the head of Fox gulch. While no workable vein has yet been found, the coarse gold in the channel below and richness of the stringers are incentives to active prospect work. A promising vein 2 ft. wide was cut by Kinney and Comstock on the Sunnyside No. 2 recently while the assessment work was being done. While low-grade where cut, the character of the ore will lead to further prospecting. The claim is owned by L. M. Drury. While the customs mills at Chena and Fairbanks will probably be idle this winter on account of high transportation costs, a summary of the properties shows that there will be ten privately owned mills crushing this winter where there was but one last winter. These include the Hudson, Spalding, McGillvray & Fisher, Newsboy, Tolovana, Rhoads-Hall, Burns & McIlroy, Willis & Larson, Horton & Solomon, and the Furstenu & McCarty mill. At least nine of these should crush steadily through the winter and make the quartz output for the year a considerable item. Anderson & Johnson, employing 50 men on 14 Below Cleary, have shut down for the winter, after handling 125,000 sq. ft. of bedrock. It is estimated that three seasons' work remains, and probably next summer 70 men will be employed at the three shafts.

## General Mining News

### ALASKA

#### FAIRBANKS

Around Cleary creek everybody is busy, and the noise of stamp-mills is now constant. On the Pioneer claim on Chatham a mill is being erected. The Tolovana, Rhoads-Hall, and Little Giant mills are working continuously, while the Burns & Serafford mill has been crushing custom ore. In the west end of the 215-ft. level of the Newsboy mine, good quartz has been opened again, after passing through a mass of antimony ore. The mill should be in operation now. After crushing 42½ hours with stamps weighing 250 lb. each, the Spalding claim, on Dome creek, yielded gold worth \$2250, making a total of \$8000 cleaned up during the past summer. A Joshua Hendy 2-stamp mill will be erected on creek claim No. 9 Above, where there is plenty of water throughout the year.

#### NOME

The estimated gold output from the Nome district for the season to November 1 is \$3,500,000. Dredges are expected to operate until early in December. Hodgson & Shaw, representing an English syndicate in Nome, have acquired several valuable properties around Little creek. The property of P. D. Winter was bought for \$125,000. In the spring a large dredge to cost \$200,000 will be built. On October 24 a heavy storm did considerable damage to coastal shipping, and the schooner *Silver Wave*, loading tin ore at Cape York, was wrecked, and ore worth \$20,000 was lost.

Telegraph advice from Nome states that a rich discovery has been made near that centre in the old channel opposite No. 3 Anvil creek. The gravel is 8 ft. deep and averages 25c. gold per pan.

### ARIZONA

#### COCHISE COUNTY

The October output of the Calumet & Arizona smelter was 4,404,000 lb. of copper, against 4,462,000 lb. in September, the total for the year to date being 44,440,000 pounds.

The Bisbee Extension mine and surface equipment has been sold by the sheriff to M. F. Dieus, of Douglas, for \$1100, as he had recently obtained a judgment against the company. The property is situated a few miles beyond the Divide, and work ceased about a year ago. Shipments from claims in the Ash Canyon district are to be made to the El Paso smelter this month. Work has been of an intermittent character at this centre of late years.

#### GILA COUNTY

The October output of the Miami mine was 2,879,750 lb. of copper, against 3,048,750 lb. in September. The Old Dominion output was 2,523,000 lb., an increase of 300,000 lb. over that of September.

#### GRAHAM COUNTY

During October the mines and smelters controlled by Phelps, Dodge & Co. produced 13,165,070 lb. of copper, individual outputs being: Copper Queen, 7,257,746 lb.; Montezuma, 3,045,667 lb.; Detroit, 1,934,828 lb.; and custom ores, 926,829 lb. The Shannon production was 1,210,000 lb. of copper, 220 oz. of gold, and 15,600 oz. of silver.

### CALIFORNIA

#### CALAVERAS COUNTY

Settlements on five cars of ore containing 257 tons, shipped by the Calaveras Copper Co. to the Kennett smelter, returned 11.50% copper, the total returns to the company being \$6391. There are several carloads at the smelter awaiting settlement, and it is expected that during November one car per day will be shipped.

#### SIERRA COUNTY

(Special Correspondence.)—The Keystone Mining Co. is arranging to resume milling. Sufficient water is now available. Portions of the recently developed vein are reported to assay \$100 per ton. The adit gives backs of about 1200

ft. Milling has commenced at the Sacred Mount. The Swastika Mining Co. has placed its 10-stamp mill in action. Good ore has been opened, and recent development has proved satisfactory. The International Reducing Co. is sinking on the vein at the Gray Eagle mine, in the Gold Point section. Hoisting equipment was recently installed. The company is operating under an option, with W. S. Fletcher in charge. The discovery of gold in the porphyry formation is reported by the management of the True Blue Extension mine, near Alleghany. The gold was found in the walls of the deposit, and the find has caused much interest. According to advice from Brandy City, the Brandy City Hydraulic Mining Co. has arranged for vigorous work during the winter. It is said a force of 100 men will be employed and mining conducted on a large scale. San Francisco people are largely interested. Considerable snow and rain has fallen in the Sierras during the past week, and an abundance of water for mining and milling is now available in all districts. Prospectors report 4 ft. of snow in the Four Hills and Gold Valley districts. Several mines that have been idle because of low water are again in operation or arranging to resume.

Downieville, November 8.

#### TRINITY COUNTY

Five tons of ore averaging \$900 per ton has been crushed from the Belli mine, near Carrville, which has been taken on bond and lease by J. McMillan, of Nevada. This mine is noted for the return of \$25,000 from two weeks work by Antone Belli.

#### YUBA COUNTY

A pit is being excavated for the construction of a dredge for the Marysville Gold Dredging Co. The dredge will be fitted with buckets having a capacity of 16 cubic feet.

### COLORADO

#### CLEAR CREEK COUNTY

(Special Correspondence.)—Heavy shipments of ore have been started from the Virginia City mine on Lincoln mountain. Stopping is in progress on the sixth level, and a body of smelting ore is showing which is from 18 to 24 in. wide. Returns of \$75 per ton in gold and silver are obtained. Work has been resumed on the Raymond adit on Griffith mountain. Driving has been started on the Paris vein 800 ft. from the portal. The Boston Mines Corporation has enlarged operations at the Bellevue-Hudson mine on Columbia mountain. Driving is under way on the Anamosa vein, and a vein of 700-oz. silver ore is being followed which is from 6 to 10 in. wide. The new mill being erected near the portal of the Hoosac adit, on Fall river, will be completed within 60 days. The structure is completed, and machinery is now being placed in position. Good headway is being made in the construction of the 500-ton mill, which is to be below the dumps of the Newhouse adit. It will be four months before the machinery will be ready to start work. Extensive development will be commenced this month at the holdings of the Waldorf Con. M. Co. at East Argentine. The Wilcox adit is being repaired and the compressor plant is ready to be started.

Georgetown, November 5.

#### GUNNISON COUNTY

The Forest Queen mine has been purchased by J. G. Berryhill, owner of the Ruby Chief group in the Irwin district. The deal also includes the Irwin water rights and other privileges, with the old plant which will be remodeled and improved for use at the two properties to furnish light and power to operate all the surface machinery. A mill and cyanide plant is to be erected. The Keystone basin adit was started last week for the purpose of prospecting the orebodies under the central portion of Mt. Emmons. J. Larson, of Aspen, who has an option on the Star mine on Italian mountain, and owns other claims in the district, proposes to drive a tunnel through the centre peak of the Italian mountains. The Star mine workings will be cut by this tunnel, and generally it is thought the work will be of benefit to the district.

## LAKE COUNTY (LEADVILLE)

The tonnage for the month of October was an increase on that of September, and was probably the heaviest during the year. The Western, Yak, Iron-Silver, Stars Consolidated, Ibex, New Monarch, Castle View, Ethelma, Sugar Loaf, Dinero, and others produced more than the average tonnage, and the total was about 70,000 tons. As the search for zinc carbonate continues throughout the district, more ore is brought to the surface; and where one mine fails to find zinc, either lead or good bodies of iron are found, and as long as this work continues the monthly tonnage will increase. The last fall of snow practically closed the season in the outlying districts, that is, the work being carried on above timber-line by prospectors. In these parts several companies will work through the winter, among them being the Winthrop Gold Mining Co., Anderson, Kankakee, Ella Beeler, Gleason Gulch, and the Mt. Champion company. Car shortage is being felt throughout the Leadville district.

## OURAY COUNTY

During October 63 cars containing 1512 tons of concentrate were shipped from the district, of which the Wanakah contributed 525 tons. The total for the current year is 15,101 tons. The Barstow mill has been shut down for the winter, due to shortage of water. From June to October, inclusive, the mill produced 1259 tons of lead concentrate. About 200 tons of zinc concentrate is stored at the mine.

## SAN MIGUEL COUNTY

The United States Government is suing the Telluride Power company for \$1500, being the amount of damage done to the Newmire ranger station and buildings by the bursting of the middle reservoir of the power company. This happened on September 6, 1909.

## TELLER COUNTY (CRIPPLE CREEK)

The annual meeting of Stratton's Independence, Ltd., was held in London on November 5. During the year the

CONCENTRATOR ROOM AT STRATTON'S INDEPENDENCE.

total production from mine and mill was \$758,977, the latter treating 112,391 tons of dump ore averaging \$3.10 per ton, from which the gross production was \$253,659, at a cost of \$1.27 per ton. 'Mining' the ore in the dump cost \$0.095, and treatment of concentrate \$0.137, making a total of \$1.52 per ton. The net value of the mine production for the year was \$398,465, lessees contributing \$290,525 of this amount. Dividends absorbed \$120,000. Stratton's has now produced a total of \$21,821,562.

On No. 12 level of the Gold Dollar mine the main ore-shoot has been opened 70 ft. south and 150 ft. north with good results. Four machines are working on the level, and several on No. 8, 10, and 11 levels, while lessees have 12 machines in different parts of the mine. Present production from the Mable M. shaft is 40 cars per month. The C. K. & N. mine on Beacon hill sent out 15 cars of ore during October. The Rapp ore-shoot is 400 ft. long and 4 ft. wide. The company is doing development on No. 9 level, and a cross-cut will be driven 830 ft. before the C. K. & N. vein is cut.

## IDAHO

## SHOSHONE COUNTY

A controlling interest in the Marsh mine, near Burke, has been secured by E. J. Carter and V. D. Williamson, of Spokane, by the purchase of a majority of the capital of 1,290,000 shares. The deal was concluded on October 23. E. W. Greenough, who has been in charge, will be retained as general manager. A shaft will be sunk 400 ft. some distance east of the old inclined shaft. A 12-drill air-compressor driven by 150-hp. motor and other machinery was recently installed. The mine is opened nearly 800 ft. below the apex of the vein. Three adits have been used for development, most of the ore shipped so far coming from No. 3. The mill has been treating 75 tons per day, yielding a concentrate containing 55% of lead, 35 oz. of silver, and a small percentage of gold. The production to date has been over \$120,000 net.

## MICHIGAN

## HOUGHTON COUNTY

No. 22 drill-hole at the Mayflower has proved the lode to be 85 ft. wide, all of which is fairly well mineralized. Assays of the sludge from 1024 to 1086 ft. are said to have returned 40 lb. of copper per ton, against 33 lb. and 26 lb. from No. 20 and 17 holes. No. 21 hole has been restarted, and is down 1000 ft. Preparations are being made at the Adventure to start another diamond-drill from the bottom of the prospecting shaft. Trenching on the Kearsarge lode outcrop at the Isle Royale continues; but nothing of value has been found lately. The Isle Royale railroad connections with the Mineral Range will be completed in a few days, when surplus 'rock' will be shipped to the Allouez-Centennial mill, where a stamp has been reserved for this production. Remodeling the Tamarack stamp-mill is well under way. The Pontiac shaft at the Quincy was connected with the Mesnard at a depth of 3000 ft. by means of a drift and raise from the latter shaft, and was considered a good example of accurate surveying work. The following are October returns from the Lake Superior copper mines: Mohawk, 1,482,000 lb. of copper; Quincy, 2,430,000 lb.; Wolverine, 1,002,000 lb.; Calumet & Hecla, 5,583,424 lb.; Osceola, 1,700,225 lb.; Ahmeek, 1,463,475 lb.; Tamarack, 687,050 lb.; Isle Royale, 712,785 lb.; Allouez, 550,310 lb.; Superior, 238,953 lb.; and Centennial, 152,790 pounds.

The commerce through Portage Lake waterway in October was much greater than during the same month of 1911, there being 256 vessels of 364,811 tons register. The total up-tonnage was 239,574 tons, including 167,838 tons of coal, 14,000 bbl. of cement, and 43,641 bbl. of salt; while the down-tonnage of 511,600 tons included 10,581 tons of copper and 15,017 tons of iron ore.

## MONTANA

## MISSOULA COUNTY

The Iron Mask mine, near St. Regis, is a lead-silver property and a great deal of development has been done. An upper adit is in 1200 ft., while a lower adit, intended to cut the orebody at a depth of 1000 ft., is in 1650 ft. Three veins have been cut, and a fair quantity of shipping ore opened. Equipment includes an air-compressor driven by water-power under 129 lb. pressure. A number of Kellogg and Helena men are interested.

## NEVADA

## ESMERALDA COUNTY

The half-yearly report of the Pittsburg Silver Peak company states that gross earnings of the Silver Peak Gold Mining Co. and Mohawk Alpine company were \$402,025, and net \$49,465; while gross earnings of Pittsburg Silver Peak G. M. Co. were \$211,858, and net \$97,278, the total being \$151,596. Assets include cash, \$458,271; bills receivable, \$60,829; supplies, \$55,164; and depreciation account, \$679,830; while liabilities include accounts payable, \$43,373; and profit and loss account, \$1,009,772. Dividend No. 1, paid July 1, 1912, amounted to \$446,997.

Regular ore shipments are being sent to smelters in

Utah from the deep levels of the Grizzly Bear and Clermont mines of the Goldfield Consolidated. A small but fair-grade orebody has been opened above the 250-ft. level of the Nevada Eagle, situated four miles west of the centre of Goldfield, and shipments are being made. A raise from the 400-ft. level has also proved ore at this depth. This greatly extends the producing area of the district, and may lead to further extensive operations at this point.

#### LYON COUNTY

(Special Correspondence.)—The October production of the Nevada-Douglas company was as follows:

Ore from Ludwig mine, dry tons.....	7491
Copper from Ludwig mine, pounds .....	790,099
Average per cent .....	5.27
Ore from Douglas mine, dry tons.....	4785
Copper from Douglas mine, pounds.....	346,625
Average per cent .....	3.62

Ludwig, November 4.

#### NYE COUNTY

During the week ended November 9 production from the Tonopah district was 9144 tons, valued at \$228,850. Sinking has been resumed from No. 13 level at the Belmont, and the winze is 70 ft. below this level, and will be kept lower than the shaft for drainage. The North Star shipped 45 tons from the 850 and 1250-ft. levels on November 5. At the Halifax main shaft a new electric hoist has been erected. It was made by the Wellman-Seaver-Morgan company, and consists of two drums, each 60-in. diam. and 36-in. face, with friction clutch and post brake driven through one reduction of herringbone gear. It is designed to operate in or out of balance, and capable of hauling the following load: skip, 4000 lb.; ore, 8000 lb.; and rope, 3000 lb., at a speed of 750 ft. per minute. The hoist is operated by a 300-hp. Westinghouse motor, and the electric power is so controlled by a magnetic switch that at no time can the hoist be run at a greater than the set speed, power being automatically controlled independently of the hoisting engineer. The drums are each fitted with 2500 ft. of 1½-in. yellow strand steel rope.

#### STOREY COUNTY

At the Consolidated Virginia the east cross-cut on the 2300-ft. level is out 162 ft., and 10 mine-cars of ore worth \$8.25 per ton were saved during the week ended November 9. The vein is strong and regular, and has 3 ft. of quartz on the hanging wall. On the 2500-ft. level of the Sierra Nevada the northeast drift, which has been crossing the fault met with two weeks ago, is in vein formation. The Mexican mill treated 521 tons averaging \$28.54 per ton, with 93% extraction. Work has been started at the Keyes and Monte Cristo properties recently acquired. The Ophir cyanide plant is working well. Crown Point shipped 110 tons to the Yellow Jacket mill. At the C. & C. pumping shaft the usual pumping and repairs were done, while at Ward shaft all pumps have been removed from the 2475-ft. station. Tanks, discharge, and suction pipes are now being dismantled.

#### WHITE PINE COUNTY

There was milled at the McGill plant during the quarter ended September 30, 797,794 tons of Nevada Consolidated ore averaging 1.74% copper, of which 737,065 tons was from the pits and 60,729 from the Veteran mine, which yielded 18,405,467 lb. of copper. Earnings from the mine, etc., were \$1,816,117, and dividend No. 12 absorbed \$749,784, leaving a surplus for the term of \$1,066,333. Depreciation of Steptoe plant and ore extinguishment totaled \$268,197, leaving net credit of \$798,135. In the assets and liability statement, metals on hand and in transit are worth \$3,798,036, and cash \$1,303,191; while undivided profits are placed at \$3,442,708. Soon after the end of September a strike of miners started, but everything is working nearly full time at the present time. Deep drilling to determine the existence of additional ore at the Eureka pit was begun in September, but work was hampered by the strike referred to.

The Giroux Consolidated mined 85,758 tons of ore dur-

ing, the third quarter of the year, valued at \$414,818. Mining, freight, and treatment cost \$414,728. The Giroux shaft and workings partly filled with water on account of the strike, and unwatering has not been commenced yet.

In an explosion at the Nevada Consolidated company's mine at Copper Flat last July, eight Austrian miners were killed. The Consul General from Austria-Hungary, at San Francisco, appeared through local attorneys at Reno on November 13, as plaintiff in eight suits for a total of \$310,000 against the company. The suit involves seven claims

COPPER FLAT, NEVADA CONSOLIDATED MINES.

of \$40,000 each, and one of \$30,000. The action is taken upon an order issued by the Royal District Court of Austria, which appointed the Consul as administrator for the estates of the deceased men.

#### NEW MEXICO

##### McKINLEY COUNTY

(Special Correspondence.)—Reese H. Beddow has been appointed State Mining Inspector, this being the first appointment to this position. He is compiling a set of mine regulations and is assisted by J. W. Stonehouse.

Gallup, November 8.

##### SOCORRO COUNTY

The Ozark Smelting & Mining Co., owned by the Sherwin-Williams Paint Co., of Cleveland, Ohio, is erecting a 200-ton concentrating plant, to cost \$250,000, at the Ozark group of lead-zinc mines at Kelly. F. L. Preston is the new superintendent. The property has been worked for nearly 35 years, first for silver, then lead, and now for zinc, producing both carbonates and sulphides. The former is shipped, and the latter concentrated. At the present time the Tri-Bullion, McDonald Leasing, and Ozark companies are shipping about 25 cars of zinc and lead ore weekly. At the Nit shaft of the Tri-Bullion a large deposit of copper ore has been opened, and the Ozark company is driving toward the orebody. The old Germania zinc mines at Kelly are idle.

#### UTAH

##### SALT LAKE COUNTY

(Special Correspondence.)—Bingham is beginning to resume a nearly normal aspect, following the breaking of the backbone of the strike, and now the operators are counting the cost. The actual expense has been slight compared with the loss of profits, but the operators generally have been willing to make this sacrifice (which, after all, amounts to deferring rather than losing profits) in order to deal this blow to the Western Federation of Miners. There is no question now as to the complete failure of the strike. As to loss of profits by the Utah Copper Co., the largest producer, figures on output recently released indicate that the loss of profit is not far from \$1,250,000, without taking into account actual expenses. The management of the company, however, considers this cheap when compared with the ultimate cost of a victory by the Western Federation. In the quarterly report D. C. Jackling reviews the strike. He says the underground miners were the cause of the trouble, which he considers over. No at-

tempt has been made to resume underground operations at the mine; in fact, they were nearly ready to permanently discontinue underground mining when the strike occurred. The millmen and Bingham & Garfield railroad employees will receive an increase in wages amounting to a maximum of 25c. per day; but this has been done without recognizing the union or the existence of a strike among miners. The revised scale was effective on November 1, and is to apply so long as copper remains at or above 17c. per pound.

Ohio Copper is another company which is steadily increasing its production. According to A. Frank, general manager, the mill is now treating an average of 2000 tons of ore per day. It is expected to increase this amount by not less than 50% in the near future. The annual report of the Utah Apex company, of Bingham, contains some interesting features, not the least of which is the description of the Parvenu orebody. This is stated to have a width in one place of 200 ft., and to be the largest deposit of lead ore in Bingham. E. P. Jennings, consulting engineer, estimates ore reserves at approximately 100,000 tons.

Salt Lake, November 10.

In its third quarterly statement for the current year, Utah Copper Co. reports that the mills treated 1,581,527 tons of ore, averaging 1.41% of copper, which yielded 29,966,920 lb. of copper, at a cost of 7.707c. per pound. The Magna plant treated 62% and the Arthur 38% of the tonnage. Profit from ore treatment was \$2,539,584, and dividends were paid amounting to \$1,182,412, while the net surplus for the quarter was \$1,744,057. Overburden totaling 1,408,133 cu. yd. was removed. Practically all construction work at the mills is finished. Owing to the acquisition of hydro-electric plants in Utah and Idaho, extension of the Magna steam-power plant is unnecessary. Between September 18 and October 9, operations were interfered with by the miners' strike; but at the present time work is assuming a normal stage.

#### SUMMIT COUNTY

During the quarter ended September 30, the Daly-Judge mine produced 12,791 tons of concentrating and 1224 tons of shipping ore. Lead concentrate amounting to 2247 tons, and 1502 tons of zinc concentrate was sold. The average monthly earnings were \$27,903, and the cash balance was \$540,691. The quarter's net earnings were \$83,710, against dividend requirements of \$45,000. Monthly development covers 1500 ft. on levels below 500 ft. Ore shipments from the district during the week ended November 9 weeks were 1155 tons, and for October a total of 7443 tons, of which the Union Pacific carried 5416 and Denver & Rio Grande 2027 tons.

#### TOOELE COUNTY

At the Consolidated Mercur a little prospecting is being carried on, but so far it has resulted in nothing of importance. The manager, G. H. Dern, states that the mill will work until after the beginning of next year.

### WASHINGTON

#### STEVENS COUNTY

Spokane people have been largely instrumental in developing the copper-silver veins of the Chewelah district. At the United Copper mine, the largest producer, one vein has been opened by an adit to a depth of 500 ft., and driving has proved an ore shoot about 1400 ft. long. Several winzes have been sunk 150 ft. below this adit, with favorable results. A lower adit, which is being driven from near the mill, will give 600 ft. extra depth. The Copper King, north of the United Copper, is working on the same vein to a depth of 400 ft., and a large quantity of ore is ready to mine, as soon as the lower adit is connected. The upper adit, now in 700 ft., is being extended to cut the veins. The Aurora group lies north of the Copper King, and is being developed by a drift from the 400-ft. level of the latter mine. The June-Echo has shipped two cars of ore averaging 4% copper and 20 oz. silver. Other properties attracting attention are the Imperial, Copper Cliff, and Liberty.

### AUSTRALIA

#### NEW SOUTH WALES

The Great Cobar mine in September produced 551 tons of copper, 2502 oz. of gold, and 12,712 oz. of silver. A bakery was established by the company some time ago, and lately an abattoir was opened, resulting in employees getting cheaper supplies. The Broken Hill Proprietary concentrated 20,195 tons of sulphide ore, and reground 14,535 tons of dump tailing, producing 4964 tons of lead concentrate. The flotation plant yielded 6200 tons of concentrate, assaying 46.14% of zinc. During the half-year ended July 31, the Y. Water Tin Co., 463 miles north of Sydney, sluiced 333,000 cu. yd. of gravel yielding 196 tons of black tin, or 1.3 lb. per cubic yard. The record shows 105.3 cu. yd. sluiced per working hour, and 12.6 cu. yd. of water used per cubic yard sluiced. Profit amounted to \$69,000, and dividends \$38,000. The Sydney mint received 40,462 fine ounces of gold for coinage, and for the nine months of the year, 432,517 fine ounces.

#### QUEENSLAND

During August the mills and cyanide plants at Charters Towers produced gold valued at \$194,500; silver, \$800; lead, \$900; copper, \$400; tin, \$6800; and alluvial gold, \$200. The mills crushed 11,964 tons of ore, and cyanide plants treated 12,538 tons of tailing. In September the Brilliant Extended treated 2740 tons, yielding \$29,000, with a profit of \$5300; Brilliant Deeps, 872 tons, yielding \$28,000; Mills United, 1562 tons, \$17,000; and New Brilliant Freeholds, 1456 tons, yielding \$17,500. A good deal of development is being done in the 30 mines of the field.

In September the Mt. Morgan smelters handled 27,720 tons of ore, producing 818 tons of copper and 8959 oz. of gold. Mt. Elliot smelter yielded 625 tons of copper, 1065 oz. of gold, and 1187 oz. of silver from 5848 tons of ore. During the year ended May 31, the Scottish Gympie, at Gympie, crushed 85,100 tons averaging \$5.50 per ton, the profit being \$81,000 and \$61,000 paid in dividends. A cyanide plant is to be erected to treat the tailing. Graphite has been a trouble on this field.

#### VICTORIA

The Melbourne mint has received 465,949 fine ounces of gold this year for coinage. The State Government has a coal mine at Wonthaggi, about 60 miles from Melbourne, and despite labor troubles and much criticism, produced 454,121 tons of mixed coal during the year ended June 30, and over 1,000,000 tons since November 1909. The mine is now capable of producing 3000 tons per day. Systematic boring over 5100 acres proved 20,000,000 tons of coal, allowing 20% for loss in mining. During the year ended June 30, the Central Red, White & Blue company, at Bendigo, crushed 15,471 tons of ore at the 20-stamp mill, details of which were given in the *Mining and Scientific Press* of August 17. The proceeds of gold from amalgamation and sale of pyrite was \$172,000, and \$94,000 was paid in dividends. Mining and milling costs totaled \$3.12 per ton. The mine is in splendid condition.

#### TASMANIA

The Mt. Lyell company is having its share of trouble lately, with labor differences, a heavy fall of ground and fire in the North Lyell mine in which many men were killed. During September 26,468 tons of ore was smelted, yielding 556 tons of copper, 743 oz. of gold, and 36,259 oz. of silver. The Briseis company removed 110,000 cu. yd. of overburden and drift yielding 45 tons of black tin; also dredged 127,000 cu. yd. of gravel in Victoria, yielding \$1200 in gold. The Pioneer company, during the six months ended June 30, sluiced 667,300 cu. yd., yielding 475 tons of black tin at a cost of 9.94c. per cubic yard. Since 1900, 4,979,600 cu. yd. has been sluiced. Reserves are estimated at 5,440,600 cu. yd., containing 0.985 lb. of tin per yard.

### CANADA

#### BRITISH COLUMBIA

The British Columbia Copper Co. produced 1,013,000 lb. of copper during October. The properties in the Copper

Mountain district, on which the company has taken options, are opening in a satisfactory manner. The Queen Victoria mine at Beasley, near Nelson, one of the best known properties in Kootenai, has been sold to the British Columbia Copper Co. About 40,000 tons of low-grade gold-copper ore has been opened at the property, which is equipped with an aerial tramway of 60-ton capacity per eight hours, conveying ore from the mine to the bins at the railroad. The mine is fairly well equipped and is the third property secured by the company. Numerous transfers of mining properties have recently been recorded at Nelson, 16 claims or interests in same having been sold in various districts.

The net earnings of Granby Consolidated during October were \$145,000, against \$181,000 in September. During the week ended November 9 the smelter at Grand Forks treated 24,115 tons of ore, making a total of 1,072,554 tons for the year to date. Blister copper sent out during the week was 435,000 lb., and a total for the year of 10,290,500 pounds.

#### COBALT

(Special Correspondence.)—The slump in La Rose has been checked by the announcement of the discovery of a 6-in. vein of high-grade ore on the 180-ft. level of the Lawson property. On La Rose proper, a shaft is being sunk to the 500-ft. level on the fault vein picked up in cross-cutting on the 380-ft. level in the hope of finding improvement at depth.

Cobalt, November 9.

During the week ended November 2 five mines shipped 269 tons of ore, and four sent out 154,029 oz. of bullion, making a total of 18,579 tons for the year to date.

The Nipissing company has started regular operation of the tramway from the mill to Meyer shaft. There are 19 buckets on the line, each holding 500 lb. of ore, traveling over Cobalt Lake and the town. The Temiskaming & Hudson Bay company has declared dividend No. 43, amounting to \$23,283, making a total of \$1,684,137 to date.

#### PORCUPINE

The Hollinger company has issued a report covering recent work at the mine and mill. Since January 1, 1912, underground development has been satisfactory, and to October 5 total work shows the following results:

100-ft. level:	Length, ft.	Av. Width, ft.	Av. Value.
Vein			
No. 1 .....	1000	3.0	\$31.54
No. 2 .....	665	5.2	12.50
No. 3 .....	136	4.4	5.60
No. 4 .....	485	8.2	12.91
No. 8 .....	56	5.2	4.90
No. 37 .....	70	4.6	11.60
No. 38 .....	66	3.8	15.30
200-ft. level:			
Vein			
No. 1 .....	839	6.7	45.74
No. 2 .....	42	6.2	10.60
No. 4 .....	125	5.0	9.20
No. 37 .....	155	4.2	10.80
No. 41 .....	57	4.5	15.10
300-ft level:			
Vein			
No. 1 .....	63	5.7	8.40
No. 2 .....	63	13.0	16.00
No. 37 .....	63	4.0	20.00

The new mill was started on June 15 and was expected to treat 300 tons daily, but stamps have been tested up to 12 tons per stamp per day, and actual results have proved that 40 stamps can crush from 450 to 500 tons daily. At present 97% extraction is being made on ore worth \$30 per ton. During the period under review 26,221 tons, worth \$23.69 per ton, have been treated, made up of 20,444 tons from development averaging \$19.70, and 5777 tons from stopes worth \$37.89 per ton. A surplus of about \$509,000 is the result of operations since July 1. No further heavy expenditures for plant are contemplated, save additional boilers at the power-plant, and blast and cupel furnaces in

the refinery. At the mill, Dorr thickeners are being erected in place of Trent agitators. The company's assets include cash, \$33,496; and bullion on hand, bullion shipped, gold

NO. 1 SHAFT AND TEST MILL AT THE HOLLINGER.

precipitates on hand, gold in mill solution, and gold in slags worth \$255,568.

#### CHILE

The last 350 ft. driven at the Braden mine, in the No. 1 Teniente, averaged 4% of copper, which is much higher than the average contents of the reserves. This development is in an unexplored section of the property, and the adit is now about 1500 ft. from the surface. During October 42,500 tons of ore was treated, averaging 2.8% copper. In the old mill a recovery of 61% was made, while on 46,000 tons treated by the Minerals Separation process the extraction was 75.5 per cent.

#### MEXICO

##### SONORA

Between October 15 and 31, returns furnished by the collector of customs at Agua Prieta show that 197 cars containing 7694 tons of ore valued at \$1,127,500 were exported from this state.

The Yaqui Indians are causing some trouble in this state and have killed several men lately, besides taking away grain, horses, and cattle. Escorts are being provided for men taking supplies to the mines from Guaymas.

During its past financial year the Boleo Copper Co., of Santa Rosalia, Lower California, produced 14,850,000 lb. of copper, which was shipped to Swansea, England, and France.

#### NEW ZEALAND

The Waihi company has broken the back of the strike, in spite of interference and many miners going to jail, and over 300 men are now at work. Contractors who did not resume, had their contracts canceled. Mining here is all done on contract. At the Thames, the 'Deep Levels tunnel,' at 1000-ft. depth, has been driven 2360 ft. from the main shaft at a cost of \$84,000. This adit is for the purpose of testing and draining the field.

#### PERU

Copper production of Cerro de Pasco for August was over 3,600,000 lb. Nearly all the miners who went to the Tipuani gold rush have left the place, but a few have decided to stay in the country for a while. In *Peru To-Day*, of September, Luis A. Delgado gives a description of the 'Coalfields of Oyon,' which are situated between the Chancay, Cajotambo, and Dos de Mayo provinces. The area is about 55 by 220 kilometres. The coal is semi-bituminous, low in ash and water, and high in fixed carbon, suitable for steamers, or where confined grates are used. The Gasuma Mining Co. uses fine coal in its reverberatory furnaces, and gets a flame 6 metres in length. At present only 280 pertenencias of 40,000 square metres each, have been taken up. Coke is supplied to the smelter at Cerro de Pasco at a low price, it being carried on llamas. The climate is a healthy one, labor is experienced, and the nearest seaport is Huacho, 150 km., from Oyon, of which distance 56 km. is by railroad.

## Personal

Professional men are invited to send news of their engagements and travels. Such news is interesting to friends.

D. C. JACKLING is at Chino.  
B. G. HITE is in Los Angeles.  
J. B. DUMONT is in Salt Lake City.  
M. J. WELCH is in Jerome, Arizona.  
E. P. KENNEDY is in San Francisco.  
W. H. LOVELETT is back from Portugal.  
A. H. NESBIT has returned from Nome.  
JOHN W. FINCH has gone to New York.  
D. W. SHANKS was in El Paso recently.  
HOYT S. GALE was here during the week.  
J. F. NEWSOM has returned from Alaska.  
H. C. HOOVER has returned from the East.  
W. C. OREM is at the Nevada-Douglas mine.  
JOHN E. PELTON is here from Los Angeles.  
JOHN HAWKINS is here from Elks, Nevada.  
COREY C. BRAYTON has returned from Nome.  
F. L. GARRISON is in Mono county, California.  
D. H. STEINMETZ was in San Francisco recently.  
P. D. BURTT has returned from southeastern Alaska.  
R. C. CRANSTON has gone to Brazil on professional work.  
J. E. SPURR and S. H. BALL were in San Francisco Tuesday.

F. W. BRADLEY has been elected president of the Ocean Shore railway.

WALTER CURRIE was in a motor accident last month, but escaped uninjured.

H. M. SPICER is now in London, returning from a seven months trip to India.

W. J. MCGEE, who has been ill at the St. Francis hospital, has returned to Sutter Creek.

ARTHUR L. PEARSE left London on October 26 on a tour of inspection in the south of Spain.

J. B. TYRRELL has returned to Toronto from a five months expedition to the shores of Hudson's Bay.

E. K. SOPER has left Minneapolis for Sierra Majada, Mexico, expecting to be absent six or eight months.

REESE H. BEDDOW has been appointed State Mine Inspector for New Mexico, with headquarters at Gallup.

F. H. PROBERT, who was recently appointed consulting engineer to the Shannon Copper Co., is at Clifton, Arizona.

RALPH H. RAMSDALL, general manager for the Casados Mining Co., was recently attacked by the brother of the Mexican who killed THOMAS D. MURPHY last year, but escaped with only a slight wound.

## Obituary

THOMAS KAVANAUGH died at Phoenix, Arizona, on November 5, 1912. He had been a resident of Arizona for many years and was interested in mining operations in different portions of the state, but principally in and around Globe. He was associated with Philip Wiseman and others in the promotion of the Ray Con. Copper Co. several years ago, and later in the sale of the Inspiration property to its present owners. In addition to his mining interests he had business and real estate holdings in Globe, Tucson, Phoenix, and Ray. Having been closely identified with the life of Arizona for so long, he leaves a large circle of acquaintances. He made his start as a practical miner, and by his energy and determination, coupled with splendid mining judgment and high moral principles, not only won material success, but obtained the respect and esteem of all with whom he came in contact. He was a splendid exponent of the highest type of self-made men.

## Market Reports

### LOCAL METAL PRICES

San Francisco November 14.

Antimony.....	11-11½c	Quicksilver (flask).....	41.50
Electrolytic Copper.....	18-18½c	Tin.....	52-53½c
Pig Lead.....	5.00-5.05c	Spelter.....	8½-8½c
Zinc dust, 1400 lb. casks, per 100 lb., small lots \$9.50-9.75; large \$7.50-8.50			

### METAL PRICES

(By wire from New York.)

NEW YORK, November 14.—The copper market is firmer owing to the demands for home trade and increased sales in Europe where buyers are all poorly covered. The lead market is quiet and inclined to be weak. Spelter remains steady. Average daily prices for the past week, in cents per pound, based on wholesale transactions, standard brands, are given below.

Date.	Electrolytic Copper.	Lead.	Spelter.	Silver, per oz.
Nov. 7.....	17.23	4.70	7.25	62½
" 8.....	17.28	4.68	7.25	62½
" 9.....	17.28	4.68	7.25	62½
" 10.....	Sunday.	No market.

Company Reports

AMALGAMATED ZINC (DE BAVAY'S), LTD.

At Broken Hill there are two large flotation plants which treat the tailing bought from the mining companies. These are known as the Amalgamated Zinc, and Zinc Corporation, respectively, treating 43,000 and 27,000 tons of tailing per month.

The half-yearly report of the former gives the following details:

Treated, tons .....	259,425
Zinc concentrate produced, tons.....	70,496
Metal contents:	
Zinc, per cent.....	49.1
Lead, per cent.....	6.2
Silver, ounces .....	9.3
Lead concentrate produced, tons.....	992
Metal contents:	
Lead, per cent.....	53.2
Zinc, per cent.....	17.0
Silver, ounces .....	35.8
Average price of spelter, per ton.....	\$124.36
Net profit for term.....	475,000
Dividends paid .....	370,000
Dividends paid to date.....	1,120,000
Surplus liquid assets .....	395,000
Carried forward .....	250,000
Reserves .....	120,000

During the period under review \$86,000 was spent on tailing purchased, and \$120,000 on additions to plant, which included another unit to the acid plant, and a 400-kw. low-pressure turbo alternator.

CONSOLIDATED MINING & SMELTING COMPANY OF CANADA, LTD.

This company is mainly a holding corporation, controlling the following mines in British Columbia: Centre Star, Le Roi, St. Eugene, Richmond Eureka, Molly Gibson, Phoenix Amalgamated, No. 1 and No. 7, and the Sullivan group; while it owns and operates a smelter at Trail. During the year ended June 30, 18,549 ft. of development and 20,282 ft. of diamond-drilling was done at the mines mentioned. Generally the condition of the mines is good. During the year Le Roi property was acquired which has added materially to the tonnage of ore and shows a fair profit on operations. Some mines have been purchased and others taken on option. The smelter treated 296,458 tons of ore yielding 26,072,074 lb. of lead, 2,914,181 lb. of copper, 129,789 oz. of gold, and 1,765,992 oz. of silver, valued at \$5,083,078. A good deal of custom lead ore has been sent in during the year. The strike at the coal mines at Crow's Nest Pass affected operating costs, and the cost of electric power is higher than formerly. Compressor plants driven by water-power were built at the Sullivan and Molly Gibson properties. At the smelter the flue has been enlarged, the matte handling plant rebuilt, lead sampling plant altered, and a number of electric traction lines have been laid down to facilitate handling of ores, fluxes, and bullion. The year's work shows a profit of \$310,346, after writing off \$185,120 for depreciation; development of properties under bond, \$43,120; and charging profit and loss account with \$319,549 for development of the company's properties. Purchase and development of new properties cost \$337,018, and the amount due to banks for borrowed capital is \$343,819. The credit on the profit and loss account now stands at \$1,183,635.

ROOIBERG MINERALS DEVELOPMENT CO., LTD.

This company was organized in 1908 and owns 3186 morgen of land in the Rustenberg district, Transvaal. The authorized capital is £180,000 in shares of £1 each, all issued and fully paid. A 10-stamp mill was constructed in 1910 and an additional 10 stamps was added early this

year, as well as equipment for treating the accumulated middling and slime. During the year ended June 30, 1912, the mill treated 20,800 tons, of which 789 tons was accumulated middling and slime and the rest ore. The total amount treated was 20,799, and the yield of concentrate was 884.58 short tons, equal to 789.8 long tons. The average metallic content of the concentrate was 67.89%, and the recovery was 57.97%. The reserve on June 30 of middling and slime to be re-treated was 44,485 tons having an average assay value of 2.51% metallic tin. A Brunton roasting furnace and a magnetic separator have been provided, and by their means the content and quality of the concentrate will be increased. As regards the development done during the year, Edward S. Schoch, the manager, reports that owing to the irregularity of the deposit it is impossible to give a dependable estimate of ore reserve, but he states that disclosures of profitable ore continue to be made. His figure for the ore reserve on June 30 was 21,300 tons, with a recovery value of 4.7% metallic tin. He mentions also that the content per ton treated has been less than during the previous year and that it will probably remain at this lower level, the reason being that the dumps containing high-grade material are approaching exhaustion. The sale of concentrate during the year brought an income of £105,617 and the profit was £33,547. Out of this £27,000 has been distributed as dividend at the rate of 15 per cent.

The Tin Market

The position at the end of October was more favorable than was expected, according to a report by L. Vogelstein & Co., the decrease in visible supply being 2510 tons. United States deliveries were 3850 tons, an increase of 350 tons for the month, and 3650 tons for the year to date. Shipments from the Straits Settlements were 4425 tons during October, while the increase over the first 10 months of last year is 4057 tons. Australian shipments have decreased 220, and Bolivian 1335 tons. Consequently supply has fallen short of demand by about 5600 tons; and the visible has decreased approximately this amount this year. It is estimated that the visible supply will decrease 1000 tons by the end of the current year, so stocks will be at a record low total. During the past four years between January and April, the average decrease in stocks has been 4262 tons. Should the year finish with only 10,000 tons on hand, and the January-April 1913 period be robbed of 4000 tons, tin prices cannot go lower. Requirements for future delivery should be covered in view of these facts.

No new mining enterprises were started in Turkey during 1911. After the declaration of the Turkish constitution there was a great demand for mining properties, and several American companies sent out engineers with a view to acquiring any likely deposits, but no results have been obtained. During the year new concessions were granted by the Government for three chrome mines, two emery mines, one mercury mine, and one silver-lead mine. Thirty or forty claims were also registered. Minerals exported from the province of Smyrna during the year ended March 13, 1912, were as follows:

	Tons.	Value.
Antimony .....	830	\$ 4,382
Chrome .....	13,870	137,313
Copper .....	3	69
Emery .....	21,436	339,546
Iron .....	2	13
Lignite .....	1,602	3,524
Manganese .....	1,400	9,240
Mercury .....	27	25,806
Silver-lead .....	140	4,928
Totals .....	39,310	\$524,821

AN iron mine is to be opened at Chateaubriant, near that French city, by the Compagnie Générale des Mines de Fer de Bretagne, of 18 Rue Lafayette, Nantes.

## Book Reviews

Any of the books noticed in this column are for sale by, or can be procured from, the MINING AND SCIENTIFIC PRESS.

**THE BUSINESS OF MINING.** By Arthur J. Hoskin. 219 pp. Ill., index. J. B. Lippincott Co., 1912. For sale by the *Mining and Scientific Press*. Price \$1.50.

This is a popular exposition of the business side of mining, pointing out in readable form why many mining ventures fail.

**A TEXT-BOOK OF RAND METALLURGICAL PRACTICE.** Vol. II. By C. O. Schmitt. J. P. Lippincott & Co., Philadelphia. 432 pp., index. For sale by the *Mining and Scientific Press*, San Francisco. Price \$6.50.

This second volume of the set is divided into two sections, the first dealing with the design and construction of reduction plants, and the second with the transport of materials. Of the two volumes, the second is distinctly more valuable than the first. There are more specific data, more concrete facts, since the practice on the Rand, and the Rand only, is covered, and there is an absence of the generalities that are really superfluous in such a work as this purports to be. Only thirteen pages are given to an introductory statement, which, however, should not be neglected, as it is full of suggestions that, while they perhaps have not been presented here for the first time, are nevertheless helpful and replete with good sense. More space might have been given to the factors influencing the design of reduction plants; in fact, a book might be written on this subject alone. Judging by the many blunders that are committed in this particular, more enlightenment would be welcome. Much cost data are given throughout, which, being admittedly accurate, enhances the value of the publication many times. The frequent use of good line-cuts to illustrate the text is to be commended. This type of illustration, from an engineering standpoint, is far more valuable than photographs, by reason of the clear idea that is given of construction details. Data on sorting will interest many operators in the United States and Mexico, where the methods employed on the Rand may be applied to some ores with good results. The general subject of ore dressing is discussed so exhaustively that it is doubtful if such complete data have ever before been published elsewhere than in R. H. Richard's treatise. The prevalence of the flat millsite on the Rand has brought about a set of special requirements for ore-bin and building design that find few, if any, counterparts on the American continent, but the designs used are none the less interesting; in fact, many of the structural details could be adopted to good advantage in American mill practice. An extended discussion is given of the vexed question of broken cam shafts, but from the fact that no definite solution of the difficulty is offered, it is evident that the question is still far from settled. Nothing of importance is added to the data already published on heavy or individual stamps. The test made of the Nissen stamps against the heavy stamps in the City Deep mill is mentioned, but the author apparently does not regard the result as marking the end of the 5-stamp unit on the Rand. Data on fine grinding are both interesting and instructive. Flow-sheets are discussed and the result of variations in feed, classification, types of lining, etc., are given in detail. Amalgamating devices and clean-up apparatus employed are, with a few variations, of California origin, and present nothing essentially new. The section devoted to cyaniding is by far the most interesting part of the book. It is on the Rand that sand treatment by leaching has been developed to its greatest possible usefulness, and the subject matter will well repay careful study. The craze in America for sliming everything indiscriminately has subsided to a great extent; the cyanide engineer of today gives due consideration to the economic advantages to be found in double treatment whenever possible. Slime treatment methods are covered exhaustively, construction details as well as metallurgical features being described in full.

The many patented processes that have been tried out with more or less success are described, but no opinions are advanced as to their value. It is pleasing to note the attention that the author has given to the question of power supply. More could have been written on this subject, as there is no question but that with such large-scale operations as exist on the Rand many economies might be achieved through the careful study and attention of a power specialist. A schedule of items as a guide for making estimates is given, and chapters are devoted to construction costs and transport of materials. As a whole this volume is excellent, and beyond its local interest, forms a distinct addition to the literature on milling practice.

## Recent Publications

**MINE FIRES.** By G. S. Rice. Bureau of Mines Technical Paper 24. 51 pp., ill., index. Washington, 1912.

**SUMMARY REPORT OF THE GEOLOGICAL SURVEY BRANCH OF THE DEPARTMENT OF MINES, CANADA, 1911.** By R. W. Brock. 412 pp., maps, index. Ottawa, 1912.

**GEOLOGY OF THE NEW PLYMOUTH SUBDIVISION, TARANAKI DIVISION.** By E. de Courcy Clarke. New Zealand Geological Survey. Bulletin No. 14. 58 pp., index, maps. Wellington, 1912.

**PRODUCTION OF NATURAL GAS IN 1911.** By D. T. Day and B. Hill. Advance chapter from 'Mineral Resources of the United States, 1911.' U. S. Geol. Surv. 58 pp. Washington, 1912.

**FIRST ANNUAL STATISTICAL REPORT OF THE SAN FRANCISCO CHAMBER OF COMMERCE FOR YEAR ENDED DECEMBER 31, 1911.** Prepared by T. C. Friedlander. 94 pp., ill., index. San Francisco, 1912.

**PAPERS ON THE CONSERVATION OF MINERAL RESOURCES.** Reprint from Report of the National Conservation Commission, 1909. U. S. Geol. Surv. Bull. 394. 214 pp., ill., maps, index. Washington, 1909.

**COMPARATIVE STATISTICS OF LEAD, COPPER, SPELTER, TIN, ALUMINUM, NICKEL, QUICKSILVER, AND SILVER FOR 1911.** 107 pp. Metallbank und Metallurgische Gesellschaft, Frankfurt-on-main, Germany, July 1912. Although somewhat late in the year, this annual publication is of much interest and value, and its statistics may be relied on as being accurate. The principal metal mining companies of the world are reviewed in tabulated form.

**UTILIZATION OF PEAT FUEL FOR PRODUCTION OF POWER.** By B. F. Haanel. A record of experiments conducted at the fuel-testing station, Ottawa, 1910-11. 145 pp., ill., tables, plans. Ottawa, Canada, 1912. This is an interesting publication and contains a great deal of valuable information. The fuel-testing station is equipped with a Korting peat gas-producer and engine, an electric generator, switchboard, motors, a chemical laboratory, and accessories. It was erected to test the various kinds of fuel produced in Canada. The theory of producer-gas is described in a practical way, while the description and plans of producers and engines is especially good. The fixed carbon in the peat experimented on was 25.2%, and the calorific value of the dry fuel, 8650 b.t.u. per pound. Tests ran 7 to 30 hours, and the average fuel consumption was 1.68 to 2.2 lb. dry weight per brake-horse-power. Using coal or charecoal the usual consumption is about 1 lb. Tar was a nuisance in these tests, so the producer was altered by Korting Bros., of Hanover, Germany, and 26 tests made, with the following conclusions: The present type of producer-gas plant is reliable; tar is not troublesome; regular cleaning of pipes and engine is necessary; average consumption of dry peat per brake-horse-power is 1.7 lb., with full load; with a load factor of 75% for 3000 hr. work per year, and fuel delivered at \$2 per ton, the fuel costs would be \$8.40 per brake-horse-power-year, including stand-by losses. Sulphate of ammonia and tar can be recovered as by-products.

## Concentrates

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

**NATURAL GAS** produced in 1911 from 10,809 productive wells in Pennsylvania totaled 154,475,376,000 cu. ft.; from 4717 in Ohio, 112,123,029,000 cu. ft.; 4755 in West Virginia, 80,868,645,000 cu. ft.; and 2004 in Kansas, 77,861,143,000 cubic feet.

**LIMESTONE** deposits are practically inexhaustible in the United States. The production of lime in 1911 from 1089 producers was 3,392,915 short tons, valued at \$13,689,054. Pennsylvania had the largest output, of 841,723 tons, worth \$2,688,374.

**ANTIMONY** in an ore generally interferes with subsequent cyanide treatment. Weak cyanide solutions, preliminary caustic soda treatment, and roasting at low temperatures have been suggested and tried. Several plants in Australia have made fair success in tailing treatment. A neutral or slight protective alkalinity is aimed at for best results. If the protective alkali is in excess, antimony sulphide is taken into solution and subsequently deposited on the zinc-shavings as metallic antimony. The addition of lead acetate would throw down a certain amount of sulphide which may be in solution.

**VANADIUM** steel superheater bends made by the American Steel Foundries plant, at Pittsburg, had the following analysis: C, 0.256%; Mn, 0.650; Si, 0.320; S, 0.030, P, 0.030, and Va, 0.200%. Tests showed the elastic limit to be 54,940 lb. per square inch; ultimate strength, 89,320 lb. per square inch; elongation in 2 in., 26%; and reduction in area, 47.8 per cent. Vanadium cast steel racks for a bridge, made by the Pennsylvania Steel Co., gave the following results from three heats: Elastic limit, 55,000 to 59,000 lb. per square inch; tensile strength, 92,000 to 94,000 lb. per square inch; elongation in 2 in., 20%; and reduction of area, 34 to 38.5 per cent.

**PALLADIUM** finds a fairly large use in technology. Circles of astronomical instruments are made of it, and it is also employed in watchmaking. Its most extensive use is probably for certain alloys in dental work. It is also employed for soldering platinum metals. As it is not altered or discolored by exposure to air, it is often used for plating metal ware. The demand for this metal is greater than the supply. In 1911, according to the U. S. Geological Survey, 2390 oz. of palladium was produced, 300 oz. from crude foreign and domestic sands, and the rest from the refining of copper ores and copper bullion. In the same year 1218 oz., of an average value of \$46.22 per oz., was imported into the United States.

**MOTION** necessary to be imparted to the deck of a concentrator of the table type consists of moving it longitudinally of the riffle cleats upon its surface, and toward the concentrate discharge end, from a position of comparative rest, with a gradually accelerated speed to the end of the stroke, reversing the direction quickly with a maximum of speed, which gradually diminishes during the return to the position of comparative rest, at the beginning of the forward stroke. This has the desired effect of agitating and inducing the stratification of the settling material, which is caught in the channels between the riffle cleats and advancing the same at each stroke of the mechanism toward the riffle tips. Here the cross-flowing water gives a final cleaning and removal of gangue as the material approaches and passes the riffle tips. The heavier concentrates, in order of their specific gravities, pass out upon the cleaned ore plane, and are carried forward to the concentrate discharge end of the deck, and the tailing rejected as waste.

## Decisions Relating to Mining

Specially reported for the MINING AND SCIENTIFIC PRESS.

### JOINT MINING VENTURE—ACCOUNTING

Where five persons, including the defendant, associated together in a joint venture to lease mining property in Mexico, which was nominally leased in the name of a third person, and also to take an option to purchase in the name of one of the associates, not a party to this action, and the leased property and proceeds are still in the custody of the nominal lessee the defendant cannot be compelled in equity to account to any of the other associates for their share of the proceeds of the leased property pursuant to the agreement of association, as it nowhere appears that defendant ever came into custody or control of any of the property.

*Bowman v. Furber*, (New York) 137 New York Supplement, 560. October 4, 1912.

### ASSESSMENT WORK—VALUE

Where defendant had almost continuously worked mines in controversy from February 15, 1908, until May 10, 1909, when plaintiffs took possession and dispossessed her, defendants being in possession January 1, 1909, performing work, the claims were not subject to relocation, and work thereafter performed would apply on the work required for 1909. The value of assessment work done on mining claims by hydraulic washing is not determined by the wages of the man holding the nozzle, but by the result accomplished, including the value of the use of the plant comprising the water rights, ditches, pipe-lines, giants, etc.

*Anderson v. Robinson*, (Oregon) 126 Pacific, 988. October 1, 1912.

### TAXATION OF MINING CLAIMS

The constitution of the state of Nevada exempts from taxation patented mining claims on which at least one hundred dollars worth of labor has been expended during the year. The net proceeds of such claims alone are taxed. If at least one hundred dollars has not been expended for labor and improvements, then the claim shall be assessed at not less than five hundred dollars valuation. Held that the language of the Constitution exempting claims on which one hundred dollars had been expended is mandatory and not merely permissive. It was the intention of the legislature to encourage development work upon patented claims by exempting the land from taxation where work was being done, not merely to permit assessors to take that fact into consideration in making assessments.

*Goldfield Consolidated Co. v. State of Nevada et al.* (Supreme Court of Nevada) Oct. 17, 1912. (Not yet reported.)

### PHOSPHATE DEPOSITS—CHARACTER OF LOCATION

Where extensive deposits of calcium phosphate or 'rock phosphate,' which is found in sedimentary beds or deposits in Idaho were located and patented under the placer laws, and a subsequent attempt was made by parties adverse to the patentees to locate the same claims under the lode laws, alleging that the deposits occur "in place" in the mass of the mountains between defining walls of country rock with surface outcroppings, it was held by the Federal court that it could not disturb the original findings, of the Land Department that the deposits were placer in character. While the rulings of the Department have been somewhat inconsistent with respect to the phosphate locations in this section of the country, some of them being patented as placers and some as lodes, still these findings are findings of fact and as such must be treated as properly within the jurisdiction of the Land Department and conclusive.

*Duffield and Jeffs v. San Francisco Chemical Co.* Decision rendered Sept. 3, 1912, by Judge Van Fleet in the U. S. District Court for Idaho. (Net yet reported.)

## Catalogues Received

**HARDINGE CONICAL MILL Co.**, 50 Church street, New York. Catalogue No. 5. 20 pages. Illustrated. 6 by 9 inches.

**POWER SPECIALTY Co.**, 111 Broadway, New York. Catalogue, 'Foster Superheaters.' 32 pages. Illustrated. 6 by 9 inches.

**BROWN HOISTING MACHINERY Co.**, Cleveland, Ohio. Catalogue E, 'Brownhoist Buckets and Tubs.' 56 pages. Illustrated. 6 by 9 inches.

**INGERSOLL-RAND Co.**, 11 Broadway, New York. Catalogue No. 75, 'Water Lifted by Compressed Air.' 72 pages. Illustrated. 6 by 9 inches.

**MILLER SAW-TRIMMER Co.**, Alma, Michigan. Price list, 'Miller Saw-Trimmer and Special Attachments.' 20 pages. Illustrated. 5 by 8 inches.

**THOMPSON BALANCE Co.**, Denver, Colorado. '1912 Catalogue of Balances and Weights of Precision.' 28 pages. Illustrated. 6 by 9 inches.

**E. I. DU PONT DE NEMOURS POWDER Co.**, Wilmington, Delaware. 'Permissible Explosives for Coal Mines.' 18 pages. Illustrated. 6 by 9 inches.

**ISBELL LINING MACHINERY Co.**, 306 Columbia Trust building, Los Angeles, California. Bulletin No. 2, 'Isbell Concentrator.' 12 pages. Illustrated. 8 by 10 inches.

**NORDBERG MANUFACTURING Co.**, Milwaukee, Wisconsin. Bulletins 20 and 21, describing Nordberg 'S. C.' belted type compressors; and the Nordberg 'Uniflow' engine. 7 pages. Illustrated. 8 by 10½ inches.

**INTERNATIONAL CONSTRUCTION Co.**, Orange, New Jersey. Concentration of ores by the International dry concentrator is explained, and 7 pages giving specific gravity of minerals. 28 pages. Illustrated. 3½ by 6 inches.

**ALLS-CHALMERS Co.**, Milwaukee, Wisconsin. Bulletin No. 1526, 'Allis-Chalmers Corliss Engines.' 16 pages. Illustrated. 8 by 10 inches. Also Bulletin No. 1629, 'Hydraulic Turbines,' 20 pages. Illustrated. 8 by 10 inches.

**CHICAGO PNEUMATIC TOOL Co.**, Chicago. Booklet No. 119, 'Operation and Upkeep of Rockford Railway Motor Cars.' 24 pages. Illustrated. 3½ by 6 inches. Also Bulletin No. 118, 'Chicago Giant Rock Drills,' and Bulletin No. 120, 'Instructions for Setting Up and Operating Chicago Giant Rock Drills.' Both 8 pages. Illustrated. 6 by 9 inches.

**LUDLOW-SAYLOR WIRE Co.**, St. Louis, Missouri. Catalogue No. 45, 'The Perfect Double Crimped Wire Cloth.' 77 pages. Illustrated. 8 by 10 inches. This is the best catalogue of its kind that has come to our notice and should be in the hands of every user of wire cloth and screens. Aside from being a credit to the printer, it contains valuable tables, information relating to the mesh, number of wire, and size of openings of screens.

## Commercial Paragraphs

In the front cover advertisement in this journal of October 26 it was stated that the entire power required for the operation of the L. C. TRENT UNIVERSAL CYANIDING MACHINE is 20 hp. per ton of ore treated. This was a typographical error and should have read 0.20 hp.

The **HARDINGE CONICAL MILL Co.** announces the sale of the exclusive rights to manufacture and sell, under their patents, the Hardinge conical mill in Arizona and Sonora. L. D. Ricketts, general manager of the Inspiration Con. Copper Co. and the Cananea Con. Copper Co., is the purchaser.

Ralph A. Gould, formerly chief of the San Francisco Food & Drug Inspection Laboratory of the United States Bureau of Chemistry; Edward E. Free, formerly with the United States Bureau of Soils in field potash investigations; and Charles S. Ash, formerly chemist and

assistant superintendent of the California Wine Association, announce their association under the firm name of **GOULD, FREE & ASH**, Chemical Engineers, with offices in the Monadnock building, San Francisco.

## Largest Direct-Current Generators

Seven vertical water-wheel type electric generators, of the largest capacity ever built for generating direct current, will be installed in the new plant of the Southern Aluminum Co., at Whitney, North Carolina. Each machine will have a rating of 5000 kw., delivering 20,000 amperes at 250 volts, and operating at a speed of 170 r.p.m. Two smaller direct-current generators of the same type, rated 2500 kw. at 300 r.p.m.; two 1250-kva. alternators, having a speed of 514 r.p.m., with two 16-kw. exciters; and all necessary switchboards and controlling devices are also included in the installation. The contract for all the electric apparatus has been placed with the General Electric Co., and the installation will be one of the largest and most modern of its kind in the world.

It is the intention of the Southern Aluminum Co. to have in operation in the course of the next eight months a manufacturing plant that will turn out 25,000 tons of aluminum per year. The company was recently incorporated under the laws of the state of New York with a capitalization of \$8,000,000 and was organized by some of the largest aluminum manufacturing companies of Europe. The enterprise has been financed in France and is closely associated with L'Aluminium Français of Paris. The work at Whitney is in charge of Paul Heroult, an eminent French engineer, who is recognized as an authority on the manufacture of aluminum. Although Mr. Heroult has been directing constructive operations there but a few weeks, remarkable progress has been made, and it is confidently expected that the entire plant will be in readiness for turning out the product of the company by the middle of 1914.

The plant throughout will rank among the largest and most perfectly equipped for the manufacture of aluminum in the United States. Only one other in the country, at Niagara Falls, can compare with it. In the complement of buildings are nine furnace rooms, wherein the aluminum oxide will undergo the various processes incidental to conversion into aluminum. Each of these structures measure 60 by 500 ft., and one electrode factory of similar dimensions is also included in the group. Aluminum, because of its lightness and toughness, find wide application nowadays. Aluminum wire and cable are rapidly coming into extensive use for the transmission of high-tension electric power.

The immense machines, which will supply the electric current for the several operations of this vast industry, will be installed immediately over wheel-pits and directly connected to vertical shafts of S. Morgan Smith turbines by forged flanged couplings. Each 5000-kw. generator will weigh in the neighborhood of 150 tons, measure 22 ft. in diameter, and extend 13 ft. above the floor-level. The entire rotating element of the generators will be supported from an overhead thrust-bearing. While the normal speed will be 170 r.p.m., they will be designed with provision for a safety runaway speed of 75% above normal. Simplicity will characterize the switchboard and controlling devices, which are of types requiring an effective minimum number of parts. The wheel-governors will be provided with remote electric control for both hand and automatic operation.

The establishment of the Southern Aluminum Co.'s plant at Whitney is transforming the site into a bustling city. While the construction of the plant is under way, it is anticipated that 2000 people will reside there, and 500 new concrete houses are being erected to accommodate the influx of population. Experienced chemists, electric and hydraulic engineers, and experts in every branch of the business will constitute the working force of Mr. Heroult, under whose able direction this comprehensive and important development will be consummated and also operated after successful completion.

## EDITORIAL

IT has been steadfastly held that the Democrats were in a minority, but recent listing of men available for Cabinet positions throws doubt on this belief.

LITERATURE, rather than ore, formed the main output of the Hawthorne silver and iron mines companies, and the Government is now prosecuting a number of eminent gentlemen as a result. It is estimated that at least \$3,000,000 was collected from the sale of 'securities,' much of this on misrepresentation, and after it was abundantly clear that there could be no profit to the stockholders. Keenly as we may regret the smirching of names honored in American history, all good citizens will rejoice that the Government is finding a way to stop the reckless promotion of worthless 'mining' properties.

ALASKAN coal mine matters are not likely to be soon settled. Engineers from the Bureau of Mines are now engaged in taking out a sufficient amount of coal from the Bering River field, to permit trial on one of the gunboats or smaller cruisers. Unfortunately, a large part of their supplies was lost while being lightered to shore and the first opening made proved to be where the coal bed thinned rapidly on passing into the hill. A second entry is now being driven. Supplies are also being sent to Knick to permit of testing the Matanuska coal, but at best the matter cannot be concluded till the spring of 1914. This preliminary work is, naturally, expensive, but will afford data upon which final conclusions can be drawn. In the meantime work by private claimants has stopped. The whole situation will be discussed at Spokane next week.

SOUTH AMERICA continues to attract attention of men capable of financing and developing great mining properties. Despite the low labor cost under which its ancient mines were operated, modern technology and improved transportation facilities are opening the way to a new era in mining. Our Boston correspondent gives this week details as to the Chuquicamata, the Chilean copper property about to be developed by Mr. A. C. Burrage and the Guggenheims. At Huallaripa, in Peru, Mr. D'Arcy Weatherbe and a party are busy examining gold placers for London clients, and in Goyaz, Brazil, Mr. R. E. Cranston is doing the same for New York investors. In the great iron ore fields of Brazil, Americans now occupy a strong position and everywhere throughout the continent to the south of us, the North Americans, as we are there called, are taking their part in building for the future.

### The Moore-Butters Decision

As to patent litigation, there is never any certainty save that of uncertainty. On another page we present in full the opinion of the United States Circuit Court of Appeals for the Third District in the case of The Moore Filter Company v. Tonopah-Belmont Development Company, a case that concerns essentially the rival claims of The Moore Filter Company and the Butters Patent Vacuum Filter Company. A reading of the decision gives at once an im-

pression of its breadth and of its sweeping character. The Moore Filter Company naturally considers it final, and certainly it is so complete, and holds so strongly against the defendants, that it might almost pass for a brief. In any future litigation over vacuum filters it is sure to be of large moment. Yet it should be remembered that the decision was rendered upon appeal, and that the lower court had found, after examination of the evidence, for the defendants. It is also true that there is, under our peculiarly muddled system of patent laws, abundant opportunity for further litigation, though, as we see it, there is small probability that this particular decision can be brought before the United States Supreme Court for review, and for present purposes it is final. It happens there is no right of appeal in patent cases to that court. It lies wholly within the discretion of the court whether or not to review a patent case. The court may, and does, refuse to consider such cases on the ground that they are not of sufficient general interest. It may, at its option, consent to review a case if there be evidence of faulty interpretation of the law on the part of the Circuit Court. In the instance under review there seems slight ground upon which to rest such an appeal, since the court addresses itself almost exclusively to the facts rather than to the law. Patent cases do, from time to time, come before the Supreme Court; but mainly because of conflicting opinions rendered by United States Circuit Courts for different districts. Since there are in all nine such courts, and the learned justices have a failing for differing, albeit "with much regret," from the dicta of their learned brethren of other jurisdictions, it is in such possible conflicting decisions that the chance of further expensive and exasperating litigation lies.

As regards The Moore Filter Company and the Tonopah-Belmont Development Company, assuming that there be no appeal in this case, the matter is *res adjudica*. Considering also that there was no concealment of the fact that the real defense was made by the Butters Patent Vacuum Filter Company, it may be fairly assumed that within the Third District the matter is also *res adjudica* as regards that company. Within the jurisdiction of another Circuit Court, the same thing would be true, as a matter of comity between courts, to the extent of the prompt issuance of a preliminary injunction. If, however, the Butters company desires to contest such an action and feels that grounds exist for defense outside of those presented in the case just decided, new evidence will permit a new fight. As a result of such a further contest, another District Court may find, as did that of New Jersey, in its favor and another appellate court may sustain, instead of reverse, the decision. Furthermore, as concerns any user of the Butters filter not privy to the suit just decided, wholly new action is necessary, and any such user may elect to defend, despite the opinion already handed down by the Circuit Court of Appeals. In such action The Moore Filter Company would occupy strong ground, but would be put to much expense, with always a chance of losing.

In the decision it will be noted that, while the Butters filter is held to infringe, it is definitely stated that the significance of the machine lies not in the form but the principle on which it works, and much is made of the even cake, and the submergence of the filtering medium. By implication this bodes trouble for manufacturers of other filters that use the same principle, though the result is accomplished by novel means. How far the courts will go in holding to this can only be determined by trial, and with nine independent jurisdictions and a multitude of devices, it is easily apparent that there is abundant opportunity for fighting. All this illustrates excellently the point discussed last week, that the present system entails hardship and unnecessary expense not only on the inventor and the manu-

facturer, but a substantial burden on industry as well. The situation in cyanidation of gold ores is serious, and any engineer must give careful thought in selecting machinery not only to technical results, but to possible damages for infringement.

We believe thoroughly in adequate protection to inventors, and no informed engineer questions Mr. George Moore's early and large contribution to technology and to metallurgical advancement. Furthermore, we hold that not only inventors but those who protect and develop a business have rights that must be safeguarded. With no sympathy whatever for patent pirates, we still hold that Mr. Charles Butters, Mr. J. V. N. Dorr, Mr. E. L. Oliver, Mr. A. M. Nicholas, Mr. C. W. Merrill, and others, have contributed mightily to the actual present conditions of advancement and should share in the profits. Mr. Moore and his friends have won a great and substantial victory. Further fighting can only result in increased costs of production and in burdening the mines. The time has come, we venture to suggest, for negotiation rather than litigation. Let the contributions of each to the general result be recognized, and terms arranged under which the men who run the mills may benefit from the continued service of all men concerned. High-grade brains, as high-grade ore, are too precious to be wasted.

### Financial Control of Copper

One of the most significant factors in the present situation is the close connection existing between some of the copper producers and the power companies, which in the past few years have marked the largest development in our industrial expansion. As an instance of this, there is to be noted the consolidation of the Butte Electric & Power Company with various similar companies in Montana through the organization of a new concern to be known as the Montana Power Company, with a capital of \$100,000,000. In the directorate will be Mr. John D. Ryan, and among his associates will be Mr. Sidney Z. Mitchell, whose name will be found in the directory of the largest public utility and power and light companies in the country. Mr. Mitchell is president and director of the Electric Bond & Share Company, a holding company, which is in turn controlled by the General Electric Company. Among the other corporations of which Mr. Mitchell is president or director are The American Gas & Electric Company, The Duluth Edison Electric Company, The Central Colorado Power Company, Kansas Gas & Electric Company, Pacific Power & Light Company, Portland Gas & Coke Company, Puget Sound Electric Railway Company, and even this is but an incomplete list of his connections. Mr. Mitchell is also a director of the Mercantile National Bank of the City of New York. Mr. C. H. Sabin, one of the directors, is also the vice-president and a director of the Guaranty Trust Company of New York, now the largest trust company in the United States. The Guaranty Trust Company, recently enlarged by the absorption of the Standard Trust Company of New York, is a member of the group of banks in New York dominated by J. P. Morgan & Company, whose interests in the Guaranty Trust Co. are represented by Messrs. Henry P. Davidson, Thomas W. Lamont, and William H. Porter, who are all partners in the house of J. P. Morgan & Company.

Financial details of this nature are of interest in this connection only as showing how great are the resources of the men who control copper at this time, and how completely the present domination renders impossible, by reason of its financial strength, a recurrence of any such disastrous conditions as prevailed a short time ago when the overwhelming copper surplus was piled up in this country and the German manufacturers reaped the profit. While

the stabilizing of the copper industry is a proper matter for felicitation, it may be questioned whether some of the further developments along the line mentioned can be so considered. Independence of action and independent individual growth are, or at least have heretofore been considered, necessary elements in our economic well-being. If one group of individuals, however financially strong, or however wisely their projects may be undertaken and conducted, are to assume a predominating place in the development of an industry so large and so necessary as the production of copper, and are to add to its production the direction of a large part of its consumption, it may well be doubted whether the stifling of independent growth which may naturally ensue will be altogether happy. No would-be copper producer unwelcome to the present controlling powers would be apt to find it possible to achieve any large degree of success. Money to develop would not be forthcoming, smelter contracts could not be made, and his progress would be effectually blocked. The capacity of the men controlling, their ability to handle the situation, and the undoubted benefit derived from what has already been accomplished are to be accepted without question; but grave responsibility rests upon the shoulders of any group of men who control necessities of life—such as the production of copper, its use in the development of power, and the distribution of that power in turn to the consuming public. The contemplation of the power so exercised must inspire its possessors with something akin to awe, and with its achievement it can only be hoped that there will come a very real sense of the responsibility and the trusteeship that is involved.

### Publicity and the Mining Congress

The American Mining Congress, which will be in session at Spokane, Washington, next week, occupies a peculiar position that is not always clearly understood. In contrast with the Mining and Metallurgical Society, and the American Institute of Mining Engineers, the Mining Congress makes its appeal for support on the basis of business rather than technology. When the old International Mining Congress gave way to the new organization, it was hoped that the latter would come to be the centre around which all mining men would rally, and the society to which they would look for aid in advancing the business of mining. To a large and increasing extent the hopes of the re-organizers are being realized. The annual sessions of the Congress are becoming steadily more important because of the men attracted and the serious import of the discussions. While in the aggregate a considerable amount of excellent material on technology has been printed in the transactions of the Congress, the officers make no appeal for papers of that character, and it is generally recognized that there are much better media for their publication. But with regard to all that relates to mining as a business, and especially in its relations to the great general public, the annual sessions of the American Mining Congress afford today the most effective opportunity for discussion. That the organization does not yet fully answer the needs of the mining men, is due to lack of recognition of its possible usefulness by the miners rather than to any failure on the part of its officers. In the United States, public opinion is the ruling power in the nation and also in the individual states. Since but a minority of our people are concerned with mines, public opinion must necessarily be at best based on inadequate information in mining matters. Only active missionary work and constant effort will prevent the enactment of laws that do grave injustice to the great basal industry that made the West, and they are equally necessary to reform abuses. It is not that the lawmakers and

those back of them who create public opinion wish to be other than scrupulously just, but they simply do not know. And for that condition no one is more responsible than the mining men, the ones most concerned. When the Federal corporation excise tax was levied, the framers of the act attempted to do justice to the mines in the matter of depreciation, but actually the matter is so involved that the most honest and well informed manager does not know how to make his returns. In the attempt to be just to workingmen, and in that effort mine operators are as much concerned as any, various states have enacted workmen's compensation laws. There is now little disagreement as to the soundness of the principle that each industry should bear its own burdens, but because of lack of knowledge, the actual laws now in force bear with great inequality on different industries. In Nevada the law differs materially from that in California and imposes heavier responsibilities and greater cost on mine operators. Either the Nevada law is too severe or that of California too lax; possibly neither is soundly drawn. In any event, it is clear that in these and other instances laws vitally affecting the mining industry are passed by men who know little of the actual governing conditions. It has often happened that such laws have been enacted at the insistence of an interested minority of men in the industry itself, and whether such pressure comes from a labor trust or an industrial trust, the effect of such self-seeking is bad. If mining men want even justice in legislation, they must spend time and effort in giving sound information to the public, the fundamental source of law.

The best means of accomplishing this is through open and frank discussions among mining men, staged in such a way as to get the public ear. A brass band may not convey much information, but it collects the crowd, and no wise speaker protests at its presence. The delegate feature of the Mining Congress, by which the President, governors, mayors, and other public officials appoint representatives to join the regular members in their deliberations, may not always result in the fittest men being chosen. It does, however, attract attention and get publicity, and upon the latter the mining men depend if sound public opinion is to be developed. At the sessions of the Congress, discussions covering topics of the widest interest, are arranged. Well prepared speakers introduce each topic and there is always time for general debate on the floor. This may result in no consensus of opinion, the Congress may never be able to agree on a resolution, though in most cases the latter proves possible, but at least the advocates and opponents of each measure have had the opportunity to present their arguments before a critical audience, and at the same time to reach the public ear. No markedly unsound argument can long escape challenge; and if wrong doctrine is sometimes preached, at worst the antidote is sent with the poison. We believe this is a good and useful work. We have watched the growth of the Mining Congress with interest and sympathy from the first day of a noisy youth to its present position of nation-wide influence, and we trust it may survive for many years of helpful endeavor. With such men, to mention only a few, as Messrs. S. A. Taylor, D. W. Brunton, Carl Scholz, John Dern, James Douglas, H. H. Gregg, Harry N. Taylor, E. B. Kirby, Falcon Joslin, John H. Jones, T. J. Grier, and S. W. Mudd actively interested, and with an honorable record of achievement, the Congress can well look to the future with confidence. The local committee at Spokane has made extensive preparation for the session of this year and the program covers many of the problems of most acute present interest. An enjoyable and useful session is certain. We shall present later an account of the meeting, but in the meantime express our felicitations on the past and extend good wishes for the future.

# Milling Plants of the Oriental Consolidated, Unsan, Korea

By A. E. DRUCKER

The gold-mining concession of the Oriental Consolidated Mining Co. covers an area of some 600 square miles on the headwaters of the Anju river, in northwestern Korea. Since the operations of the company are so extensive a number of stamp-mills and cyanide plants are required. The following account of the results secured through recent changes in construction at some of these plants will be of interest. Details of operating costs during the fiscal year 1910-1911, as given in the annual report, appeared in the *Mining and Scientific Press* of January 13, 1912.

## MAIBONG CANVAS PLANT

This plant was designed to make a saving from the mill tailing. The method of treatment consists of a preliminary classification and re-concentration of the resulting fine and

28 canvas tables. The total cost of installation was \$9461. The gross value saved in concentrate from the canvas tables, since the completion of the plant (March 11, 1912) amounts to \$5898. Gross value saved during July equals \$1696. The profit derived to August 1, after deducting all operating expenses, amounts to \$4183. By January 1, 1913, this plant will be paid for, and from that time on I estimate an average monthly net profit of about \$1150.

## KUK SAN DONG DUMP RE-TREATMENT PLANT

The total time this plant operated during the past fiscal year was 212 days, and in that time 11,953 tons dump, 88 tons Maibong, and 912 tons Kuk San Dong mill concentrate were treated. The method of treatment for the dump (sulphide tailing from old cyanide plant) consists of wash-

TARACOL REDUCTION PLANT, UNSAN, KOREA.

slime tailing on canvas-tables. Total cost of plant, which includes two cone classifiers, three Callow cone thickeners, and eight adjustable canvas tables (8 by 16 ft.) was \$1871. The gross value of concentrate saved from the canvas table has been \$9116 to July 1, 1912. The net profit equals \$3290, after deducting cost of plant, operating expenses, transportation, cyanide treatment of concentrate, and tailing losses.

## TABOWIE CANVAS PLANT

The treatment at this plant is almost identical with that at Maibong, with the exception that no Callow cones are used. The plant consists of eight cone classifiers and twenty canvas tables, which represents a total expenditure of \$4354. The gross value of concentrate saved (243 tons) from the canvas since the completion of the plant (November 18, 1911) amounts to \$5014 to July 1, 1912. This represents a total running time of five months, the plant being closed down during January and February on account of a shortage of water. The gross saving in concentrate for the month of July 1912 amounts to \$1200. Net profit to August 1, 1912, equals \$97, after deducting the cost of plant and all other expenses. From now on I estimate an average monthly net profit of \$800 to \$900.

## TARACOL CANVAS PLANT

The treatment is similar to the other plants, with the exception that the coarse product from the classifiers is treated on Wilfley tables instead of belt vanners. The plant consists of four classifiers, eight Wilfley tables, and

ing, classifying, and re-concentrating on Wilfley tables. The concentrate obtained, containing about 85% of the precious metals, is classified, re-ground (all-slimes), and the gold extracted by cyanide agitation and filter-pressing. Wilfley tailing from the concentrator plant is rejected. A description of this plant is omitted here, as it has already been described in my report for 1911. The concentrator plant (8 Wilfleys) treated an average of 56.3 tons per 24 hours of old dump material, or at the rate of 7 tons per machine. The average assay value of the Kuk San Dong re-treated dump material is \$3.14 (this does not include re-treated Maibong tailing from old cyanide plant). The results obtained on this (\$3.14) dump material are: gold extraction by re-concentrating, 85.7%; extraction from this concentrate by re-cyaniding, 63.6%; net bullion extraction from dump, 53.9%. Considering the material treated and its low value, this result is up to expectations.

The material to be treated during the coming fiscal year averages \$8.28, or \$5.14 more per ton, and this increased value should net us a good profit. Our average total expense per ton for the dump material treated was \$2.26, and this amount is less than the concentrate treatment expense (\$2.81) at the Alaska Treadwell mines, where a similar plant treats 90 tons per day using cheap electric power. Upon a total tonnage of 12,953, including Kuk San Dong dump, Kuk San Dong mill, and Maibong mill concentrate, a net profit of \$3881.14 was realized. My estimated net profit on the remaining Kuk San Dong old concentrate tailing dump, with practically all the low-grade

material re-treated, according to the results already obtained, is as follows:

Cost of treating 29,056 tons at \$2.26.....	\$65,666.56
Original cost of the plant.....	39,336.38
Value remaining in tailing (\$2.50 per ton)....	72,640.00
Total .....	\$177,642.94
Net recovery .....	63,014.42

Gross content (29,056 tons at \$8.28).....\$240,675.36

To the net recovery must be added \$13,842 as credit to be received for the plant machinery upon completing the work, so that the ultimate net profit will be \$76,836.42.

The foregoing report of the Kuk San Dong dump plant

(1912) so far amounts to about 20%. The bullion now being obtained is derived only from the re-treatment of tailing from the old cyanide leaching plant. I attribute the better results to some changes made in the treatment during the past three months. Another small air-compressor was installed, which enabled us to put into commission a fourth Pachuca agitator, allowing for a longer time of agitation and treatment. Finer grinding of the sulphide was resorted to (all passing a 200-mesh screen). The barren solution wash applied through the main filling channel of the Dehne press was responsible for the better results in filter-pressing. A preliminary treatment Pachuca agitator has recently been installed which agitates the concentrate from the Wilfley tables with lime-water and air. The concentrate is now alkaline before passing to the tube-mill to

TABOWIE MILL.

CANDLESTICK MILL.

gives the results for the fiscal year ended June 30, 1912. The results for the first three months of the fiscal year 1913 have been most encouraging. They are as follows:

	Tons treated.	Gross content.	Bullion recovery.
July 1912.....	1,529	\$8,219.23	\$6,712.57*
Aug. " .....	2,060	7,753.47	7,103.80†
Sept. " .....	1,956	7,598.45	5,905.78
	5,545	\$23,571.15	\$19,722.15

JULY, AUGUST, SEPTEMBER 1912

Average value of material per ton treated.....	\$4.25
Average actual net bullion extraction, per cent....	76.47‡
Total time operating, days.....	73
Capacity per 24 hours, tons.....	76
Cost of treatment per ton.....	\$1.75
Net profit obtained .....	\$10,000

The following is an average analysis of the old cyanide tailing dump (now being re-treated) before it had become weathered and oxidized:

MAIBONG CONCENTRATE.	%	KUK SAN DONG CONCENTRATE.	%
Gangue .....	62.96	Gangue .....	50.60
Pyrite .....	17.60	Arsenical pyrite .....	27.04
Arsenical pyrite.....	17.00	Marcasite .....	13.12
Iron oxide .....	2.21	Galena .....	9.14
Galena .....	traces	Sphalerite .....	traces
	99.77		99.90

(Gangue consists mainly of quartz.)

It is easy to imagine the difficulties likely to be encountered with such material after standing for eight to ten years before receiving a second cyanide treatment.

The increase in extraction over the previous fiscal year

\*Includes \$1703.02 = bullion from May and June slag.

†Includes \$896.25 = bullion from July slag.

‡Does not include \$1703.02 July slag credit, which should have been credited to the previous fiscal year.

be ground in cyanide solution. This effects a material saving in cyanide and prevents to a large extent the fouling of the solutions, and better extraction consequently results. The present foreman of the plant, G. C. Evans, is to be congratulated upon his good work.

TARACOL CYANIDE PLANT

The re-grinding plant was completed about the middle of May 1912, but did not operate steadily until the latter part of the month. Even the following month of June was occupied mainly in 'breaking in' Koreans to the new work.

KUK SAN DONG REDUCTION PLANT.

Our mechanical troubles were due chiefly to inexperienced labor. Because of several days of lost time during June it was necessary to run several charges of concentrate into the old leaching plant to prevent an accumulation of concentrate at the Tabowie and Taracol mills. Consequently there were two plants' running until June 15. The total operating expense for both plants was included in one, and charged up against the new cyanide re-grinding plant. Also the total bullion clean-up was included as one and credited to the new re-grinding plant. The total concentrate for June treated in both plants was 2228 tons, which was valued at \$55,993. The bullion extracted from this was

# Geology of the National Mining District, Nevada

By ALEXANDER N. WINCHELL

The National mining district is about 75 miles north of Winnemucca, which is the county seat of Humboldt county, Nevada, on the Southern Pacific railway about 400 miles east of San Francisco. The district is in the northern part of the Santa Rosa mountains, about 10 miles south of the Oregon-Nevada boundary line. These mountains form the eastern boundary of the valley of the Quinn river, whose waters flow southwest and disappear in the Black Rock sink. The Quinn River valley, like many others in the West, is nearly flat, sloping gently upward toward the mountains on either flank, and still more gently downward along the course of the valley to the southwest. The district is accessible over good mountain roads from the county seat, and

eruptions which have been described in southwestern Nevada by Spurr<sup>1</sup> and others. In a brief study of the relationships of the various volcanic rocks near National, I found evidence of the following succession, beginning with the oldest: older basaltic rock, older rhyolite, older andesite, later rhyolite and later andesite, later basaltic rock. That there are two series of volcanic rocks of different age in the district is shown by the difference in altitude and difference in physical conditions of the rocks. The older series consists of rhyolites and subordinate andesites, which form flows and more or less bedded tufts now, in the large part, highly altered. The beds and flows of the older series have been tilted and truncated by erosion. The later series cuts through the older rocks and lies on this old erosion surface; it consists largely of basaltic flows with subordinate intrusions and extrusions (surface flows and volcanic tufts) of rhyolite and andesite. On Charleston hill and Buckskin mountain flows of obsidian and later rhyolite are reported, lying above later basaltic rock. Still higher stratigraphically

WESTERN NEVADA.

there is at present an automobile stage, carrying daily mail, and making the trip each way in one day. The elevation of the Quinn River valley is about 4200 ft. above sea-level. The National mining district in the mountains on the eastern boundary of the valley occupies an area whose elevation varies from 6000 to 7000 feet.

## GENERAL GEOLOGY

The north end of the Santa Rosa mountains is occupied by a portion of the great basalt flows which extend from this region northwestward to the Columbia river, and northeastward across the plains of southern Idaho, nearly to the western boundary of Wyoming. Elsewhere the great lava plains of Oregon and Idaho are occupied chiefly by basalt flows, but in this mining district near the southern boundary of the Columbia river lavas, the volcanic rocks are not of uniform composition; they include such acid rocks as rhyolites, as well as andesites and more basic basaltic rocks. The National mining district is therefore, in a certain way, a connecting link between the more uniform lava flows of the north and the diversified volcanic

NATIONAL IN 1910.

the latest flows are thick and basic. North of Eight-mile creek the later volcanic series consists of more than 2000 ft. of flows and tufts dipping gently to the east.

The succession of volcanic rocks as worked out by various authors in regions near, and probably genetically connected with the National district, and the assumed relations between these areas, are summarized on the following page.

The oldest rocks discovered in the immediate vicinity of National are basaltic fragments enclosed in the older rhyolite. It may be inferred that the rhyolite had cut through basaltic flows in reaching its present condition. These old flows were not recognized in the field and apparently do not reach the surface near the National mine. The fragments are dark and rather basic, and the rock may be augite andesite instead of true basalt. They have not been examined microscopically. The next younger volcanic rock is a hornblende andesite, which shows evidence of much alteration. That the andesite did not follow promptly after the rhyolite is shown by the relations exhibited in an adit on Radiator hill, where andesitic tuff overlies an inclined and much weathered surface of older rhyolite; the surface dips about sixty degrees east. A hornblende dacite of uncertain age is closely associated in its rare occurrences with the older andesite.

The later rhyolites (and andesites) contain inclusions of a basic rock which is either basalt or augite andesite. It may represent basaltic flows younger than the older andesite (and of course older than the later rhyolite), or it may represent the same basaltic flows of which fragments are found in the older rhyolite. Like the latter, its character as a true basalt is questionable; it may well be an augite andesite.

The relative age of the later rhyolite and later andesite has not been fully established, but the andesite is considered the younger, since it contains fragments of rhyolite which are apparently not from the older rhyolite. It also con-

tains at the Shiloh group fragments of an older andesite. In the same region a single outcrop of dacite is associated with the later andesite.

Augite andesite in dikes, sills, and flows is clearly later than the older series, but its relation to the younger series is open to question. It may be the older member of the younger series, and identical with the basaltic rock occurring as inclusions in the later rhyolite.

The later basaltic rock has not been carefully studied, but it is supposed to be a true basalt. On Charleston hill, and on Buckskin mountain a flow of obsidian succeeded by rhyolite is reported above the later basalt. North of Eight-mile creek the latest flows are basaltic in character.

## PETROGRAPHY

The igneous rocks of the National district include rhyolitic obsidian, andesitic obsidian, rhyolitic tuff, andesitic tuff, rhyolite, dacite, hornblende andesite, augite andesite, hornblende augite andesite, and probably basalt.

The rhyolitic obsidian apparently forms a dike in the face of an adit of which the portal is about 500 ft. northwest of the Silver Slipper claim. It is of a greenish gray color, and contains crystals of abnormal (or high temperature) orthoclase, plagioclase, and quartz. Grayish black obsidian, supposed to be rhyolitic, is reported from the top of Charleston hill.

Andesitic obsidian of a dark gray color occurs in dike-like form at the southeast corner of Fairview No. 1 claim. It strikes N.70°W., and dips steeply to the south. It contains numerous crystals of labradorite feldspar in a dark brown groundmass. An obsidian containing biotite phenocrysts is reported from Buckskin mountain.

Rhyolitic and andesitic tuffs and breccias are not uncommon in the region; they present no features of special importance. In the immediate vicinity of National they belong chiefly to the older series.

Rhyolite of the older series is usually much altered; when the primary minerals are still recognizable they include abundant orthoclase and quartz with some plagioclase and little accessory ilmenite. A few samples contain some green hornblende. Secondary minerals often present include chlorite, leucoxene, quartz, calcite, sericite, kaolinite, epidote, hematite, and limonite. The rock often contains disseminated pyrite, and another sulphide of silver-gray color and

metallic lustre which is probably arsenopyrite. These sulphides, as well as some of the calcite (or related carbonate), may be magmatic in origin.

Rhyolite of the later series has not been studied microscopically, but it is relatively fresh and contains abundant unstriated feldspar and glassy quartz.

Andesite of the older series is an important rock at National, being one of the wall rocks of the chief vein of the district. Like most of the rocks of the region, it is commonly fine grained, requiring the highest magnification to determine the mineral composition. It is either felsitic or porphyritic in texture, part of the groundmass frequently being glassy, and the phenocrysts usually small. It is sometimes amygdaloidal, and nearly always considerably altered. The small phenocrysts of plagioclase range in composition from basic labradorite to acid andesine. The groundmass is commonly composed of fine lath-shaped plagioclase slightly more acid than the phenocrysts, green hornblende or chlorite, more or less ilmenite, and rock glass. Rarely remnants of biotite may be discovered. Secondary minerals include chlorite, leucoxene, sericite, kaolinite, quartz, calcite, hematite, limonite, and pyrite. The remarkable feature of the andesite is the abundance of calcite (or a related carbonate, either dolomite, siderite, or ankerite). In samples in which the mass of the rock is much altered it is a natural inference that the calcite is secondary, but this inference is not so easily drawn for those samples in which the plagioclase and other primary minerals are quite fresh. Fig. 1 illustrates the appearance in thin section of such a rock from the face of the Atkinson adit on the Fairview claim. As shown in the figure the plagioclase is quite fresh and clear. Some of the crystals still retain sharp crystal outlines, and yet these crystals and ilmenite (or magnetite) are embedded in fine grained calcite. Such a condition forces one to consider seriously whether the calcite is not of primary origin, that is, crystallized directly from the magma. Magmatic calcite has been described by Adams,<sup>2</sup> Törnebohm,<sup>3</sup> Holland,<sup>4</sup> Emerson,<sup>5</sup> and Workman,<sup>6</sup> nearly always in nepheline syenites or in rocks associated with nepheline syenites. In the andesite from National, it is clear that part of the calcite in its present position is of

‡J. E. Spurr, *Jour. Geol.*, Vol. VIII, 1900, p. 621.

later origin than the feldspar, since it occurs in fractures running irregularly through the plagioclase. Such calcite-filled fractures not only cross the rare phenocrysts but traverse also the microlitic groundmass. Furthermore, the amygdules scattered through the rock are filled with calcite formed in two stages; the first formed being clear, colorless, and sometimes spherulitic, the second being cloudy and yellowish, probably from limonitic stain. On the other hand, there is not the slightest indication that the calcite is confined to, or is even more abundant near, fractures than in the rock as a whole. If the calcite, especially that in microscopic veinlets and amygdules, is the result of later alteration, that alteration must have occurred under conditions such that the plagioclase and magnetite were remarkably stable, while the rest of the rock was removed almost completely. It is well known that this will not occur under ordinary weathering conditions, and that, on the contrary, the plagioclase of the Columbia river basalts alters readily under such conditions, and that one of the products of such alteration is calcite. It is also true that ordinary rock samples illustrating the production of calcite from feldspathic rocks probably under conditions of moderately high

in cold acid and has indices somewhat higher than those of calcite. This rock seems to furnish another example of primary carbonate, since the fresh unaltered minerals include not only plagioclase and magnetite, but also brown hornblende and apatite. The carbonate seems to have ceased to crystallize after the magnetite, but as early as the feldspar. Quartz was the last mineral to complete its crystallization and fills interstices between the other minerals. The rock is a carbonated hornblende dacite. The relation of the carbonate to the other minerals of this rock is shown in Fig. 2.

The augite andesite of National has been often called basalt because it differs sharply in appearance from the hornblende andesite of the same district, while it resembles closely a true basalt. The rock is essentially different from a true andesite, and therefore the name augite andesite, which implies that the rock is a variety of andesite, is distinctly objectionable. I would suggest that such rocks be called auganite. The relation in chemical composition between andesite, auganite, and basalt may be shown by comparing the averages computed from all available complete analyses.

FIG. 1. UNALTERED LATH-SHAPED PLAGIOCLASE WITH SHARP CRYSTAL OUTLINES EMBEDDED IN CALCITE. FAIRVIEW CLAIM, NATIONAL, NEVADA. CROSSED NICOLS.  $\times 30$ .

pressure and temperature furnish nothing like the andesite found in National. On the contrary, in such rocks the calcite is clearly derived at least in part from the alteration of the feldspar. It seems probable, therefore, that the calcite in the andesite at National is largely of magmatic origin.

Andesite of the later series has not been studied microscopically, but it is relatively fresh, contains little or no calcite, and consists largely of plagioclase and hornblende, commonly with rock glass. Some of the samples contain fragments of an older andesite, of a basaltic rock, or of a rhyolite.

Dacites are rare in the National district, but the two samples discovered seem to represent two periods of intrusion. One is closely associated with the later andesite, and, like the latter, is fresh and contains little or no calcite; it is a porphyritic rock containing small phenocrysts of quartz, andesine, and biotite in an extremely fine grained groundmass of the same minerals with much rock glass. It is a biotite dacite. The other is closely associated with the older andesite and like the latter contains abundant carbonate. Unlike those of the older andesite, the plagioclase phenocrysts and the smaller crystals of the groundmass are fresh and unaltered with sharp crystal outlines. The rock contains abundant feldspar, some quartz, light brown hornblende, magnetite (or ilmenite), apatite, and much carbonate, which is probably ankerite, since it does not effervesce

FIG. 2. DACITE, NATIONAL, NEVADA. THE BLACK MINERAL IS MAGNETITE OR ILMENITE, THE ELONGATED GRAY MINERAL WITH CLEAVAGE LINES IS BROWN HORNBLLENDE, THE IRREGULAR GRAY GRAINS ARE ANKERITE, THE WHITE GROUNDMASS IS A MOSAIC OF PLAGIOCLASE AND QUARTZ. ONE NICOL.  $\times 60$ .

Auganite is a volcanic rock consisting essentially of basic plagioclase and pyroxene; the plagioclase is usually labradorite, but may be more basic; andesine marks a transition toward andesite. The pyroxene is often augite, but hypersthene, bronzite, diopside, and even enstatite replace the augite more or less completely in some types. Hornblende and mica are not common, nor abundant. Andesite consists of acid plagioclase (andesine or oligoclase) with hornblende or mica or pyroxene. Having provided the new name auganite for rocks ordinarily called augite andesite, it is possible to use the latter name for rocks which are actually varieties of andesite, and consist essentially of acid plagioclase and pyroxene. The close relationship in composition between augite andesite as thus defined and other andesites is clearly shown in the following table. Auganite at National forms dikes and flows which are dark colored and fine grained. In places they are amygdaloidal, the cavities being filled by layers of chlorite, calcite, and quartz, commonly formed in the order indicated. Rarely the rock contains accessory hornblende. Some samples contain abundant calcite and some pyrite. Part of the calcite seems to be of magmatic origin, but the evidence is not decisive.

Basalt is reported in flows stratigraphically above the foregoing rocks. I have not studied it.

Hornblende and mica andesite: average of 34 analyses, from data of Daly, *Proc. Am. Acad.* XLV, 1910, p. 223.

Augite andesite: average of 23 analyses from data of F. W. Clarke, U. S. Geol. Surv. Bull. 419, 1910, Rosenbusch, 'Elem. Gest.', 1910, p. 382, and Osann, 'Chem. Petrog.', II, 1905. The name is here restricted to volcanic rocks containing acid plagioclase and pyroxene.

All andesite: average of 57 analyses, from data of R. A. Daly (*loc. cit.*), F. W. Clarke (*loc. cit.*), Rosenbusch (*loc. cit.*), and Osann (*loc. cit.*). Auganites excluded.

Auganite: average of 73 analyses, from data of F. W. Clarke, U. S. Geol. Surv. Bull. 419, 1910, Rosenbusch, 'Elem. Gest.' 1910, pp. 378, 382, and Osann, 'Chem. Petrog.', II, 1905. Rocks containing acid plagioclase or orthoclase are excluded and 12 olivine-free basalts are included.

Basalt: average of 161 analyses, R. A. Daly, *Proc. Am. Acad.* XLV, 1910, p. 224.

#### ORE DEPOSITS

The ore deposits of the National district are all in quartz veins largely confined to the older volcanic series. There are two types of ores present: one is characterized by copper, lead, and silver, and the other by gold (with silver).

The veins containing the base ores were produced after the extrusion of the older rhyolite, and probably before any of the later rocks; they cut the rhyolite and are not known to extend into the later rocks. The veins formed at this time contain a considerable variety of minerals; the chief gangue mineral is quartz accompanied in places by subordinate quantities of calcite and a little sericite; the chief ores include chalcopyrite, arsenopyrite, pyrite, bornite, stibnite, galena. They often contain an important amount of silver as well as copper and lead. Under favorable conditions they would yield fair returns, but on account of the comparative isolation of the district they have not yet produced any considerable amount of shipping ore.

Gold ore is the important resource of the district. The vein of the National mine contains phenomenally rich gold ore in quartz. It occupies a fissure which was produced later than the veins containing base ores, and later than the older andesite. Faulting along this fissure has lowered the andesite (which probably formerly overlay the older rhyolite) of the hanging wall to a position on a level with rhyolite in the foot-wall. The fissure was filled by quartz containing argentiferous gold or electrum with small amounts of pyrite and stibnite, and very little stephanite, native arsenic, galena, sphalerite, and chalcopyrite. After the formation of the ore, faulting continued along the vein; consequently, the ore is much broken and granulated, and rolled fragments are often found in the fault gouge. This post-mineral faulting movement along the vein occurred after the extrusion of the auganite, since fragments of this rock are now in the fault gouge. The metallic part of the ore consists of gold and silver usually in the ratio of about 1 to 1, as in electrum. The latter is intimately intergrown with finely granular quartz, and partly enclosed by elongated prisms of quartz rudely parallel or radial. Stibnite and native arsenic intergrown with the quartz give it in places a dark gray to black color. The sulphides in this vein are intergrown with the quartz, but (except stibnite in a few cases) are not so closely associated with the electrum. Even the pyrite

is rarely if ever directly intergrown with the gold. In occasional samples the gold ore is broken and recemented by white quartz containing a little pyrite. There is little evidence of secondary enrichment, and no abundant formation of secondary minerals of any kind in the National vein, but small quantities of the following secondary minerals have been observed: calcite, orpiment, realgar, sericite, limonite, and pyrrargyrite. Marcasite, native gold, and polybasite are reported as secondary minerals, but I have not observed them.

The ore occurs in a shoot of rather indefinite boundaries which has been proved to extend on the dip for a distance of about 700 ft. and on the strike for a distance of 400 ft. The shoot is not known to extend to the surface at any point, and for about 60 ft. from the surface downward the vein contained some silver, but no high-grade ore. No placer mines have been discovered in this vicinity, although erosion has been at work cutting down the surface and the outcrop of this vein for some time. It seems probable that the bonanza ore-shoot never reached the surface of the earth, and also that the upper portion of the vein which has been removed by erosion did not contain any similar lens of high-grade ore. Most of the ore from the mine is worth from \$30 to \$60 per pound, and the total production since the discovery of the lode in 1907 is reported to have been between \$3,000,000 and \$4,000,000.

#### ORIGIN OF THE ORE

The problem of the origin of such ore is of great importance, as well as of a peculiar fascination, because it has engaged the attention of so many eminent students of ore deposits without receiving any satisfactory solution.

It is commonly believed that many ore deposits in veins have been formed by precipitation of metals, sulphides, or other compounds from flowing water or from flowing aqueous vapor. It seems reasonable to believe that such a mode of origin would produce a banding or crustification in the ore. At Steamboat Springs,<sup>7</sup> Nevada, where such a process is now forming deposits of stibnite, pyrite, metastibnite, and silica, and unrecognized minerals containing gold, silver, copper, lead, arsenic, and other metals, crustification on the walls of the fissure is distinctly visible through the recent sinter.

At National crustification is not uncommon in the quartz of the main vein, but it is wholly lacking in the high-grade gold-quartz, so far as I observed. It seems improbable, therefore, that precipitation occurred from a flowing fluid. I would suggest that the gold quartz was precipitated, not from a thin aqueous solution, but from a viscous, and perhaps gelatinous mass which occupied the fissure in much the same way as an igneous magma fills an opening in country rock. The amount of motion during crystallization may have been no greater in the former instance than in the case of the magma.

The constituents of the viscous mass which formed the National vein may be inferred (from the components of the vein) to have been silica, gold, silver, and very little antimony, arsenic, iron, and sulphur. In accordance with generally accepted views, it is believed that these constituents did not exist merely in mutual solution, like those of a magma, but that they existed in solution in water or aqueous vapor. It is considered probable that the amount of water present was small, and that supersaturation was prevented by the presence of certain compounds which increase the solvent power of water, or may be themselves efficient solvents. Such compounds are carbon dioxide and alkaline sulphides. The present condition of the wall rocks, with abundant carbonates apparently both primary and secondary in origin, renders it very probable that carbon dioxide existed in the ore-forming solution. It is from chemical considerations that a belief in the existence of alkaline sulphides in the solution is derived.

In seeking for a solvent of gold in the National vein

<sup>7</sup>G. F. Becker, U. S. Geol. Surv. Mon. XIII, 1888, p. 331-353; W. Lindgren, *Trans. Am. Inst. Min. Eng.* XXXVI, 1906, pp. 27-31; J. C. Jones, *Science*, XXXV, 1912, p. 775.

it must be remembered that the ore contains not only gold, but also silver. It is clear that the two metals solidified simultaneously, and therefore from a single solution. Consequently it is necessary to find a solvent for both. Hydrochloric acid under pressure less than 100 lb. per square inch and at moderately high temperatures (about 120°C.) dissolves gold,<sup>8</sup> but is not a solvent for silver. Nitric acid dissolves silver, but does not affect gold. Sulphuric acid attacks silver, but is not a good solvent for gold. In short, there is no common mineral acid which is a solvent for both metals. On the contrary, alkaline sulphides, even when present in small amounts, are efficient solvents for gold, while silver sulphide is soluble in water<sup>9</sup> alone at temperatures as low as 89°C. Such solutions are also solvents of iron, antimony, arsenic, lead,<sup>10</sup> zinc, and copper, all of which are found in the National vein in sparse to rare primary minerals. Moreover, Lenher, of the University of Wisconsin, finds that an alkaline sulphide solution of gold is stable<sup>11</sup> under a considerable variety of conditions, whereas most other solutions are relatively very unstable, especially in the absence of oxidizing conditions.

Accordingly, it is probable that the solutions which filled the National fissure contained alkaline sulphides, and that these sulphides kept the gold and silver in solution.

If such a vein-magma did at one time fill the National fissure it would certainly slowly cool, and perhaps at the same time slowly come under decreasing pressure on account of slight upward movement and surface erosion. Supersaturation would finally ensue, and centres of crystallization would be established. On account of the high tenor of silica, quartz would probably be one of the earliest products of crystallization. The immediate result of the formation of quartz would be the liberation of water, previously combined with the silica in the condition of unconsolidated opal. Under suitable conditions of temperature and pressure, the water would promptly combine with carbon dioxide to form carbonic acid. Alkaline sulphides are wholly unstable in the presence of any mineral acid, including carbonic acid. Alkaline carbonates and hydrogen sulphide would probably be produced. The destruction of the alkaline sulphides would remove the solute for the gold and silver, and these would be precipitated. In the absence of gold the silver would probably combine with sulphur of hydrogen sulphide to form argentite. But in the presence of gold it seems to form an alloy (electrum) with the latter, rather than to decompose the sulphide.

Whether the precise chemical processes<sup>12</sup> involved have been correctly stated or not, it seems clear from the mode of occurrence that the electrum was precipitated from a solution containing large proportions of the precious metals, and that it was precipitated with the earliest products of crystallization from that solution. Alkaline sulphides are known to be remarkably efficient solvents, and they are regarded as the most probable solvents in this case; their destruction, probably to form carbonates, is believed to have caused the precipitation of the electrum.

The existence of pockets or lenses of high-grade ore (electrum quartz) may be due, in part at least, to the process of crystallization. The electrum must be precipitated around those spots where centres of crystallization liberate the water. The noble metals may have been fairly uniformly distributed through the vein magma at the beginning of crystallization. As soon as crystallization commenced the metals would diffuse toward the centres of crystallization. Thus the electrum would form local masses in a vein quartz elsewhere nearly or wholly barren. After the precipitation of the electrum, the alkaline carbonates

and sulphuretted hydrogen would escape from the crystallizing mass upward through the unsolidified portion (if any still existed) and outward into the adjoining rocks. These compounds would produce the secondary carbonates (calcite, ankerite, siderite) and sulphides (pyrite) which are found in the country rocks.

The process here outlined as a possible mode of origin of the electrum quartz of the National vein would have as consequences the crystallization of electrum with the earliest quartz formed, and the existence of cavities in the ore due to the escape of water and gases. As a matter of fact, a careful study of the ore makes it plain that the electrum crystallized with the first formed quartz which is finely granular, and is scanty or absent in the quartz of later crystallization, including that which lines vugs. Also, it is a fact that vugs are fairly abundant in the high-grade ore.

As a result of a study of the National vein, I have one other suggestion to offer in regard to the origin of the ore. Geologists and engineers often speculate regarding the origin of ore-shoots. As I interpret the National vein, it furnishes an excellent illustration of a paragenetic<sup>13</sup> ore-shoot due to a structural feature, but not a structure cited by Van Hise.<sup>14</sup> It is a 'shoot of variation'<sup>15</sup> not due to any chemical effect of wall rock nor to intersecting veins. The National vein strikes about north and south and dips about 50° to the west. Near the middle of the West Virginia claim the course changes, going southerly from nearly due south to south 25 to 30° east. The opening of the mine on different levels to a depth of about 500 ft. shows that this bend in the course of the vein pitches to the south so as to make an angle of perhaps 20° with the line of dip of the vein. Careful study of the striations on the walls of the vein has shown that the general direction of the faulting motion was nearly straight down the dip. Therefore, the direction of motion of the hanging wall makes an angle of about 20° with the pitch of the curve in the vein. It may readily be seen that the result of such conditions would be a tendency to relieve the pressure of the hanging wall, to produce less fault gouge, and to make an open space in the fissure north of the bend. Another result to be expected is a breaking of the hanging wall. All of these results are realized in the National vein. And it is in the open space thus produced that the ore-shoot of the mine is found. This shoot pitches in the same direction as the bend in the vein; it terminates to the south near the bend, and extends rather indefinitely to the north for a horizontal distance of about 400 ft. Since the pitch of the ore-shoot is not parallel with the direction of faulting motion along the vein as shown by striation, this shoot is not in harmony with Clayton's law<sup>16</sup> that such parallelism usually exists.

ACCORDING to the United States Geological Survey, there was no production of cobalt, molybdenum, nickel, rutile, or tantalum in this country during 1911. The United States cobalt supply comes from Cobalt, in Canada, imports for last year being 579,520 lb., worth \$48,104. Imports of molybdenum and ferro-molybdenum were 8.5 tons, valued at \$11,409. All nickel used comes from Sudbury, in Canada, the imports being 29,829,268 lb., valued at \$4,022,716. Ferro-titanium amounting to 51.17 tons, and worth \$22,700, was imported for consumption. A considerable quantity of tantalum wire was imported from Germany in 1911, for making incandescent electric lamps, but the quantity and value is not published.

PRODUCTION of gold in Russia during the last four years has increased over 50%, or from 22,275 poods to 35,084 poods per year, a pood (36.11 lb.) of gold being worth about \$9000 according to the fineness.

# The Gitsham Process

This new variation of the cyanide process is attracting a good deal of attention in Australia. The *Journal* of the Chamber of Mines of Victoria, makes the following statement regarding it: A subject of interest to the mining community is the process of the Gitsham Gold Extraction Co. It is claimed for this process that it will extract gold from refractory materials where the cyanide process has wholly or partly failed. Antimony and copper ores are readily treated by the solvent, which is a weak solution of hydrocyanic acid. The company has treated at a profit about 4000 tons of material at Costerfield, Burke's Flat, and Clonbinane, which has been a stumbling block to many cyanidizers. Experimental work on pyritic tailing from various parts of the Commonwealth has shown excellent results, a notable case being tailing from Randall's, Western Australia, which needs no comment. Unlike the cyanide solution, the Gitsham solvent is a weak acid, and it is claimed that owing to this fact material can be treated by leaching which otherwise would require agitation. The percentage of regeneration of the solutions, it is stated, is high, and averages from 40 to 50% of the chemicals used. The company claims that, given on ore partly amenable to the cyanide treatment, their process will give an increased extraction at a lower cost; and even on clean material the costs of chemicals are less, the only exception being on ores containing carbonates of lime, and so far this difficulty has not been overcome. As this type of material is very rare, it is not a serious matter. The control and testing of the solvent is soon learned by the man of average intelligence. The company has been doing experimental work for the past eighteen months, and is now open to the criticism of the metallurgical world.

The following supplementary details were given in a recent issue of the *Kalgoorlie Miner*: The process consists of the use of an acid solution formed by the combination of potassium cyanide and sulphuric acid, giving rise to hydrocyanic acid. Its strength varies from 0.05 to 0.1%, and is worked on the same system as ordinary cyanide. The solutions are allowed to percolate in the ordinary way, but before passing through the extractor box they are drawn off into a solution of limewater, which regenerates the cyanide and makes the solution ready for precipitation. Should the solutions be used in the weak state, a little cyanide is added at the head of the zinc-box and the solution brought up to about 0.08%. After passing over the zinc the solutions are again made acid and applied to the ore.

The following equations show what the inventor believes really takes place:

after the zinc-box:

The metallurgist of the company claims that all copper ores, likewise antimony, bismuth, and arsenic, are insoluble, and do not affect the solution and its selective action for the precious metal. Even the most refractory copper carbonate, with mixed oxides, has been successfully experimented on. About four thousand tons of ore, containing antimony and copper, have been treated by this process for a yield of £1600 worth of bullion, of an average value exceeding £4 per ounce.

Although very delicate, the process is easily controlled by a chemist, the important feature being the combination point of KCN and H<sub>2</sub>SO<sub>4</sub>. Some ores have quite enough acidity to generate with the cyanide the acid. When the latter is in excess it is removed or neutralized. Where not present, the use of sulphuric is resorted to. The inventor (Mr. Gitsham) claims to be able to treat ores which have before not been amenable to the cyanide process. Costs are from 3 to 6s. per ton on the most refractory

types. The process has been patented in the principal countries of the world, and the shareholders have decided to raise the additional capital necessary to introduce it in mining fields outside the Commonwealth. With this object in view, G. Gitsham and T. H. Davies are shortly leaving for London. As far as Australia is concerned, the company announces that they are prepared to deal with mine-owners on a royalty basis.

The suggestion recently made by W. D. Williamson in a communication to the *Journal* of the Chemical, Metallurgical & Mining Society of South Africa, is of interest in this connection. Mr. Williamson states that the addition of sulphuric acid to a solution containing the double cyanide of copper will cause the following reaction:

The insoluble copper cyanide can be separated by filtration, and the filtration neutralized by a slight excess of alkali. It is obvious, however, that there is still cyanogen in the copper precipitate which ought to be recovered if possible. If the precipitate be suspended in water, and treated with hydrogen sulphide, the following reaction occurs:

The solution resulting from filtration of the mixture can then be neutralized with alkali and used as solvent for fresh ore. The two reactions can be combined by adding sodium sulphide and the requisite amount of acid to the cupriforous cyanide solution, with this reaction:

The precipitated copper cyanide carries down with it the precious metals and can be collected, dried, and shipped to the smelter. The clear liquor is then neutralized with a slight excess of alkali to combine with the free HCN.

An obvious drawback of both of these processes is that any attempt to neutralize an acid sulphate solution by the addition of milk of lime will cause the formation of a copious precipitate of CaSO<sub>4</sub>·2H<sub>2</sub>O, which occludes considerable quantities of cyanide and which is too fine grained to permit filtering and washing unless the solution is kept cold and allowed to stand several days during precipitation. Since the hydrate of calcium is only slightly soluble in water, being less soluble than the sulphate, any attempt to neutralize in this way would greatly dilute the cyanide solution. It might prove feasible, however, to use dried or ground slaked lime for neutralizing, drive off and collect the HCN gas, and allow the sulphate solution to run to waste, or to otherwise modify the process so as to reduce it to a better working basis. The article on the regeneration of cyanide solution by B. G. Nicholl in the *Mining and Scientific Press*, March 16, 1912, and its discussion by R. P. Wheelock in the issue of April 6, will be of interest in this connection, as will the description of the cyanidation of antimonial tailing in the Hillgrove district of New South Wales, given in our issue of June 29, 1912.

ONLY four states had a mineral output in 1911 valued at less than \$1,000,000, and 10 states had a production valued at over \$50,000,000 each. No state or district appears to have a monopoly of the mineral industry. Pennsylvania produced a total mineral yield more than one-fourth that of the whole United States, leads in coal, cement, and stone; Minnesota leads in iron ore; Arizona in copper; Ohio in clay products; California in petroleum and gold; Missouri in lead and zinc; and Nevada in silver. The centres of production are ever shifting.

AN American company is being formed to develop a coal deposit on the Guasare river, in the Guajira peninsula, Venezuela. The coal has been pronounced equal to the best American steaming coal and practically free from sulphur, which is usually present in Venezuelan coal. The quantity of coal available seems to be enormous, but there may be some difficulty in providing cheap transportation to deep water.

## Construction of Triangulation Stations

By E. R. RICE

Having occasion recently to lay out a fairly extensive mine triangulation system, I designed the type of station here described, which for permanence, efficiency, and ease, and low cause of construction leaves little to be desired. In all, eighteen stations were put in, in two days time at a total cost of \$24.50, subdivided as follows:

Labor, 2 men, 2 days, at \$3.....	\$12.00
¾-in. black pipe, 36 ft.....	4.50
¾-in. black pipe, 90 ft.....	6.30
Portland cement, 150 lb. at \$1.10.....	1.65
Paint .....	0.05

Total .....\$24.50  
or a cost of \$1.34 per station.

The principles of construction of the station are evident from Fig. 1. It consists essentially of a 2-ft. piece of  $\frac{3}{4}$ -in.

FIG. 1.

pipe, set 18 inches in the ground and imbedded in concrete. A piece of  $\frac{3}{8}$ -in. pipe, 5 ft. long, is set in the  $\frac{3}{4}$ -in. pipe when observations are being made on the station, and, in fact, the  $\frac{3}{8}$ -in. pipes are left in the stations as long as surveying is being carried on. These  $\frac{3}{8}$ -in. pipes exactly fit the  $\frac{3}{4}$ -in. station pipes. If no surveying is to be done for any length of time, the  $\frac{3}{8}$ -in. pipes should be taken out and regular  $\frac{3}{4}$ -in. caps screwed on the station pipes. These caps should be marked, by means of dies, with the number of the station and its elevation.

The 5-ft. lengths of  $\frac{3}{8}$ -in. pipe are painted as follows: the bottom 2 ft. is painted black, the next 1 ft. white, the next black, and the next white. The black end is inserted in the station, and as the station pipe that projects above the cement is painted black, the lower edge of the first white division of the  $\frac{3}{8}$ -in. pipe coincides with the top of the  $\frac{3}{4}$ -in. pipe and there results a signal composed of alternate black and white divisions, on which to make observations.

In putting in the stations, the most important point is to get the  $\frac{3}{4}$ -in. pipe vertical, so as to eliminate errors due to eccentricities of station. This is accomplished by means of the apparatus shown in Fig. 2. This is made of  $\frac{3}{8}$ -in. pipe, T's and L's as shown. The end *C* is inserted in the  $\frac{3}{4}$ -in. station pipe, when the station pipe is ready to be concreted in the hole. There is a punch-mark on the top of the nipple *A*, and when the plumb-bob *B* is exactly over the punch-mark, the pipe *CD* is truly vertical.

The location for the punch-mark on the nipple *A*, Fig. 2, is best found as follows: a piece of  $\frac{3}{4}$ -in. pipe, 2 ft. long, is connected to two short nipples, *N* and *N'*, by means of two L's, as shown in Fig. 3, and the fittings screwed up tight. The nipple *N'* is then tightly clamped in a vise, and the 2-ft. pieces of pipe made approximately vertical by turning the L *E* on the nipple *N*, and the L *E'* on the nipple *N'*. The plumb-rod shown in Fig. 2 is then inserted in the 2-ft. length of  $\frac{3}{4}$ -in. pipe and rotated in it. If the bob *B* remains over the same point on the nipple *A* throughout a complete revolution, then the point directly under the bob is the location for the punch-mark. If the bob does not remain over the same point throughout a complete revolution, the L's are turned on the nipples *N* and *N'* until it does. The principle involved is the same as adjusting the plate-levels of a transit—'revolve 180° in azimuth and correct one-half of the error.' Fig. 1 shows an ideal station in which the hole is 9 in. across at the top, 4 in. at the bottom, and 18 in. deep. These holes are best dug by means of a piece of  $\frac{7}{8}$ -in. drill steel, about 3½ ft. long, and sharpened to a point on one end and to a chisel edge on the other.

When putting in stations, cement, sand, and water can easily be carried about on a burro or horse, and the rock for the aggregate is usually close at hand. An ordinary old water pail is a good thing in which to mix the mortar. In

FIG. 2.

making the concrete for a station it is not best to try to mix the cement, sand and rock together, but to make the mortar separately and incorporate the rock in it while filling the hole. Of course, the concrete should be well rammed while being placed. In putting in a station, care should be taken to keep the  $\frac{3}{4}$ -in. station pipe vertical while the concrete is being placed. This is easy to do if the workmen do not get careless.

In setting up over the tringulation station, the plumb-bob of the transit is lowered into the  $\frac{3}{4}$ -in. station pipe until it has a clearance of about 1/16 in. all around. The  $\frac{3}{8}$ -in. pipes that are inserted in the stations are sufficiently large enough for all ordinary triangulation work, as they can easily be seen for a mile with the average transit. If longer sights are to be taken, or if it is necessary to elevate the station signal so that it can be seen over obstacles, a  $\frac{3}{4}$ -in. coupling can be screwed on the station pipe and a  $\frac{3}{4}$ -in. pipe, 20 or 30 ft. high, stiffened by suitable guying, can be used. A pipe larger than  $\frac{3}{4}$ -in. can also be employed by means of suitable bushings.

AMERICAN engineers are exploring the region surrounding Lake Maracaibo, Venezuela, for petroleum in behalf of an American concern. A Venezuelan citizen has also obtained a concession to develop the asphalt, petroleum, and mineral deposits of the Maracaibo and Bolivar districts, in the state of Zulia.

# Mineral Resources of the Kenai Peninsula

By W. M. BREWER

The known gold-bearing area of the Kenai peninsula, north of Seward and tributary to the Alaska Northern railway, comprises a zone about 70 miles long north and south and nearly 30 miles in width at its widest point, along the south shore of Turnagain arm. The earliest discoveries were made about 1896 in the neighborhood of Hope and Sunrise, two settlements on Turnagain arm. These discoveries were placer gold, and a little later, in 1898, placer gold was also discovered on Cooper creek, which empties into the Kenai river a short distance below the foot of Kenai lake.

In 1905 the first gold-bearing quartz discoveries were made in the mountains bordering on Falls creek, near the 26-mile post on the Alaska Northern railway. The next discoveries were made in 1908 in the Moose Pass district, to the north of Kenai lake. Later discoveries were made adjacent to the town of Seward, where outcrops are exposed along the shore line a short distance south of the townsite. These discoveries were followed by others made near the 4-mile station on the Alaska Northern railway, also near the 7-mile station, 18-mile station, 21-mile station, the 29-mile station, and northwest from the 34-mile station. Gold-bearing quartz was also discovered in the vicinity of Hope and Sunrise, to the west of the 71-mile station, as well as on the north side of Turnagain arm, near the head of Glacier creek, and near Bird point.

The country rock throughout this area is slate and gray-wacke with many intrusive dikes, composed of a much-altered quartzose material which up to the present time has not been classified. The orebodies are found in fissures, many of which have their lines of strike crossing the bedding planes of the country rock nearly at right angles. These fissures are apparently deep seated. Other instances occur where the fissures cross the bedding planes at various angles from 10° to 35° or 40°, and in some cases the orebodies occur lying conformably with the stratification of the slates, resembling gash veins.

The high gold content is one of the most noticeable features of the quartz in this district. This is not confined to any one type of orebodies, but is the rule rather than the exception, especially at and near the surface. The underground development has not yet been sufficient to afford evidence for what may be expected in depth. In the Kenai Alaska Gold Co.'s property on Falls creek, on the 100-ft. level, the ore averages \$60 per ton, while on the surface above practically the same result is obtained. These results are from the plates, mortar, and concentrate, and not from assay samples.

On the Primrose property, on Porcupine creek, which empties into an arm of Kenai lake opposite mile 18 on the Alaska Northern railway, ore taken from 70 ft. below the surface and up is reported to yield \$50 or \$60 per ton in a Little Giant mill. Mill-runs have also been made at the Skeen-Lechnor property on Falls creek with a 2-stamp triple-discharge Hendy mill which gave such satisfactory returns that a Milwaukee man who was visiting the district invested several thousand dollars in the property. Since then development work on a much larger scale has been started.

On Lost creek about 4 miles west from the 7-mile post on the Alaska Northern railway, a group of ten claims has been under development since September 1911, the capital being furnished by a syndicate of businessmen of Victoria, British Columbia. The underground development here totals 420 ft., while open-cuts and trenches totaling about 300 ft. have also been dug. Thirteen apparently distinct orebodies have so far been discovered, situated in a zone about 300 ft. wide and 7000 ft. long. The surface ores yield \$20 to \$500 per ton in free gold, while the underground workings indicate the probability of a lower

content over a considerable width in the mineralized zone, through which the rocks are very much sheared. The property has somewhat similar characteristics to the very extensive shear-zones in southeastern Alaska, such as the Treadwell and Perseverance groups. A 2-stamp triple-discharge Hendy mill would have been in operation on this property early in September, but the construction was delayed by bad weather. No returns from mill runs can, therefore, be given at present, although it is hoped and expected, because of the favorable situation of the property, that operations can be carried on during the entire winter. The owners have every reason to hope for good results at an early date.

On the property near the 4-mile post on the Alaska Northern railway development work is in progress, and it is planned to send a shipment of ore to the Tacoma smelter at an early date. This ore is reported to have about the same content as the general average of the surface ores in the district. On the beach near Seward considerable development work has been done during the past year, and the owners report satisfactory results. This ore, as well as that near mile 4, is more refractory than the ores usually found on the Kenai peninsula. The width of the various orebodies that have so far been developed is found to vary considerably, but where the high-grade ore is found the orebodies are usually about 12 to 30 in. wide.

The placer operations that have been carried on during the past season have been confined to Cooper creek, the Kenai river below the foot of Kenai lake, and on various creeks in the vicinity of Hope. The operations on all of these have been either by dredging or hydraulicking, and the reported outputs satisfactory. The fact that the company operating the dredge on the Kenai river has purchased quite extensive holdings on Cooper creek indicates that the dredging operations on the Kenai river have been successful.

The new Act of Congress relative to placer mining in Alaska, as interpreted by lawyers, puts a new value on the association ground located and held prior to the passage of the act, and it is considered highly probable that capital seeking investments of this character will be more active during next season than ever in the history of Alaska.

In the Moose Pass district, situated about 15 miles west of mile 29 on the Alaska Northern railway, operations have not been very active, although several properties, notably the group owned by John Gilpatrick between Summit and Slate creeks, bear all the earmarks of considerable value. But heretofore transportation from the railroad has been very unsatisfactory, and the cost for freighting by pack-trains almost prohibitive when added to the excessive charges for freight on the Alaska Northern railway. The cost of freighting from the railroad should in the future be merely nominal, as the Alaska Road Commission this past year has completed a wagon-road over which, it is reported, heavy loads can be hauled with ease. John Gilpatrick has been operating on his property with an arrastre during the past summer and has been cleaning up fair returns, considering the crude methods employed.

## Choking of Ore-Chutes

Choking in a chute underground is a frequent incident of work, and none of the methods commonly employed to start the ore running is completely satisfactory. A method satisfactorily employed at the Lord Nelson mine, in Victoria, Australia, was recently described by W. J. Nicol in the *Mining and Engineering Review*. A flexible pole of convenient length and cross-section is provided with a head made of pieces of hoop iron bent into a curve and nailed over the end of the pole. The curve of the hoop iron prevents the end of the pole from catching in the timbers of the chute. By connecting on successive lengths of pole this device can easily be thrust up a chute for long distances, and has been used to start a chute which had 'hung up' over 100 ft. above the level.

## The Moore-Butters Decision

In an appeal from the Circuit Court of the United States for the district of New Jersey, before George Gray, Joseph Buffington, and J. B. McPherson, circuit judges, in the United States Circuit Court of Appeals, for the Third circuit, October term, Joseph Buffington, circuit judge, handed down the following opinion in the case of *The Moore Filter Co. v. the Tonopah-Belmont Development Company*.

In the court below, The Moore Filter Co., the owner of patent No. 764,486, granted July 5, 1904, to George Moore for a filtering process, filed a bill charging the Tonopah-Belmont Development Co. with infringement thereof. On final hearing, that court, in pursuance of an opinion, reported in 195 Fed. Rep. 530, dismissed the bill on the ground that infringement was not shown. Thereupon the complainant took this appeal.

As applied in the present case, the patent concerns the process of filtering metal-bearing slimes and is known as the Moore process. The respondent's filter is for the filtration of like slimes and embodies the Butters process. Both processes utilize the cyanide ore treatment and the question before us is two-fold: first, does Moore's process involve invention; and, second, does the respondent's Butters filter make use of the Moore process. The cyanide ore process came into use about 1887 and is the real foundation of the tremendous increase of gold production in the last two decades. It is now the prevalent method of treatment. In it the ore is first crushed and then placed in tanks containing a solution of cyanide of potassium. This solution percolates through the crushed pulverized mass, and being a solvent of gold carries off such gold as is subjected to its action. This is called leaching, and any crushed ore through which percolation took place was termed leachable. For example, if the ore treated was of such a character that when crushed it was reduced merely to the condition of sand, then the recovery of its metal by the cyanide solution might be effected by two methods. In the first method the cyanide solution would be poured on a bed of sandy crushed ore and be allowed to percolate through it. In its passage the solution dissolved the metal and passed off as a clear liquid to zinc-boxes, or other well known means of reclaiming metals in solution. This very simple method was called leaching. The second was decantation, wherein the crushed sandy material after having been agitated in the cyanide solution was permitted to settle, so that the clear liquid containing the dissolved metal might be decanted. Thus so long as the crushed grain was so sand-like as to permit leaching, or would settle quickly and completely enough to permit decantation, reasonably satisfactory results were reached by the cyanide process with rich ores, but even with these the treated ore thrown on the dumps often contained large in the aggregate, though small per ton, unleached metals. This was due to the fact that the solvent had not and could not penetrate the coarse ground particles. If, however, the ore was crushed finer to permit the more intimate action of the solution a pasty mass called 'slime' was formed which was unleachable. The result of this was that great quantities of treated ore went to the dump-heap, and while laboratory filtration methods showed the presence and indeed the extraction of such metals, yet no one devised any commercial means or process by which this metal-laden dumpage or slime would be avoided or utilized. As a value-containing but unavailable feature these dumps occupied a relation to gold and silver mines like that of a slag pile to a blast-furnace or a culm bank to an anthracite mine. The proofs show the acute recognition of this grievous waste and the vain efforts of a great industry to avoid it. Thus, in *The Engineering and Mining Journal*, under date of October 8, 1892, in an article on 'The Cyanide Process in South Africa,' by Charles Butters and another, it is said:

Another difficulty frequently encountered in the application of the cyanide process in the treatment of 'battery

slime,' *i. e.*, the very finely divided material produced during the crushing, and which has a tendency to accumulate in pasty masses. These either resist the penetrating action of the cyanide or retain the dissolved gold during the leaching operation. No satisfactory method of breaking such material has yet been devised—the evil may be lessened by mixing the slimy tailing with clean coarse sand.

An editorial in the same journal, dated April 15, 1893, says:

After a certain amount of experience with any process, its weak points are seen and opportunities for improvements present themselves. To this rule the cyanide process is no exception. One of the great difficulties experienced in this process, or indeed in any lixiviation process, is the treatment of the slimes of an ore otherwise well suited to reduction by the method. They pack upon the filter, forming beds impermeable to the solution, and even if mixed with large quantities of coarser material are rarely attacked, *although laboratory experiments will show that their precious-metal contents are extremely soluble*. Of such material the Robinson Gold Mining Co., of South Africa, operating one of the largest cyanide plants on the Transvaal, has accumulated 60,000 tons, and the management has long despaired of treating it successfully, as the gold would not amalgamate nor would the cyanide permeate the mass if it were charged into vats. The average assay value was between \$7 and \$8 per ton, but the fineness, it is estimated, is such that it would pass a 225-mesh screen.

The same journal on August 11, 1894, contains an article on 'The Cyanide Process in the Transvaal Mines,' which says:

One of the great bugbears of the cyanide men on the Witwatersrand has been the treatment of slime, by which is meant the very fine, or in the case of free-milling ores the clayey portions of the tailing. Many suggestions have been made for the treatment of these, but the only really practical scheme so far appears to be to allow them to dry thoroughly and by screening or otherwise to reduce them to a fine powder. This powder is thoroughly mixed with sand tailing, and the mixtures will usually percolate fairly well.

In an editorial in the same journal, in speaking of the cyanide process, it is said:

Undoubtedly the process is well adapted to certain ores, but these appear to exist in but few localities and we have yet to learn how to extend the use of the process to more common material.

In an article on that process contributed by Virgoe to the same journal in 1894, he says:

Filter presses have been tried in South Africa, but without satisfactory results owing to their cost and the power required to work them. No mechanical means have yet been devised for the satisfactory separation of pulp and solution in the case of poor leaching ores. Such an invention would revolutionize the metallurgical world as far as the wet reduction of ore is concerned.

Commenting on this article a correspondent in September 1894, wrote the *Journal*:

Regarding the leaching properties of the ore or tailing to be treated, I am quite in accord with Mr. Virgoe, for badly percolating material (such as battery slime) is quite the greatest bugbear of the cyanide man.

The following year (1895) Charles Butters, writing to the *Journal*, said:

The treatment of slime is a question of importance, as at present there are many hundreds of thousands of tons of unleachable material lying useless on the hands of the various companies on the Witwatersrand.

And not only was the problem recognized and the need felt, but the agitation of it continued for years. In 1898, the same journal, after discussing the various efforts in the Transvaal to treat rejected slime, says:

Speaking generally, about 75% of the tailing from the Witwatersrand mills has been treated by cyanide in the usual practice, leaving about 25% to go into the slime-pit. There is therefore a large accumulation of this slime, besides that which comes from current working. What pro-

portion of the old heaps can be treated at a profit is yet to be ascertained; but it seems possible that an appreciable addition to the gold output may come from this source hereafter.

In the same year, referring to the Australian mines, the *Journal* says:

A great number of experiments are at present being conducted on the Kalgoorlie ores. Nearly all known processes, and several never before heard of, have their advocates. Of course some valuable knowledge will be gained by all this experimenting, and just as surely a great deal of very expensive machinery will in a short time be consigned to the scrap pile. \* \* \*

As yet the finer slime has not been successfully treated on a large scale, but some of the ingenious adaptations of the agitation or filter-press processes, now in the experimental stage, will undoubtedly solve the problem.

Indeed the whole matter was summed up four years later when in an article in the *Journal* of July 1902, on 'A New Treatment of the Slime Problem in Cyaniding Talcose Ores,' a writer, Stackpole, says:

Any metallurgist can appreciate the obstinacy of these sticky masses of mud, which, no matter how treated, would take almost a prohibitive length of time to percolate. Although experiments show that over 90% of the values in the clay is soluble, the ordinary methods only permit an extraction of 50 per cent.

The first suggestion for the solution of this world-wide problem is found in the *Journal* of December 5, 1903, being a communication from George Moore, wherein he described the process for which the patent in suit was issued to him the year following.

We deem a quotation from that article proper at this point not only as being in the line of historical sequence of the art, but for the further reason that our conclusion that Moore fully realized the scope of his invention and disclosed the same in his specification, is fortified by the fact that he had explained and disclosed it fully to the engineering world a year before his patent issued. In his article, after describing his process as installed at a certain mine and asserting that the advantages of his process were: "First, a saving of from 40 to 60c. per ton in labor; second, a saving of a like amount in extraction; third, a saving of over 50% in the cost of installation," he says:

The saving on extraction is due to the fact that, while the filter is in the slime-tank, and the suction in operation, an equalizing action is taking place, rendering all parts of the cake of equal resistance to the flow of solution and wash-water, so that, when placed in the washing tanks, a perfect displacement of solutions is accomplished. For example, we might consider that it would be possible for one spot on the 2880 sq. ft. of slime cake to have more of the coarser slime or fine sand than the other parts; then there would be less resistance to the flow at this point; therefore, the flow would be accelerated here, the slime would be brought up, and would cover this point more rapidly than the other parts until, by this increased coating, the resistance to the flow would become the same as at all other points. Thus, when lifted out from the slime compartment, the entire basket of filter is in condition for washing, and in practice, we extract all of the soluble gold.

After a careful study of Moore's patent, we have reached the conclusion that his process is a radical departure from the whole prior art and was an original and pioneer step in metal recovery by filtration. Like all important inventions its merit is its simplicity, and its novelty consists in his utilizing the simple elemental processes of nature. These processes he has, of course, neither discovered nor invented, but he has utilized them in combination in a manner never before used and has thereby secured a new result.

Briefly stated, the gist of Moore's instruction to the mining world was to filter an unleachable mass in such a manner as to cake the pasty slime so uniformly and evenly that the resistance of the slimy mass to percolation became uniform and even in every part of the cake. The result of such uniform and even cake-resistance was that when the cake was attacked by the percolating solvent its percolation was correspondingly uniform, and diffusive through the uniformly resisting cake. The solvent having by this uniform and even resistance been itself uniformly and

evenly percolated through the mass, it followed that when this percolated solvent was in turn subjected to a propulsive washing current, that such propulsive current, finding no path of least resistance in the uniformly-resisting cake or the uniformly-percolated solvent, moved forward uniformly and evenly to expel such uniformly distributed percolated solvent. The creation of this uniform and even resistance in the cake is the gist of Moore's process, and such uniformity, as we shall see, is secured by the slime being submerged when subjected to suction. The crux of Moore's process cannot be better or more tersely summarized than in his own words quoted above:

The saving on extraction is due to the fact that while the filter is in the slime-tank, and that means submergence, and the suction in operation, an equalizing action is taking place, rendering all parts of the cake of equal resistance to the flow of solution and wash-water, so that, when placed in the washing tanks, a perfect displacement of solutions is accomplished. For example, we might consider that it would be possible for one spot on the 2880 sq. ft. of slime cake to have more of the coarser slime or fine sand, than the other parts; then there would be less resistance to the flow at this point; therefore, the flow would be accelerated here, the slime would be brought up, and would cover this point more rapidly than the other parts until, by this increased coating, the resistance to the flow would become the same as at all other points. Thus, when lifted out from the slime compartment, the entire basket of filters is in condition for washing, and, in practice, we extract all of the soluble gold.

And this is only stating in other words what he set forth in his specification. Referring to the accompanying drawing the specification states:

In carrying out the process with the means disclosed in the accompanying drawings adapted particularly for use in connection with the slimes of precious metals, I introduce a solution to be filtered into a suitable tank, 1, in which I place a filtering device or means, 2, in the present instance made up of a series of filter-plates communicating with a common discharge tube, 3. A flexible or other suitable tube, 4, connects the tube 3 with any preferred form of hydraulic pump 5, and compressed-air pump 5a, and the filtering means 2 is permitted to remain within the tank 1 until the solid matter within the liquid being filtered has coated the walls of the filtering device to the desired thickness, say, for example, about  $\frac{3}{4}$  in. or more in most cases, but varying somewhat with the character of the slime which is being handled; and then the same is lifted as by pulley-and-cable mechanisms 6, out of and away from the tank, and the pump 5 stopped and pump 5a operated so as to apply air-pressure to the back of the canvas or to pass a current of air or cleansing current in an opposite direction to the movement of the liquid in the prior step, whereby the solid matter collected by the filtering device 2 will be discharged therefrom.

Applying this description to the illustration, it will be seen that the filter-leaves are completely submerged in a tank filled with fluid slime, and suction is then applied to the interior of the leaves. Applying suction to a filter completely submerged is to form an enveloping case or cake of a pasty nature in the filter. As the cake builds up it develops a thickness and compactness which gives the entire cake a capacity of uniform resistance to percolation. For so long as the resistance is not uniform the consequent increased rate of deposit at that point would set up and continue until the rate of flow there became equal to the rate of flow at all other points. The significance of this uniform resistance capacity of the cake, and that it was obtained by filter submergence, is stated in the specification where the patentee, in order to show that after the filtering process is completed an entire enveloping cake of uniform resistance capacity can be simultaneously discharged by compressed air, says that such action is owing to the process having produced an enveloping cake of uniform and even resistance capacity. His language is:

In order to effectively discharge the encrusted slime from the filter by the agency of compressed air, it is important that the slime be in the form of a compact layer of requisite resistance and of sufficient thickness, because otherwise when the air-pressure is applied portions only of the slime are blown off, thereby relieving or reducing the air-pressure and rendering it ineffective for the removal of the slime which remains and necessitating the use of other means—such as scrapers, brushes, and washing—for the complete

cleaning of the filter surface. This difficulty is wholly overcome in my process by immersing the filter into the tank containing the slime in suspension and depositing it in the manner described, the effect of which is to automatically deposit the slime in a homogeneous layer, as will be readily understood. Hence, when the slime has been thus deposited to the requisite thickness the compressed air does not blow holes in the layer of slime and only partly clean the filter, but it strips off the entire layer of slime and effectively cleans the filter without the use of auxiliary cleansing mechanism.

Indeed of the fact that the result of subjecting a submerged filter to suction is an enveloping cake of uniform and even resistance, there can be no doubt under the proofs in the case. To question it is to dispute the operation of the laws of nature. In his 'Cyaniding Gold and Silver Ores' (edition of 1907), H. F. Julian, who was called as an expert by respondent, and nowhere questions his prior statement, in describing the advantages of submerged-leaf filters subjected to interior suction, says:

One of the chief characteristics of this class of filters is that during the formation of the cake, if the resistance to percolation should vary at any point over the filter surface, an adjustment immediately sets in, owing to the parts of greatest permeability taking on the deposit quickest. This increases the resistance at those points until it brings the rate of percolation equal all over the cake. Washing out the dissolved metals is then done uniformly.

And in his testimony C. F. Chandler, the distinguished scientist and expert for respondent, says:

Uniformity of resistance of the cake is the natural result of the laws of filtration. Increasing thickness of cake at any one point greatly reduces rapidity of filtration at that point and thus equalizes the thickness of the cake. When the thickness of the cake reaches a point at which filtration becomes very slow, the continuance of filtration at one part a little longer than at another part will not make any material difference in thickness; even doubling the time of filtration would have little effect if filtration is carried to the point of nearly maximum thickness and resistance, a condition which the Moore patent seems to indicate is desirable.

In view of these well understood natural laws of filtration and of the subject matter of the specification and the application of the process as illustrated by description and drawings, there can be no question that, to those skilled in the art, the cake of uniform and even resistance produced by Moore's process is aptly described by him in his specification as "immersing the filter into the tank containing the slime in suspension and depositing it in the manner described, the effect of which is to automatically deposit the slime in a homogeneous layer, as will be readily understood."

The specification in the language following:

However, this cleaning step of the process need not be taken until an intermediate auxiliary step has been performed, which consists in introducing the element 2, after having been coated with the solids, into a tank 7 of water, the drawing or sucking operation of pump 5 being continued while the element 2 is being subjected to the said water-bath. When this step is employed, the next succeeding is the operation just described. It will be obvious that the water bath may be employed or not, as described, the same being preferable when the filter is used for filtering precious ores, the said step tending to wash out the remaining metal held in solution or solvent thereof within the solids coating the filtering device.

discloses an optional additional step in the process, which step is made an element in the claims herein in controversy. The proofs show that in this step important results are obtained in that substantial quantities of the gold-carrying cyanide solution still remaining in the cake are recovered and that this recovery is due to the uniform and even resistance capacity conferred on the cake by the disclosed process.

It is contended, however, that the Moore patent is invalid by reason of the disclosures of the prior art. But in our view this contention is based on a failure to recognize the true significance of what Moore really did. Practically his problem was to make commercially possible the recovery of a minute amount of valuable metal from a large quantity of mud. Of the fact of the metal being there, there was

no doubt, for that fact, and indeed that it was possible to extract it, the tedious and costly method of laboratory filtration showed. It suffices to say that no one of the numerous patents cited did such work, used such process, or effected such results, and if none of them led their inventors or users to the use of any process whereby such work could be done, or even led to a suggestion in their descriptive matter of the possibility of the use of any such process as Moore's, it follows they taught Moore no more than others. So far as the patent here in question is involved, Moore's disclosure was the process he originated and not the machine with which he illustrated the use of his process in accordance with the statutory requirements that he file a written description "of the manner and process \* \* \* of using it." To find, therefore, here and there in prior patents, and disassociated from each other, all the mechanical appliances of the combination apparatus which Moore thus illustratively used is not to prove that Moore's process is not original.

Viewed from a patent standpoint, the significance of a machine lies not in its form but in the principle on which it works, as will be seen in the requirements of 4888, "in the case of a machine, he shall explain the principal thereof." It suffices therefore to say that very few of these patents are even for a process, and as none of them operated on the principle or process of Moore, they cannot be held to forestall or minimize the originality of Moore's subsequent disclosure. And in giving these patents their due relation to Moore's disclosure the fact must not be overlooked that the slime problem which Moore solved only came into existence from the use of the cyanide process, which began, as we have seen, about 1887. It will therefore be manifest that no patents preceding that date and none subsequent thereto which did not apply to the cyanide process, were calculated to solve the cyanide percolating difficulties, that arose in the use of that process. So also, to say that following prior laboratory practice, it was possible to leach and extract the unrecovered ore left in a pasty mass by the cyanide process is not to destroy Moore's patent; for this is to lose sight of the practical working value of Moore's process as a workable economic treatment, as compared with theoretical possibility of laboratory practice. By repeated dilution the laboratory could and, we will assume, did recover with practical completeness all such unrecovered metal, but this has been done with an expenditure of time, labor, and expense out of all proportion to the value of the metal. When therefore Moore disclosed a process by which such recovery was made enormously profitable and by which he turned a dump heap which under all known processes, machines, and laboratory methods was worthless into profitable ore, we are constrained to give little weight to the suggestion that his process was either anticipated, a mere advance incident to the art, or involved no invention.

So, also, it is said that the step described in his claim, viz.: "further impoverishing the solids by a cleansing operation," was merely the washing or dilution of the prior art. Considered in its literalism and in isolation, such contention may seem plausible, but considered as a step in Moore's process it takes on new significance and value. Bearing in mind that in the prior steps of the process covered by this claim, the completely submerged filtering medium has formed a cake of uniform resistance at all points and by reason of such uniformity the solvent has percolated and is permeating the cake, it follows that the step which follows is a non-diluting and bodily displacement of the solvent and not a diluting intermingling. This displacement in contrast with dilution, not only saves the time and expense of repeated dilution and refilling, but also obviates excessive dilution of the solvent solution and the necessity of rehandling large volumes of diluted solutions in the recovery of the metal. It seems, therefore, that the "further impoverishing the solids by a cleansing operation" of Moore's process, owing to the prior step whereby a cake of even and uniform resistance is secured by submergence, is not a mere washing or diluting step, but is one wherein there is exerted a uniform pressure or pushing action

through the entire cake surface, thereby in effect advancing a wall of water pressure to force ahead of it from the cake the value-bearing solvent liquid and leave in the cake an equal volume of non-value-bearing water. This final result is secured by first having built up a cake of uniform resistance to solvent fluid flow, and, secondly, by again submerging the filtering medium and its built-up cake in the non-value-bearing displacing fluid. By this displacement by pressure difference only Moore pushes ahead instead of washes through the cake a contained-metal-carrying fluid. As showing the practically complete metal extraction by the Moore process, we restrict ourselves to the uncontradicted testimony of results at a South Dakota mine, where the original slime contained gold at the rate of \$7.90 per ton of dry slime. After filtration alone the cake still contained \$2.75 per ton of dry slime. After being then subjected to the displacement step there was left in the cake but 4c. of gold per ton of dry slime.

Being of opinion, therefore, that Moore's process was novel, useful, and inventive in character, his patent is valid, and we next turn to the question of infringement.

As claims 4 and 5 furnish sufficient basis for deciding that question, so far as the respondent's device is concerned, and as some questions, not necessary to be here decided, exist as to claim 10, we restrict ourselves to a consideration of claims 4 and 5. In considering the question of the infringement of a process patent, it must be borne in mind that the monopoly secured by the claims is, generally speaking, a monopoly of the process, and the test of infringement is whether such process is utilized by the infringer. As the apparatus shown in a process patent is only to show that the process may be practically applied, it follows that such illustrative apparatus does not limit the process patentee to that type of machine alone. If that were the case a process patent would be of little value. So distinctive and separate in the patent law are process and apparatus for utilizing such process that where, after a patent for a process by one inventor a second inventor might patent a novel apparatus for utilizing the process, the situation would arise that the inventor of the process could not employ his process in such machine without license from the machine patentee and the latter could not use the process in his machine without license from the process patentee. It will therefore be evident that the test of process infringement is not the similarity of apparatus, but rather whether the apparatus, no matter what its form, utilizes the process. Tested by this standard, it is clear to us the respondent's device infringes. In form the particular apparatus shown in Moore's patent and the apparatus of respondent vary in the number of tanks, in the differences between changing the fluid which envelops the filtering medium, as in respondent's device by allowing the filtering medium to remain stationary in one tank while the submerging fluid is first drawn off and the second submerging bath is then drawn into the same tank, while in Moore's the filtering medium is raised from the submerging bath in the first tank and then lowered into the second submerging bath in a second tank. But this difference in numbers of tanks and of respective withdrawal and replacing of different baths in no way affects the identity of the process, for it is manifest that Moore could in his patent specification have shown the use of his process, just as well by using respondent's apparatus, had he known of it, as his own. Both alike use the principle of submergence and intra-leaf suction to create the uniform and even resistance of the cake and both alike use the principle of intra-leaf pressure, Moore using air and the respondent water, to shed the uniformly resisting cake from the filter. For the mere fact of the output being carried off as a dry product in Moore's case to a dump heap and in respondent's in fluid form to a slime pit, does not go to the substance of the process. In the essentials that involve the invention the two are alike. Had an apparatus such as respondent's, been in use prior to Moore's there would have been no invention either in the process or in the apparatus shown in Moore's patent. And what, if preceding a patent, would have anticipated it, equally infringes if

subsequent. We therefore hold the fourth claim is infringed.

As we are of opinion and so find from the proofs that there is in respondent's device a "removing the medium while continuing the drawing action," the fifth claim is also infringed.

The decree of the court below is therefore reversed and the cause remitted with instruction to enter a decree adjudging claims 4 and 5 valid and infringed and for such action by that court in the way of injunction and accounting as it shall deem fitting.

## Low-Grade Ore Treatment at Kalgoorlie

Some remarkable work is being done at Kalgoorlie among the low-grade mines, situated mostly about three miles from the 'Golden Mile,' and the following details of the August output of the Golden Dream mine will be of interest. Mining is both in open-cuts and underground, at about 150-ft. depth; hoisting is by friction hoist driven by motor; small jaw-crushers are used; the Huntington mill is driven by gas-engine, as is also other machinery. The sand is cyanided in small vats of about 30-ton capacity, and the slime is stored in ponds for future treatment.

Treated during August, tons.....	1602
Yield from amalgamation and cyanide plant.....	\$2810
Yield per ton .....	1.76
Cost: .....	Per ton.
Water .....	\$0.25
Electric power and lighting .....	0.04
Suction-gas power .....	0.05
• Cyanide treatment .....	0.10
Wages .....	0.98
Manager and secretary .....	0.05
Bullion charges .....	0.03
Stores and sundries .....	0.17
Total cost per ton .....	\$1.67
Less Government subsidy for low-grade mines...	0.10
Net cost per ton .....	\$1.57
Profit per ton .....	0.19

## Manganese Production in Russia

The renewed activity of the iron industry in Russia, especially noticeable in the southern districts, has exercised a favorable influence on the production of manganese ore, which is principally found in the South Russian district of Nikopol. During the first half of this year the aggregate production of manganese ore in Russia, according to the *Kölnische Zeitung*, amounted to 6,724,000 poods, an advance of 1,642,000 poods, or 32.3% as compared with the corresponding period of 1911. The annual output of the Nikopol manganese mines is estimated at 17,500,000 poods. For the first six months of this year 7,288,500 poods, or 1,878,000 poods more than in the corresponding period of 1911, were shipped, of which quantity 1,564,660 poods—being, however, 390,200 poods less than last year—were destined for abroad. Taking the first eight months of the current year, the export of manganese ore from the Caucasus amounted to 38,669,416 poods, as against 30,880,990 poods for the corresponding period of 1911 and 33,909,685 poods in the course of the first eight months of 1910. The principal export countries are Great Britain, Belgium, Holland (for Germany), America, Germany, Austria-Hungary, and France. During the first half of the present year the rates for manganese ore were well maintained, the first reduction being registered in the month of July, when the average price for the first half-year of 6 to 7 kopeks, as against 4½ to 5½ kopeks for the corresponding period of 1911, and 5 to 6 kopeks two years ago, was reduced to 5½ to 6 kopeks.

Nome Customs Report

The following statement of commercial business at the port of Nome during the navigation season of 1912 was made public by R. W. J. Reed, deputy collector, October 31.

Arrivals of vessels:	
From United States ports .....	36
From foreign ports .....	29
Passengers arrived:	
From States at Nome.....	1,603
From St. Michael .....	440
General merchandise received, tons .....	26,231
Coal received:	
Domestic, tons .....	1,978
Foreign, tons .....	14,427
Total coal received, tons .....	16,405
Lumber received, feet b.m.....	1,747,775
Live stock received, head .....	125
Sailings of vessels:	
For United States ports .....	30
For foreign ports .....	32
Passengers outward:	
Ocean vessels, from Nome .....	1,913
Ocean vessels, from St. Michael .....	1,452
General merchandise shipped, tons .....	704
Placer tin shipped, tons .....	129
Placer tin mined in this vicinity, tons.....	173
Gold dust and bullion shipped:	

	Ounces.	Value.
Custom House .....	144,981.31	\$2,656,661.94
Post Office .....	15,098.38	274,816.32
Totals .....	160,079.69	\$2,931,478.26

It is estimated by engineers in the district that the total gold output for the season will probably be increased \$100,000 by dredges operating in November.

A Convenient Telescoping Burner

By FRITZ FRIEDRICH

In regulating the supply of heat to an apparatus by means of a gas burner, two methods may be employed, either the height of the flame may be changed by opening or closing the gas and air supply, or the distance be-

TELESCOPING BURNER.

tween apparatus and burner may be suitably adjusted. The first of these methods is applicable only within narrow limits, because of the striking back of the burner. Recourse is therefore had in general to the method of

regulating the distance of the burner from the apparatus by the use of wooden blocks or of some other support for the burner, since the raising or lowering of the entire apparatus is usually difficult, if not impossible. One burner of adjustable height has been recently constructed, in which metal tubes of different length are screwed to the base of the burner. This method possesses the disadvantage (1) that the burner may be adjusted only to the heights corresponding to the length of the tubes, and (2) that a change of the adjustment is not possible without shutting off the flame.

These disadvantages may be most satisfactorily avoided by telescoping the tube of the burner as shown in the accompanying sketch. By means of this apparatus it is possible to regulate the height of the burner from the usual size up to 25 cm. with a single, or up to 30 cm. with a double telescope tube. In the great majority of cases the single or the double telescope tube will suffice. There is, however, theoretically, at least, no limit to the number of tubes used. Since the end of the uppermost tube is tapered to the original diameter of the burner, there is no danger of the flame striking back.—*Jour. Amer. Chem. Society.*

Automatic Pump Starter

A simple arrangement is used at the Giroux Consolidated Mines Co., at Kimberly, Nevada, for automatically governing the steam-driven pump which forces the water from the compressor overflow tank for cooling water to a cooler and storage-tank situated on the hill above the works. This operation allows the water to be used over and over again. A small tank near the compressor receives the cooling-water from the jackets. A hollow metal

AUTOMATIC PUMP STARTER.

ball floats on the water in the tank and is attached by rod and lever connections to the valve in the inlet steam line to the pump. As the water rises in the tank the steam is gradually turned on and operates the pump. As the water recedes in the tank the steam is shut off and the pump is stopped.

TARANAKI, New Zealand, has been noted for many years for the large quantities of black sand, consisting largely of magnetite, on its beaches. Like the oil industry, there have been many attempts to treat this mineral, but with little success. The sand contains from 56 to 70% of metallic iron, titanium 1.5 to 9%, and low percentages of sulphur and phosphorus. A blast-furnace worked satisfactorily near Auckland for a time in 1892, but repeated efforts since have not been marked by success. Briquetting has been tried, producing a fair quality of iron. The whole question must be systematically investigated before capital can be interested.

## Discussion

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment. Insertion of any contribution is determined by its probable interest to the readers of this journal.

### Persistence of Ore in Depth

The Editor:

Sir—In T. A. Rickard's article, 'Persistence of Ore in Dept,' appearing in your issue of August 31, there is an error, the vertical depth of the Ooregum mine, Kolar goldfield, being given as 2420 ft. The vertical depth of the present deepest level in this mine is 4240 ft. below the surface.

T. PRYOR.

Oorgaum, India, October 9.

### Mexican Conditions

The Editor:

Sir—Not long since at the annual meeting of a company operating one of the large dividend-paying mines of Mexico, the manager stated that conditions generally were worse than at any previous time, the reasons being the general apathy and the sympathy between the Federal and rebel soldiers. His company had been 'held up' for \$50,000. He said, further, that there was a mutual understanding between the English, German, and French companies operating in Mexico, that they would compile in authentic shape all claims for damage, robbery, and murder committed by both Federals and rebels, and would demand payment from the United States Government, because, in accordance with the Monroe Doctrine, the United States Government had not permitted those countries to interfere. If such claims be taken before The Hague tribunal, we seem likely to have to pay them.

When one considers that in every English, German, or French colony in the world life and property of foreigners is safe, that under the Monroe Doctrine the United States will not allow foreign interference by any European government on the Western hemisphere, that most of them has suffered frequently from revolutions, while our Government has done little or nothing to safeguard the peace, is it to be wondered that other nations demand that we foot the bills? The Monroe Doctrine has only retarded the development of the whole of Central and South America. Is it not time that we get off the fence, pursue an active course, and make all of the Western hemisphere safe and secure for everyone to transact business and live in safety, wherever one likes?

G. L. SHELDON.

Ely, Nevada, November 4.

### Utilization of Power

The Editor:

Sir—In the editorial on utilization of power in your issue of November 9, it is said that the cost of construction and the difficulties of operation of the gas-producer upon a small scale render it unavailable for plants of small or moderate size, though highly efficient in large installations. This hardly states the case quite correctly, because the maximum limit is very soon reached. The largest producer plant in the world is in this city, and is a failure solely on account of its size. I have been advised by leading makers of producer-gas engines that 1000 hp. is as large as is practicable to use. The destructive effect of suddenly applied strains is well known, as seen in the water-hammer jar caused by quickly closed valves, and each stroke of the gas-engine is the result of an explosion.

Steam-turbine electric generators of more than 5000 hp. are quite common, and are required for the economical operation of power-plants. In the article on 'Power at the Waihi Mine' the comparative cost of water-power must not

be taken literally, as the rate stated would just about pay the wages of a single attendant, although it might perhaps be claimed that such a water-wheel needs no attendant. Hydro-electric plants generally need steam or gas auxiliary generators to tide over peak loads. These have the advantage of not using fuel when the power is not needed, while the water that is not used at once is generally lost, so that in some cases it has even been found better to revert entirely to the fuel generator.

R. B. SYMINGTON.

San Francisco, November 15.

[The cost of water-power at Waihi is so astonishingly low that it will be worth while to give the detailed figures from a report of the company, December 31, 1911.]

### COST OF DEVELOPING 558 BRAKE-HORSE-POWER, WAIHI

	£	s.	d.
Wages .....	433	6	11
Oil and lubricants.....	19	10	6
General supplies .....	66	3	5
Foundry .....	10	9	3
Total cost for year.....	529	10	1

This is at the rate of \$4.56 per horse-power-year, as given by Mr. von Bernewitz. This does not include maintenance of ditches, flumes, and dams, however, this item being grouped with other repairs to plant, buildings, and machinery in the 'revenue account,' characteristic of English methods of book-keeping. Neither does it include interest and depreciation, which are also given separately. These considerations equally apply to the costs given for steam and gas-engine power, all three appear slightly lower than they actually are in fact.—EDITOR.]

### Ore Reserve and Life Extension

The Editor:

Sir—I have read the article entitled 'Ore Reserves and Life Extension,' by Morton Webber, published in the *Mining and Scientific Press* of October 19. To the first part of this article no exception can be made, as it is apparently original. The latter part, however, commencing near the bottom of page 494, is for the most part a direct copy, with some slight alterations in the wording, of extracts from the best chapters in H. C. Hoovers' 'Principles of Mining.' Read on this page the five geological heads under which life extension should be considered and compare them with the five factors in 'Principles of Mining,' page 23. Also on page 27 of 'Principles of Mining,' the second paragraph states: "No engineer is properly equipped to give judgment on extension in depth without a thorough grasp of the great principles laid down by Van Hise, Emmons, Lindgren, Weed, and others." Mr. Webber in his article, in which no reference is made to Mr. Hoover's book, writes in the paragraph preceding the five geologic heads: "They are so important that no valuing engineer is properly equipped to deliver judgment on the life extension of a mine without a thorough grasp of the underlying principles laid down by Lindgren, Emmons, and Van Hise."

The rest of the article is mainly a somewhat embellished and decorated rehash of Hoover's best points, with Hoover's style poorly disguised, and in some places not disguised at all, which anyone can see by reading carefully chapters III, IV, V, and VI, in 'Principles of Mining' and then reading Mr. Webber's article. I will make one more quotation from Hoover's book, which states at the end of chapter VI, in the general summary, that "The wise engineer will put before his clients the scale, the weights, and the conclusions arrived at. The shrewd investor will require to know these of his adviser." Mr. Webber closes his article by saying: "The able engineer who has profited by experience will place these facts unreservedly before his employer. The serious minded operator will require them of his engineer."

I think it only right that this should be brought to the

attention of your readers, as I know it is not the custom of your paper to publish such flagrant plagiarism from a well known book with no reference made to either the book or author.

D. C. LIVINGSTON.

Moscow, Idaho, October 24.

The Editor:

Sir—I have read the letter of D. C. Livingston relating to my article, 'Ore Reserves and Life Extension.' Some four years ago I was managing a mine in Central America with no other companions but the millman, a mine accountant, and H. C. Hoover's book. The latter I read from beginning to end several times. I have not seen it since, although I am perfectly willing to concede that much of the more important chapters were firmly impressed in my memory. I am also glad to say that the principles gathered therein have helped me in applying my college training to practical ends.

I have since read much of the works of Lindgren, Emmons, and Van Hise, and it is to these writers that I am largely indebted in the more geological part of my article, and not to Mr. Hoover, who is just as much indebted to them as I. I have borrowed Mr. Hoover's book and quote from the preface:

"The bulk of the material presented is the common heritage of the profession, and if anyone may think there is insufficient reference to previous writers, let him endeavor to find to whom the origin of our methods should be credited. The science has grown by small contributions of experience since, or before, those unnamed Egyptian engineers, whose works prove their knowledge of many fundamentals of mine engineering, six thousand eight hundred years ago. If I have contributed one sentence to the accumulated knowledge of a thousand generations of engineers, or have thrown one new ray of light on the work, I shall have done my share. I therefore must acknowledge my obligation to all those who have gone before. \* \* \*

*This expresses my own feelings exactly.*

Regarding the similarity in phraseology, I have to say that there are similar likenesses between some parts of my article and the recent contribution by T. A. Rickard, 'Persistence of Ore in Depth,' and the discussion thereupon. My article was submitted for publication last August, before Mr. Rickard's contribution appeared in print. As Mr. Livingston appears to have a fair amount of time on his hands, he might use up some of his energy along the lines of finding some connection here. I also wrote an article for the *Mining and Scientific Press* entitled 'Conservation of Capital in Gold Mines,' to which you referred editorially, as I remember it, as "novel and original." Here is another field for Mr. Livingston. After that he can again apply himself to connecting up an article by me entitled 'Unavoidable Errors in Mine Sampling'; for Mr. Hoover has written something on that subject also.

I am at the present time working on an article on economic speed in the removal of orebodies. Mr. Hoover has written something similar in his book. Does Mr. Livingston therefore maintain that where my conclusions agree with those of Mr. Hoover, I must accord all honor to him or choose another subject? In 'Ore Reserves and Life Extension' I referred to the change in the nature of ore with depth in certain mines. I quoted the Mount Morgan gold mine, Queensland, and also referred to the changes in depth at Butte and Leadville. On referring to page 26 of Mr. Hoover's book I find that he has mentioned identical examples. It would appear from Mr. Livingston's reasoning that I have again been encroaching on Mr. Hoover's preserves.

It is interesting in this connection to quote two extracts from my article 'Ore Reserves and Life Extension' and two extracts from a contribution by H. C. Hoover to *The Mining Magazine* of London entitled 'Mine Valuation and Mine Finance.' My article was published in San Francisco on October 19, and the contribution by Mr. Hoover was published in London on October 15. My article was submitted for publication during last August. I did not see

Mr. Hoover's article before publication, and I judge that it is equally certain that he did not see mine. Notwithstanding these facts, the two articles show striking similarities.

For example, in my article I write: "the relative magnitude of the ore reserves in any particular mine is largely a matter of administrative policy." Mr. Hoover writes: "The quantity of ore that may be proved is largely the result of managerial policy." Again I write: "Such a method of valuation disregards the primary basis on which the appraisal of life extension should rest, namely, geological evidence. It disregards the widely varying geologic nature of two different mines, and it ignores the important collateral evidence supplied by adjacent properties." Mr. Hoover writes: "Further, any such basis of valuation fails to take into account the widely-varying geologic character of mines; it disregards any collateral evidence such as that of continuity from neighboring mines of the general experience in the district."

For my part, any engineer is entitled to what I have written. I believe that there is little truly original in either contribution, as the facts are more or less the common property of the profession. I merely draw attention to these similarities as Mr. Livingston has quoted likenesses between certain passages in my article with those of Mr. Hoover's former work. It is a poor rule that will not work both ways. For the benefit of Mr. Livingston: this proverb is not original with me.

MORTON WEBBER.

New York, November 11.

## Canada and the Nickel Supply

The official reports of mineral production in Ontario show that in 1910, the latest year for which such figures are available, there was hoisted from the nickel-copper mines of Sudbury 652,392 tons of ore, of which 628,947 tons was smelted in the blast-furnaces and put through the converters. The product was 35,033 long tons of matte, 23.6 tons of ore being thus required on an average for one ton of matte. In this quantity of matte there was contained 18,636 tons of nickel. The production of 1910 was much the largest since the nickel mines of Sudbury were opened, a quarter of a century ago, and this field is the most important source of nickel in the world. The value of the nickel contents of the matte, on the basis of what it is worth—or estimated by the producers to be worth—at the point of production was \$4,005,961. To the output of the Sudbury mines must be added, for the sake of completeness, the nickel content of the silver ore mined at Cobalt, estimated to amount to 504 tons, bringing the total yield of nickel in 1910 up to 19,140 tons. The use of nickel for coinage purposes is spreading. In 1909 the Government of Turkey was authorized to put out an issue of coins made of nickel or aluminum. The latter metal, upon being tested, not having given satisfactory results, nickel was decided upon, and it has been resolved to issue 120 millions of 5-para pieces, 120 millions of 10 paras, 70 millions of 20 paras, and 20 millions of 40 paras; in all, 330 millions of pieces. The money is all to be coined in 4 years and issued in 20. The only other important source of nickel is the island of New Caledonia, whose output, however, in proportion to the whole, is now much less than that of Sudbury. Société le Nickel, whose production is from New Caledonia ores, operates refineries in France, England, and Germany. From 1900 to 1909 the French production fell from 1700 to 1200 tons, while that in England rose from 1500 to 2800 tons, and in Germany from 1400 to 3100 tons. Thus in 1909 the total output of nickel from New Caledonia was 7100 tons.—*Monetary Times*.

EXPORTS from Tampico to the United States during the quarter ended September 30, 1912, totaled \$1,198,597, of which crude oil constituted \$1,125,148. The declared exports in the same quarter last year aggregated only \$174,648.

## Special Correspondence

### NEW YORK

THE METAL MARKET.—THE SHATTUCK-ARIZONA.—HOPES FOR THE REA.

So far as the mining markets are concerned, the unsettled condition created by the presidential election, coupled with the war crisis in southeastern Europe, still remains. The copper-metal market is dull, and owing to the prices being 'pegged' the Producers' report was without its normal effect. The increase of 13,000,000 lb. connected with the record-breaking delivery of 84,104,734 lb. to domestic consumers might ordinarily be expected to produce some marked recessions. The October output was 145,405,543 lb., within about 200,000 lb. of the record production of last August. The war situation has been the underlying factor in the metal market for a good many months. A year or more ago, when the copper surplus was in process of disappearance, the real explanation was the large purchases abroad for ordnance purposes, and at the present time the real factor in metal is this element of consumption and how far stocks held for this purpose must be and will be replenished. During the past week buying for export in New York is reported to have been mostly at a standstill. Domestic consumers are said to be buying for immediate needs only, and there is no tendency to build up stock piles at 17 $\frac{3}{4}$ c. per pound.

The rejuvenation of Granby is looked upon as an accomplished fact. The stock has advanced to 75, the best price at which it has sold since the slump, which ensued after the report made by Otto Sussmann, in which he said the available ores of the Granby were almost exhausted. The Granby's financing of the Hidden Creek property out of its earnings, instead of making an issue of convertible bonds, is a healthy movement toward conservatism in mining finance, and should commend itself to the general public. The deal for the control of the Shattuck-Arizona is apparently in stays. The latest rumor is that the property is to be taken over by the Calumet & Arizona. It is easily to be recognized that the Calumet & Arizona is really the logical purchaser, and could probably handle the property to better advantage than any other. Shipments have just been started from the Shattuck-Arizona to the Calumet & Arizona smelter under a new contract, which provides for a minimum production of 500 tons daily after next July. Louis Hill, of the Great Northern railway, is the largest owner in the Shattuck-Arizona, and it is said that the new deal is to be made on a basis of exchange of shares, two shares of Shattuck to be given for one share of Calumet & Arizona.

The La Grange Mining Co., operating very large placer properties in Trinity county, California, has re-elected its old board of directors, consisting of D. M. Riordan, Roberts Walker, former chairman of the board of the Rock Island railway, and W. H. Jones. The Lightning Creek Gold Gravels & Drainage Co., Ltd., and the Chesterfield Copper Co. have both been listed on the New York Curb. The former is placer property in the Kootenai district, while the Chesterfield Copper Co. property is in Pima county, Arizona, and is offered by Philadelphia people. Harking back for a moment to the process of fine-tooth-combing of the globe for new mineral deposits, it is worthy of note that the Yukon Gold Co. is said to be about to emulate the example of the Oroville Dredging Co. and is now looking for a dredging property in South America. Engineers' reports have been examined, but no negotiations have as yet been concluded.

The Rea Consolidated Gold Mines of Porcupine, a property in which John T. Milliken, of St. Louis, was interested, was at one time considered one of the most promising properties in Porcupine, and its later collapse was one of the severe blows from which the district suffered. Mr. Milliken and his associates made some very strong efforts to interest the Consolidated Gold Fields of South Africa in their mining ventures. The Golden Cycle mine

and mill was at one time reported to have been sold to the English company, and later this company was reported to have purchased a large interest in the Rea in Porcupine. Neither deal was ever brought to a successful conclusion. The refinancing of the Rea is reported to have been concluded, and it is to be hoped that the report is correct. The reopening of the mine will do much to bring back confidence in Porcupine, and if present plans as to the erection of a 10-stamp mill can be carried through, it will restore hope to many holders of the stock who purchased at high prices, and have been forced to carry their holdings down to a point where there was absolutely no price recorded for them. What new interests, if any, have been brought into the company, has not as yet been disclosed. The McKinley-Darragh company, of Cobalt, has just declared its regular quarterly dividend of 3% and an extra dividend of 17%, this being an increase in the extra distribution of 10% and making a total of 50% declared this year. Some of the New York people with connections in Butte report that speculation in mining properties in and around that city is as feverishly active as any previous movement, and Butte has had many booms.

The El Oro Mining & Railway Co., Ltd., under the management of the Exploration Co., Ltd., of London, returns for the months of October are: mill ran 30 days; treated 21,090 tons of ore and 15,920 tons of tailing, yielding bullion \$170,990; working expenses, \$91,170; expenditure on development, \$25,490; total expenditures, \$116,660; profit, \$54,330; railway profit, \$9070; total profit, \$63,400. Expenditures on permanent mine improvement were \$6650. The Tomboy Gold Mines Co., Ltd., under the management of the Exploration Co., Ltd., of London, reports for October that the mill ran 29 days and crushed 11,000 tons of ore yielding bullion valued at \$45,000; concentrate shipped, \$41,000; total, \$86,000; expenses, \$46,000; profit, \$40,000; expenditure on permanent improvement amounted to \$11,752.

### BOSTON

NEW BIG MINE IN CHILE.—RISE OF BURRAGE.—SPLIT IN THE COLE-RYAN SYNDICATE.

Chile is to have another big copper mine, in which the Guggenheims are interested. That noted family has joined Albert C. Burrage, the Boston copper man, in his enterprise at Chuquicamata, on the plateau 100 miles east of the port of Antofagasta. The property is 9500 ft. above sea-level. The Chuquicamata mines are particularly fortunate in having railway connections through a 6-mile branch from the main line of the Antofagasta & Bolivia railway. Some time ago Mr. Burrage, who has not been very active on the surface in copper affairs, and who is not at all communicative, allowed himself to be interviewed in London, in which he gave a hint of his interest in copper properties, particularly in South America. The new property is to be held by a close corporation called the Chile Exploration Co., owned and officered by the firm of M. Guggenheim's Sons and Mr. Burrage. Daniel Guggenheim will be president and Mr. Burrage the vice-president. It is announced that neither the American Smelting & Refining Co. nor the Guggenheim Exploration Co. is in any way interested in the new enterprise, and no public or private flotation of the company will be made. The property is suited to steam-shovel mining, but the ores require a new method of treatment, being unsuited to direct smelting and are especially adapted to leaching. Native miners have worked the properties in a crude way for the past generation, and they have been known quite well to mining engineers and metallurgists on account of the peculiarities of the ore, there having been considerable discussion as to how it should be treated. Another difficulty is that the deposit is situated in a desert 50 miles from any water supply. Because of the small scattered units of Chilean ownership it was impossible to raise money for piping an adequate supply of water across the desert from the mountains to the mines. Mr. Burrage optioned these properties in London two years ago, and since that time has been acquiring millsites, lime-

stone and native sulphur deposits, also a concession to take fresh water from the San Pedro river and all available water-power rights on the Loa river, 20 miles away, amounting to 30,000 hp. Mr. Burrage is a picturesque character. Going back to the days when J. Edward Addicks, of the Bay State Gas Co. and allied gas companies of Boston, controlled the gas situation of this city, and Henry H. Rogers was trying to 'butt into' the field, Burrage's name was on record in the Poor Debtor's Court. He conceived the idea of securing for Rogers control of the Brookline Gas Co., which had a charter that permitted it to enter Boston, and with this weapon he and Rogers gave battle successfully to Addicks and finally drove him from the field. Following that coup, Burrage was taken up by the Standard Oil Co., and afterward Thomas Lawson was also called into service. Burrage and Lawson, in connection with Standard Oil, framed the Amalgamated deal and also the Arcadian, the first copper exploitation in the Lake country with which Standard Oil men became identified. Burrage and Lawson

NATIVE WORKINGS, CHUQUICAMATA.

also put out Trimountain, which afterward entered the Copper Range fold. On the transfer of Trimountain to Copper Range hangs a tale which in August 1905 resulted in the 'Copper Range war', as it is known to this day in Boston. William A. Paine stopped the transfer of a lot of Copper Range stock which had been sold, claiming that Burrage and Lawson had broken the pool into which they had entered when Copper Range took over Trimountain. A deadlock resulted which gave State Street the appearance of Wall Street in May 1901, when the Harriman and Hill fight boosted Northern Pacific to \$1000 per share. William A. Paine took a stand against Burrage, Lawson, and the entire Boston Stock Exchange, but it was ruled that the Copper Range stock would have to be transferred. Paine then took his case to the courts, suing Burrage and Lawson for \$6,000,000; a suit that may still be pending, never having come to trial. Burrage, from a lawyer who at one time had to take the pauper's oath, has become one of the richest men in Boston, with costly residences here and in California and a palatial steam yacht.

It is reported here that there is at least just a suspicion of a split in the ranks of the Cole-Ryan Syndicate. John D. Ryan has caused it to be made known that he is not interested with his old-time partner in the acquisitions of territory being made in the northern and northwestern part of Butte, beyond the North Butte and Butte & Superior properties. It is said that there has been increasing separation of these two men for some time. A great many people confuse Amalgamated and Cole-Ryan, one a corporation and the other a syndicate. In Bisbee neither Calumet & Arizona nor Superior & Pittsburg were Amalgamated-Cole-Ryan properties. It is also true that in Bisbee the so-called Cole-Ryan syndicate has never had any influence in these two companies other than that exercised by Thomas F. Cole personally. The Amalgamated policy of forming a copper

merger of United States Steel Corporation calibre has never appealed to the principals of the Bisbee companies, who do not believe that the price of copper can be controlled that way. James Hoatson first interested his brother-in-law, Thomas F. Cole, in Calumet & Arizona, and the probabilities are that the Cole and Hoatson interests in the future will act together more than the Cole and Ryan interests. Mr. Ryan is considered to be a party to the Keweenaw consolidation in the Lake country, but only in a formal way. The Cole-Ryan syndicate may remain intact as to past enterprises, but it is quite well known here that there is little or no disposition on the part of either Cole or Ryan to increase their joint interests. The exploitation of the northern and northwestern part of the Butte district is interesting Thomas F. Cole, A. B. Wolvin, and a number of other Duluth men, the Duluth interests probably being dominant in that movement.

### JOHANNESBURG, TRANSVAAL

SEPTEMBER RETURNS.—DEEPEST MINE IN THE WORLD.—  
OTHER DEEP MINES.

September being a 30-day month, the output of gold for the whole of the Transvaal was 16,844 oz. less than during August, the total production being 747,893 oz., value £3,176,846; of this, 716,495 oz., value £3,043,475, came from the Rand. The Randfontein Central crushed and treated 201,652 tons, with a recovery valued at £259,944; the Crown Mines, 156,300 tons, with a recovery of £245,366; and the East Rand Proprietary Mines, 140,800 tons, with a recovery valued at £240,931. It seems strange that the East Rand Proprietary Mines should be able to supply the mills with a better grade of ore than the Crown Mines, which for many years has been counted among the richest properties of the Rand. The Ferreira Deep milled 53,140 tons, yielding £106,265, and the Robinson mine 51,400 tons, yielding £101,457, so that there shortly ought to be about half a dozen mines on the Rand producing gold in excess of £100,000 per month.

The tendency has been of late to amalgamate those outcrop properties now on the point of exhaustion with the deeper neighbor, more especially where both the mines are under the same control. The Village Main and the Village Deep seem likely to follow this example soon. It cannot be said that the reduction in the railway freight on coal to the gold mines seems to have had the anticipated improvement upon September profits, as the group profits, which cover nearly the whole of the Rand profits, were less in September than July. It was calculated that the rates would make a saving to the gold mines of over £200,000 per month, but so far the saving does not materialize in either lower costs or higher profits. Perhaps the Victoria Falls Power Co. reaps most of the benefit from the lower coal rates.

It is believed that the Jupiter mine, near Germiston, long the possessor of the deepest vertical shaft on the Rand, is now the deepest gold mine in the world. At its lowest point the face of the incline is at a total depth from the surface of 5040 ft. The vertical shaft, known as the Catlin shaft, has a depth of 4243 ft. and a further vertical depth of 800 ft. is obtained by following along the reef on the incline. The Jupiter mine is situated about half way between Germiston and Johannesburg, to the immediate dip of the Geldenhuis Deep mine, which of late has fallen somewhat in its grade, although the Geldenhuis Deep was the first deep-level mine on the Rand to produce gold. The Jupiter company has a nominal capital of over a million sterling and was registered in 1896, but so far has only paid one dividend of 5% to its shareholders, the monthly profits varying from £2000 to £4000. The mine is well developed and equipped with a modern ore-reduction plant and has passed through various vicissitudes, especially as to the grade of its developed ore. It is recognized as being in a low-grade area, a common fault of all the three deepest mines in that section of the Rand.

The Jupiter, now the world's deepest gold mine, adjoins the Simmer Deep on the west, where the lowest level has

now reached a depth of 4580 ft. from the surface. The capital of the Simmer Deep is £1,650,000. It has never paid a dividend, and working at such a depth on ore estimated to yield only 18s. per ton does not, with present Rand working costs, seem likely to do so in the immediate future. Like the Jupiter, it is a splendidly equipped mine, and no efforts or expense have been spared by the controlling house, the Consolidated Gold Fields of South Africa, to enable the mine to give a good account of itself. It may almost be said to have been worked in unison with the Jupiter mine and a good deal of what has been said about the Jupiter also applies to the Simmer Deep. Another very deep mine on the Rand is the Cinderella Deep, close to the town of Boksburg and immediately to the dip of the eastern extremity of the property of the East Rand Proprietary Mines. The shaft here, however, has only a vertical depth of 4000 ft., but the total depth from the surface at the lowest point of the incline is 4770 ft. All these three deep mines have had numerous mining and ventilation difficulties to contend with, particularly the Cinderella Deep, which at present is only in possession of a single shaft. The connection made to the rise with the East Rand Proprietary Mines is of such little value that in some of the workings the temperature is as high as 92°F. Air-blasts, too, have played sad havoc with all these deep mines, particularly with the Cinderella Deep, where, due to this cause, the mine was worked for two months recently without making any profit. Judging, however, from the difficulties surrounding the deep gold mines in South America and Australia, the Rand is destined to become the home of deep mining. No matter how troublesome deep mining may appear on the Rand, it is quite easy work compared with other countries, and only the value of the local blanket reefs will in the future place a limit on deep mining here, for undoubtedly the reefs will be followed down so long as it is proved profitable to do so. But it must be pointed out that so far the deepest mines have not been at all satisfactory as producers of profit.

### LONDON

#### A WORLD-WIDE EXPLORATION COMPANY.—NEW MANAGEMENT FOR EAST POOL.—THE MAYFIELD SYNDICATE.

On the exhaustion of some of the Kalgoorlie mines a few years ago, F. A. Govett, the chairman of the controlling companies, asked H. C. Hoover to scour the world for new properties. Thus began the foundation of a promoting business which is now beginning to loom large on the London horizon. The rearranged controlling company is at present called the 'Lake View & Oroya Exploration,' but it will be necessary to find some more suitable name before long. Among its holdings are blocks of shares in the Leonesa mine in Nicaragua; the Kyshtim and the Orsk Goldfields in Siberia; the Fitzroy mine in Queensland; the Block 10, South Blocks, Zinc Corporation, and Amalgamated Zinc companies at Broken Hill; the Black Range, Mountain Queen, Transvaal, and Queen of the Hills mines in Western Australia; and the Granville and Boyle's Concession in the Yukon. Some of these are promising, and some are yielding handsome profits. The geographical range is great and bespeaks the wide experience of the controllers. They have as much knowledge of mining, in its world-wide aspects, as any group in London. Besides Messrs. Govett and Hoover, there is A. Chester Beatty, well known in America, though he is not yet a director. Among the directors of the company are Tynedale White, the chairman of Tanganyika Concessions, and W. F. Turner, the chairman of the Anglo-Continental, both gentlemen who must have learned a good deal from experience. Besides Mr. Hoover himself, the board includes another mining engineer of high standing, J. H. Corder-James. Thus the talent is ample for big work, and much will be expected from the company.

Mr. Hoover became interested also in oil some time since, and with Mr. Beatty has been the dominating figure in the Continental Oil Co., owning lands in the Midway and Coalina fields of California and 5500 acres in the oilfields of

Eastern Mexico. The company has made no attempt to force production and has now sold out to the General Petroleum Co., controlled by Eugene De Sabla and his friends. It is understood that Messrs. Hoover and Beatty become stockholders in the enlarged General Petroleum.

I have often recently mentioned that Cornwall is once more coming into its own. The news of greatest importance this week is that Bewick, Moreing & Co. has taken the management of East Pool, one of the last of the east-book mines, situated close to Dolcoath, South Crofty, and Carn Brea & Tincroft. For eighty years this mine has been yielding profits from tin, tungsten, and arsenic, and the directors and managers have a fair claim to the honor of being the leading initiators of up-to-date methods of ore treatment. On the other hand, the development work has of recent years been allowed to lag behind. Frankly, the depth and the water conditions have been such that more money was required for capital expenditure than could be raised by assessing east-book shareholders. For some time the directors have been looking for an opportunity to break away from tradition and introduce a large amount of new money. The details of the new deal with Bewick, Moreing & Co. are not yet fixed, but in all probability I shall be able to give fuller information next week.

The details of the Rayfield (Cornwall) Tin Syndicate have been published this week by Oliver Wethered, the chairman, and as it promises to be one of the most important companies connected with mining ventures in Cornwall, a résumé of its scope and objects should be given. The capital of the Syndicate, £75,000, has all been subscribed in cash, by shareholders in the Rayfield (Nigeria) company, and there are no promotion shares or money to be paid. The cost of formation and brokers' commissions was only £1000, so the Syndicate had £74,000 in cash to start with. Interests have already been acquired in the Gwithian Sands, the Basset & Grylls mine, Geevor Tin Mines, the Zennor and Ludgvan leases, the North Dolcoath, and the Killifreth mine. Of all these the Gwithian Sands will probably be the most attractive at first. As is well known, the Red river carries tailing from the Camborne mines to the sea at Gwithian, in St. Ives bay, and though this tailing is re-treated several times on its way down, it still contains an appreciable amount of cassiterite. This is gradually concentrated by the action of the sea, and has provided David Stevens with a substantial living for forty years. A year ago a Cornish group undertook to work the sand on a larger scale by modern methods, and instructed C. G. Lush to examine and report. Mr. Wethered came in with a bid for a half interest, and at the instruction of Percy Tarbutt & Co., R. C. Nicolaus made another inspection.

Mr. Nicolaus took 841 samples from 447 pipe bore-holes, 155 pits, and 37 drill-holes, and reported the presence of 1,208,725 tons of sand averaging 6.45 lb. metallic tin per ton. The thickness of the deposit is reported as 36 in. Some is above and below the high-water mark, and Mr. Nicolaus recommends that that below, amounting to 594,905 tons, should for the present be eliminated from the estimate. He has since issued a supplementary report adding 82,392 tons to the reserve, making it 696,212 tons above high-water mark. The cost of treatment is estimated not to exceed 4s. per ton against an average content worth 18s. 3d. per ton with tin at £229. The recovery was figured at from 60 to 70%. With regard to the other properties mentioned, the Basset & Grylls mine, in the Wendron district, has been entirely purchased by the Syndicate. It is proposed, in the first place, to re-grind and re-treat the dump ores and the plant for this purpose should be ready in a month or two. The mine will be developed later. E. S. King & Co. have this matter in hand. The Zennor, Ludgvan, and North Dolcoath properties were acquired jointly with the Rayfield (Nigeria) company. As regards the Killifreth, that mine yielded profits in former years and was closed when the price of black tin fell to £40. The Syndicate had undertaken jointly with other parties to provide £40,000 for its reopening and rehabili-

tation. Altogether, therefore, the Syndicate has some important and promising business in hand, which will be watched with unusual interest.

### BUTTE, MONTANA

PROPOSED HYDRO-ELECTRIC CONSOLIDATED.—NEW ZINC COMPANY.—LA FRANCE TROUBLES.

The proposed consolidation of electric power companies in Montana is a matter of decided importance to the mining industry. The Butte Electric & Power Co. at the next stockholders' meeting will vote on a proposal to consolidate with the Missouri River Electric & Power Co., the Madison River Power Co., the Billings & Eastern Montana Power Co., and the Montana Power Co. If the terms are accepted by the stockholders, a new company will be formed to be known as the Montana Power Co., capitalized at \$100,000,000. Of this capital, \$75,000,000 will be apportioned to common shares, and \$25,000,000 to 7% cumulative preferred shares. The company is to have the right to redeem the preferred stock after three years at 120. Ten preferred shares of Butte Electric & Power will be exchanged for eight preferred and two common shares of the new stock. One common share of the old stock will be exchanged for four common shares of the New Montana Power Co. The other companies absorbed will receive \$3,900,000 for their properties. The Montana Power Co. will secure the money for the purchase by issuing preferred stock at par. This issue may be purchased by Butte Electric stockholders to the extent of 50% of their present holdings in preferred or common stock of the old company. Payments for the new preferred stock will be called for January 12, 1913. When the present plans of financing are completed there will be left in the treasury of the new company about 80% of the preferred stock and 60% of the common stock, or 68% of the total capitalization. The new organization will be controlled by Butte Electric interests. O. W. Wetmore, of Boston, is to be president, and Max Hebgren, of Butte, is to be vice-president and general manager. The Great Falls Power Co. is not to enter the new merger, but some of the largest stockholders are interested in both companies, so that the interests will probably not conflict. At first thought it might seem that such a consolidation would be detrimental to the consumer, but with the present limited development of the country the reverse will be the case. The available power is far above the present needs of the state.

The Rainbow Lode Development Co. has been organized by Duluth capitalists to prospect a group of claims east of the property of the Butte & Superior C. M. Co. The claims controlled by the new company are the Third Sphinx, Michigander, Morel, Valley Queen, Forest Rose, Wanda, Cornbrea, and a fractional interest in the Sarah. The company is also interested in the Butte and London Copper Development Co., to the extent at least that an arrangement has been entered into whereby the latter company will cross-cut the Rainbow property at a depth of 1600 ft. The present depth of the Butte and London shaft is 1100 ft. This is to be sunk an additional 500 ft. Edward C. Congdon is president of the new company, and among those associated with him, are Chester A. Congdon, and Thomas F. Cole, all of Duluth. The Rainbow Lode Development Co. is capitalized at \$8,000,000 divided into 800,000 shares of a par value of \$10.

The United States Government has brought suit against Albert W. McCune to recover \$2,512,955, the alleged value of cordwood cut by McCune and associates from Government land. The wood was cut during the years 1883 to 1895, and amounted to 717,987 cords, according to the complaint. The wood was delivered under contract to the old Anaconda smelter. The Government's excuse for the long delay in bringing the action is that the defendant has been out of the country much of the time, and that his fortune has been kept in such a shape that the Government could not recover on it.

While drilling last fall for a water supply for the new Clark concentrator, a flow of artesian water was developed.

Speculation was rife concerning the possibilities of such a supply and government aid was secured to advise on the matter. O. E. Minzer of the United States Geological Survey was detailed to investigate conditions, and has submitted a preliminary statement to the Butte Chamber of Commerce. In brief, Mr. Minzer says that the flat south of Butte will not furnish artesian wells, but that it is a large debris-filled basin covering about 100 square miles and surrounded on all sides with mountains, the streams from which are largely absorbed by the basin. Wells sunk in the basin will tap this supply, which can be made available by pumping. The supply is regarded as ample for all probable uses.

Another of F. Augustus Heinze's flotations is in trouble. On November 7, Judge McClernan of the local district court granted a default judgment against the La France Copper Co., in favor of the Lincoln Trust Company of New York, for \$2,735,600, and directed that the property be sold at sheriff's sale. La France Copper Co. was organized in 1905 to take over the old Lexington mine and mill owned by French capital. A surface plant was erected, and some underground work was done. The ores were mixed sulphides, and concentration was attempted in a 200-ton experimental mill using an electrostatic separating process. The company has failed since 1908 to meet the interest on the \$2,000,000 worth of outstanding bonds. It is the intention of the bondholders to reorganize the property, and endeavor to find a satisfactory method for treating the ores. There is said to be a large tonnage in the mine, running about 1% copper, 3% lead, 18% zinc, with \$4 in precious metal content.

The East Butte Copper Mining Company produced over 1,300,000 lb. of copper in October, with average net earnings in recent months of better than \$100,000 monthly. It is the desire of the company to enlarge its furnaces to a capacity of 2,000,000 lb. of copper per month, but no attempt will be made to do this as long as the present high price of copper continues, because the enlargement would necessitate a delay of possibly two months. Shaft-sinking has been resumed at the Pittsmont, and the shaft will be deepened to 1800 ft., and possibly 2000 ft. The shaft sinking will be carried on without interruption of the present production from the upper levels of the mine.

### TORONTO, CANADA

DISCOVERIES AT CART LAKE.—THE SENECA-SUPERIOR.

Recent discoveries on the Seneca-Superior lease, Cart Lake district, Cobalt, have revived interest in a portion of the district, well within the productive area limits, which has been regarded more or less unfavorably, although it has been admittedly but partly explored. All of Cart Lake is included within the property lines of the Nipissing company, except at the south end, where the Savage and Provincial companies have productive properties. The lake bed is under control of the Peterson Lake company, under separate location, and the Seneca-Superior is leasing from that company. The work of exploration was renewed about six months ago, a shaft being sunk to 200 ft. on the east edge of the lake and a cross-cut drift advanced to the east across the lake bed. Several barren leached veins were cut in the first 200 ft., and at about 400 ft. a small ore stringer was found, succeeded by the strong vein, 4 to 6 in. wide and containing solid ore assaying 2000 to 4600 oz. in silver. The vein has been opened laterally about 40 ft. and is still strong and high grade. This discovery will give strength to the large area of Nipissing east of the lake on which a shaft is now down 300 ft. in the conglomerate, and to the Nipissing area east of the lake on which the No. 86 vein is partly developed. The Seneca-Superior ore is cut in the conglomerate probably 50 ft. above the Keewatin contact. It is not yet possible to correlate this vein with the other proved veins to the east and south. The Seneca-Superior operation is in charge of R. H. Lyman, formerly of Pachuca, Mexico. The development was undertaken under the advice and direction of W. E. Segsworth, of Toronto, as engineer, and Kirby Thomas, of New York, as consulting engineer.

## General Mining News

### ALASKA

#### JUNEAU

It is reported that 500 men are employed at the Alaska Gold Mines property. At the Perseverance claim no mining is being done. The mill is running full time and is being used to test the ore for the best treatment. At the mine one of the principal developments is the widening of the Alexander cross-cut. Three sawmills are at work cutting lumber for the different plants; the foundations for the power-plant are excavated, and all the wiring of transmission lines is completed, and electrical machinery is arriving. At the Sheep Creek tunnel, which will be driven to cut the lode at greater depth, concrete foundations are finished, and a compressor is being erected.

#### VALDEZ

Rich gold ore has been opened at the Minnie claim, situated about six miles from the head of Shoup bay, and near the property of the Cameron-Johnson company, Gold Hill, Mayfield, Rambler, and Bence-McDonald. An adit has been driven some distance, and work will be continued through the winter.

### ARIZONA

#### MOHAVE COUNTY

High-grade lead and zinc concentrates are being shipped from the Banner mill, from ore from the de la Fontaine mine. Shipments of bullion from the Gold Road mill average about \$25,000 per week, and it is expected to increase them to \$200,000 per month when the new mill is in operation. It is reported that the Clark interests have bonded several mines at Brownsville, in the Cottonwood district. Kirk & Lavell have taken an option on the C. O. D. and will begin work soon. A bar worth \$6000 was recently produced from a 10 days run of the Frisco mill.

#### SANTA CRUZ COUNTY

The Copper Queen company has taken over the Bradford mine, from which one car of carbonate ore per week is now being shipped. At the R. R. R. mine one 50-ton car of ore per day is being shipped to the El Paso smelter. A large tonnage of low-grade ore is accumulating on the dump. Six machine drills and a force of 70 men are at work. W. S. Sultan is in charge. The Chief group of claims has been bonded by the El Tigre company and a 500-ft. exploratory adit started. The ore contains copper, lead, and zinc. The Hosey mine has been bonded by Posey and Frazier. Shipments of copper-silver ore are now being made at the rate of 3 cars per month.

#### YAVAPAI COUNTY

Work will be resumed at the Pittsburg-Jerome mine, situated southwest of Jerome, and a burro train of 19 animals recently brought supplies to the property. The principal work at present will be in the main adit, which is in several hundred feet. The Haynes Copper Co. will also resume development, and power will be obtained from the Arizona Power Co. The Haynes mine is northwest of the United Verde. It has been decided to increase the Juanita mill by 10 stamps. After lying idle for many years, the Crown King mill is to be started. Six concentrating tables have been installed, and the large dump of tailing left when the mine shut down will be reground and concentrated. Besides the gold in the tailing, zinc will also be recovered. Sixteen men are employed in development at the Copper Queen, near Mayer. A few men have started work at the Mark Twain, in the Slate Creek district. The ore has a high content in lead and silver.

#### YUMA COUNTY

A 90-ton Lane mill, 4 Johnston vanners, a 40-hp. engine, and a 3-ton motor truck have been ordered for the D. & W. mine. Large orebodies averaging \$12 to \$16 per ton in gold have been developed in the 700-ft. shaft and 40 men are at work on the property. J. W. Flink is superintendent. Extensive claims are made as to the value of the

property of the Arizona-Empire Copper Mines Co., and it is said that large shipments of ore will soon be made. It is proposed to eventually build a railroad to the property and to erect a smelter. C. W. Mitchell is manager. Development work at the Mack property is so encouraging that a new contract has been let for development work. Good ore is being sacked on the Empire Flats property, which was recently bonded by W. W. Andrews to San Diego investors.

### CALIFORNIA

#### BUTTE COUNTY

(Special Correspondence.)—The Hupp Gold Mining Co. has acquired the Hupp placer claims in the Magalia district and is driving to intersect the Indian Springs channel. G. K. Orr is superintendent. The mine is situated near De Sabla. The P. B. Steifer Mining Co. has unwatered its Magalia property for the first time in four years. New machinery has been installed in the power-house, and it is planned to continue development throughout the winter. A dam has been constructed across the west branch of the Feather river for the generation of water-power. Los Angeles and Eastern people are interested. The Superior Channel Mining Co. has been formed to operate on 600 acres near the Steifer property. The Cohn company continues to mine a good grade of gravel and is the largest operator in the Magalia district. San Francisco people are said to be interested. L. Cohn is manager. The Robbers' Roost company is arranging to begin work. A three-mile pipe-line is being built to the claims from the reservoir of the Pacific Gas & Electric Co. San Francisco people compose the company. R. T. Hooper is president and W. F. Anderson manager. Ten companies are operating in the Magalia district at present.

Chico, November 11.

The Gold Bank, near Forbestown, has been taken over by San Francisco interests, and a 40-stamp mill is being built. The Brown Bear M. Co. has been formed with a capital of \$250,000 in shares of \$1 each. The incorporators are: C. B. Whitmoyer, Marvin Gary, J. W. Charge, James N. Crabb, and L. A. Snow.

#### FRESNO COUNTY

W. P. Hammon has completed the purchase of 160 acres of oil land in the Coalinga district from the Empire, Republic, and De Luxe oil companies, on which payments have been made for about a year. There are 12 producing wells on the property.

#### INYO COUNTY

L. D. Godshall has taken over the old Tecapa property, near Resting Springs, and will soon have a large force of men at work shipping ore to the smelters near Salt Lake. The ore contains an iron excess and the gold, silver, and lead content is worth \$8 per ton. It is reported that a 16-mile railroad will be built from the Tonopah & Tidewater, at Silverlake, into Death Valley to facilitate shipping of salt from that region.

#### MARIPOSA COUNTY

The Oro Rico, which has been shut down for some time, has resumed operation in its 20-stamp mill. The Clearing House, which had been shut down from lack of water, has resumed work. Work on the power-line to the Melonia and the 40-stamp mill of the Merced M. Co. is nearing completion. A company has been formed to develop the Virginia, four miles east of Coulterville.

#### MODOC COUNTY

(Special Correspondence.)—The Ft. Bidwell Mines Co. has been organized under the laws of California to acquire the holdings of the Ft. Bidwell Con. Mines Co. The properties were purchased at sheriff's sale for \$12,167 by representatives of old stockholders. An assessment of 1c. per share was recently levied, and old stockholders have until December 2 to make payment. According to the statement of officials, such stockholders will be given a just share in the new company. The new concern is capitalized at \$1,000,000. It is said steps may be taken to continue de-

velopment work at the Mountain View claim. Los Angeles people are interested, but bulk of stock is held by Detroit residents. J. M. Stone is president.

Ft. Bidwell, November 14.

#### NEVADA COUNTY

(Special Correspondence.)—With the payment of its third quarterly dividend for this year, September 28, the North Star mine has distributed a total of \$3,661,986 in profits under present ownership. It is expected the fourth quarterly dividend, and a possible Christmas payment, will be paid before the close of 1912. Much of the ore now crushed comes from a depth exceeding 4000 ft. on the incline. The two 40-stamp North Star and Central mills are operating at full capacity. The North Star company is also arranging for the erection of a cyanide plant at the Champion mines, Nevada City. It is understood that construction will commence within a few weeks. Good ore is reported at several points in the Champion workings. Arrangements are under way for the completion of the power-line to the Normandie group of claims, about four miles below Grass Valley. Recent storms caused a temporary suspension of work at the property. San Francisco people are interested. Horace Jones is manager. Several sacks of rich quartz have recently been sent to Nevada City from the Morning Star mine, on Badger hill. John Curnow, of Cherokee, is owner. Salmon Bros. report good ore showing in their claim, in the same district. Development at the Oustomah mine is encouraging. Klinker Bros., of Los Angeles, are operating the property under option. L. W. Klinker is manager.

Grass Valley, November 18.

#### COLORADO

##### CLEAR CREEK COUNTY.

(Special Correspondence.)—Hurley & Co., leasing in the Harris mine in East Argentine district, have started shipping high-grade ore which mills as high as 2200 oz. silver per ton. Work through the shaft has been resumed on the Manhattan Union property. The Silver Glance mine on Democrat mountain, a heavy producer of high-grade ore in the early days, is to be reopened through the La Plata adit, a right of way having been secured. Ore is found with a silver content of 350 to 700 oz. silver per ton. A. McClelland, of Pueblo, is owner. Heavy shipments are going out from the Gold Fissure mine at Empire. The ore is concentrating grade and is being consigned to the custom mills for treatment. Willis Bristol is manager. The Toledo property in East Argentine is receiving attention. The lower adit is being driven and a small streak of ore is showing in a vein recently cut. Work is to be resumed on the Domino property on Green Lake mountain. H. Cochran is owner. F. Winters, Sr., is developing the Black Prince property and an 8-in. streak of quartz is showing in the bottom of the 30-ft. shaft that carries \$42 per ton in gold and silver. Criley Bros., owners of the High Five group of claims on Alpine mountain, have resumed development in the lower adit.

Georgetown, November 18.

##### LAKE COUNTY (LEADVILLE)

The Cramer mill, which was moved from its site at the head of East Fifth street to the old Elgin smelter, is now nearly in working order. Power is now supplied by steam. Ore from the old McHarg dump will be the first ore to be treated and will be crushed and passed through a set of jigs. Lessees at the Ella Beeler adit, Iowa gulch, have cut a good orebody containing lead, with some gold and silver. What is known as the 600-ft. level of the Emmett shaft, Carbonate hill, is being cleaned out and repaired by lessees of the Denver City and Blaine shafts. Lessees at Highland Chief and Eliza, Breece hill, are working on a fair vein of carbonate of zinc. At the 600-ft. level of the Denver City and Gambetta, carbonate ore averaging 33% zinc is being opened. At the North Moyer, Nevada, Adelaide, Annie, and Modoc, lessees are busy on development or shipping ore.

#### TELLER COUNTY (CRIPPLE CREEK)

The output at the Mary McKinney during October was 30 cars of \$30 ore by the company and 8 cars by lessees. E. T. Smith has found rich ore in the Howard shaft. The water has receded from the 900-ft. level, and driving is in progress on that level, the company having 45 men at work. Production at the Jerry Johnson during October was 15 cars of 1-oz. ore. There are four sets of lessees, but Frank Caley produced nearly one-half of the total ore. The Kavanaugh mill, constructed to treat the ore on the Jo Dandy dump, is handling 60 to 75 tons per day and is reported to have repaid the cost of construction in five months, though paying 12½% royalty to the Jo Dandy company. The quarterly report of the Doctor-Jack Pot shows that 993 tons of ore of an average content of \$22.09 per ton was shipped, with a net profit of \$2139. Cash on hand amounts to \$23,000. Decision in the suit of the company against the Work M. Co. is expected at an early date. The Granite G. M. Co. has paid a dividend of 1c. per share, making a

ROOSEVELT DRAINAGE ADIT, CRIPPLE CREEK.

total of \$286,500 to date. The total flow from the Roosevelt drainage adit was 9060 gal. per minute on November 10. The directors of the Gold Dollar M. Co. have declared a dividend of ½c. per share, amounting to \$12,000. Production during October was 1212 tons. The electric pumps in the Golden Cycle have been started. Work has been started on the 450-ft. Masterpiece adit. A 100-hp. compressor will soon be installed at the Jo Dandy main shaft.

##### THE SAN JUAN

Recent reports from the Camp Bird mine indicate a probable additional profit of \$300,000 to be derived from working. About 50 tons of ore per day is now being mined. The ore mined during the past year averaged \$26 in gold content and an extraction of 94.7% was made. Machinery is being taken to the Humboldt and Mountain Top, near Ouray. The compressor has been installed at the Sweepstakes. The new zinc concentrator at Ouray, owned by Foerster & Lowe, started work the middle of this month. It will treat the concentrate from the Micky Breen, Barstow, Atlas, and Revenue. The annual report of the Tomboy for the year ended June 30, 1912, shows a profit of \$430,000. G. H. Barnhardt has taken a 5 years option on the Tierra del Fuego group, on the north slope of Mt. Sneffels, on behalf of the Mountain Top M. Co. There is a 200-ft. adit on the property, and it is claimed that a 7-ft. vein is exposed, averaging \$23 per ton.

J. N. Pascoe, under the auspices of the Silverton Commercial Club, is planning to build a 200-ton custom milling plant at Silverton next spring. The local railroad has offered low freight rates on ore shipments and it is hoped to make the venture a success.

#### IDAHO

##### CLEARWATER COUNTY

W. J. Harris has won his suit over 40 acres of placer ground on Quartz creek, in the Pierce district, and is planning to construct a \$50,000 dredge. The other dredging properties in the district are making good operating profits.

##### IDAHO COUNTY

The Moscow group of mines has been sold by M. E.

Moore to E. T. Smith, representing Seattle and Los Angeles people, for \$150,000 in cash. The property is on Logan creek, 90 miles by wagon-road from the railway at New Meadows, but a new railroad line up Long valley will decrease the distance to 20 miles. The underground development shows ore averaging \$3 per ton over 150 ft. in width, the orebody being 4000 ft. long. A cyanide plant will be constructed.

#### SHOSHONE COUNTY

The Marsh mine at Burke has been purchased by E. J. Carter and Volney D. Williamson, who have taken the control of the 1,290,000 issued shares. The Black Horse, in Paragon gulch, near Murray, is working 20 men, and its 50-ton mill is crowded to full capacity. The suit of E. J. Carter against the officers of the Stewart Mining Co. has been dismissed, having been compromised. All moneys loaned by the Stewart company to the Ohio Copper Co. and other corporations have been repaid; all moneys due from different smelters to the Stewart company, as alleged in the Carter complaint, have been accounted for; all the stock of the Coeur d'Alene Development Co., and all the demands of the plaintiff relative to an accounting of the Stewart's business for the last several months prior to the beginning of the action have been complied with. It is further stipulated that the defendants pay all costs of the action and that a satisfactory accounting of the business of the company be rendered at stated intervals. M. W. Bacon, general manager, states that the company now has between \$350,000 and \$400,000 in the treasury and has been earning at the rate of \$60,000 per month since the litigation was begun. It is stated that the company should be able to pay a dividend soon.

#### MONTANA

##### BROADWATER COUNTY

On good authority, it is stated that work is to be resumed on the Three Forks & Radersburg railroad, and that it will be completed into the Radersburg district before spring. This will give an important impetus to mining in that section, as several mines are ready to ship low-grade ore that would not pay with the old wagon haul to Toston. The Keating Gold Mining Co. has extended its inclined shaft on the Blacker claim to the 800-ft. level, and a new pump is being installed. A large tonnage of ore is blocked out ready for stoping. With the advent of the railway the mine will increase its shipment from 100 tons per day to 250 tons. The Ohio-Keating Mining Co. and the Black Friday Mining Co. are also prepared to ship. Although the veins of Radersburg are narrow, the orebodies persist in depth, and the ore is of a character favorable to cheap smelting rates. The average ore shipped will carry about \$20 gold per ton.

##### DEER LODGE COUNTY

The completion of the Georgetown extension of the Butte, Anaconda & Pacific railway has stimulated prospecting in all tributary territory. The latest find is in Stuckey's gulch, seven miles west of Anaconda. Samples assaying as high as \$270 per ton in gold have been taken. Copper in commercial quantities is also reported from this gulch.

##### JEFFERSON COUNTY

The Ex-Vein Mining Co. has been organized by Butte interests to develop the Bullock property on Basin creek, near the old Bullion mine. Some ore was mined from the property in early days. Operations are to begin at once, and the property will be developed by means of adits.

##### LEWIS AND CLARK COUNTY

The St. Louis Mining Co. at Marysville is constructing a 100-ton milling and cyanide plant. Tube-mills are to be used for regrinding. The mill is designed to handle the big bodies of low-grade ore still in the Drumlummon mine.

#### NEVADA

##### ESMERALDA COUNTY

The suit against the Merger Mines has been settled in favor of the company. Five Johnston vanners have been added at the Bonnie Clare mill, which is treating the ore

from the Polverde; only 10 of the 20 stamps are in use. The Vernal has made a shipment of \$40 ore. Rich ore is being shipped by the Florence. The shaft of the Goldfield Oro will be sunk to the 1000-ft. level.

##### LINCOLN COUNTY

The following Pioche mines have filed statements with the county assessor of shipments made during the quarter ended September 30:

	Tons.	Value.
Prince Con. M. & S. Co.....	8846	\$152,577
Day-Bristol Con. M. Co.....	2027	44,889
J. A. Nesbitt, tailing shipped Conda canyon .....	2852	39,972
Mendha-Nevada M. Co.....	993	9,803
P. Sheahan, dump ore.....	65	2,553
Home Run Copper Co.....	57	2,431

The main shaft of the Nevada-Des Moines M. Co. is being sunk from the 350 to the 500-ft. level, where diamond-drill holes cut silver-lead ore assaying 608 oz. silver and 31% lead. B. J. Cavanaugh is president of the company.

##### NYE COUNTY

The West End shipped \$53,600 worth of bullion and 50 tons of concentrate during October. The October yield of the Tonopah Mining was \$135,765, while the McNamara output exceeded \$26,000. A new hoisting plant has been constructed at the Halifax. The Tonopah Belmont net profit for the month was \$166,000, and the total tonnage milled in the district 129,953.

##### WASHOE COUNTY

(Special Correspondence.)—The recently incorporated Reno Smelting & Refining Co. is going ahead with its project to erect a \$500,000 custom plant at Reno. The site has been secured and it is planned to commence work within a few weeks. The Loder system of smelting will be used. John S. Loder is consulting engineer. A movement has been launched to organize a prospectors' association in Nevada, with headquarters at Reno, to assist in exploiting prospecting and legitimate mining, and protect prospectors in the development and disposal of their claims. A rich silver-lead discovery is reported from the Curry lease on the Arkell mine, northeast of Reno. Samples of the ore are stated to assay \$100 per ton. Edwin Arkell is owner. It is reported that a company of Kansas City and Los Angeles people plan the prospecting of Peavine mountain for copper ore. Options have been taken on several tracts, and it is stated that churn-drills will be used. The find recently made at the Nevada Deep mines, Como district, is reported to be showing well with development. The shoot was intersected on the 50-ft. level of the Star of the West claim and parallels the Como vein. Samples of quartz are said to assay over \$300 per ton, with gold predominating. H. L. Taylor is president and manager.

Reno, November 17.

#### NEW MEXICO

##### SOCORRO COUNTY

(Special Correspondence.)—At the Socorro Mines custom ore is now being received from three different properties and two more are getting ready to ship to the plant. Good ore is coming from the lowest levels of the mine. The shaft is going down steadily and will soon be at the 900-ft. level. The average daily tonnage handled in the mill is 165 tons. The output of the Ernestine Mining Co. for the last 11 days of October was 10,530 oz. of gold and silver bullion and 9600 lb. of high-grade concentrate; the total for the month was 33,080 oz. bullion and 25,100 lb. concentrate. The regular monthly dividend of 1% was declared November 1.

Mogollon, November 15.

#### UTAH

##### BEAVER COUNTY

Construction work is now in progress at the Moscow property and a new hoisting plant, additional boiler plant, and better roads to the property are being provided. One unit of the Cactus mill of the South Utah Mines & Smelters

Co. is being readjusted to handle the low-grade lead-zinc ore from the Horn Silver. It is stated that nearly 300,000 tons of ore of this grade has been developed. A fair tonnage of shipping ore is being sent to the smelters at present.

#### JUAB COUNTY

The Lowland Tunnel, Water & Transportation Co. has been incorporated with a capital of 1,000,000 shares of 1c. each, for the purpose of driving a 10,000-ft. haulage adit to furnish an outlet for 12 properties in the district. E. P. Jennings is president, Louis Fugal vice-president and general manager, and Clark L. Whitney secretary and treasurer. These, with George F. Wasson and A. S. Sundberg, compose the directorate. The tunnel, it is declared, is now in 125 ft. and will give a depth of 4459 ft. in one place. In the Iron Blossom the vein is increasing in width above the 500-ft. level. South of the No. 3 shaft on this level there is a large body of ore of shipping grade. The vein has recently been opened on the 700-ft. level at the No. 1 shaft. Good ore has been found on the 1300-ft. level of the Eagle & Blue Bell and has also been cut on the level 115 ft. below. Ore of shipping grade has also been cut on the 1100-ft. level of the May Day and the property is likely to become a large zinc producer. The Bullion Beek will soon be shipping zinc ore, as L. C. Doty, the superintendent, is driving on the 1300-ft. level to develop a good body of zinc ore. Good ore has recently been developed on the 500-ft. level of the Gold Chain, about 1000 ft. from the shaft. W. D. Loose is assistant manager. In the Grand Central mine, under the same management, good ore has been found on the 2300-ft. level. Statement of earnings of the various Knight companies during October shows that the Iron Blossom earned net \$51,000; Colorado, \$5500; Dragon Consolidated, \$2000; and Beck Tunnel, \$1600. This shows that the Iron Blossom is exceeding its present dividend requirements by \$53,000 per quarter.

#### SALT LAKE COUNTY

The Columbus Consolidated, Columbus Extension, Flagstaff Consolidated, and Superior Alta have been merged into a single company, the Wasatch Mines Co. It is proposed to drive a drainage adit and to extend the custom tramway so as to serve these mines. The Montana Bingham is shipping about 200 tons of ore per week, three-fourths of which is concentrated at the Winnemucca mill, and the force will shortly be increased. M. T. Miller is superintendent.

#### SUMMIT COUNTY

The *Park City Record* states that during the month of October the companies of that mining district shipped a total of 206 cars of ore, containing 7443 tons. Of this amount the Union Pacific Railroad Co. handled 5416 tons and the Denver & Rio Grande 2027 tons. The largest shipper was the Silver King Coalition, with 2632 tons of ore; the Daly-Judge was second, with 2196 tons; Daly West, 1470 tons; Grasselli company, 438 tons; Crother Ontario lease, 197 tons; E. J. Beggs, 51 tons; New York Bonanza, 57 tons; Barry-Coxe, 30 tons; and Charles Moore, 21 tons. Work on the new Ontario mill is at a standstill until the new roasters can be put into commission.

#### UTAH COUNTY

Plans are being made to equip the Santaquin King and Santaquin Chief mines with electrical machinery. Work on the construction of the 100-ton mill for the Rico-Welling-ton company is being pushed, and 12,000 tons of ore is said to be blocked out in the mine. The company will be \$100,000 in debt by the time the mill is finished.

#### WYOMING

##### ALBANY COUNTY

The Utopia Mining & Milling Co. is making arrangements whereby it will be able to resume work in the lower adit and open the orebody found last spring. An arrangement has been made with the Commercial mine, adjoining, for the use of electric power to operate a drill, and motor for ventilation. A fair quantity of ore has been opened in several adits 500 ft. above the main adit. Three properties in the Snowy Range district are ship-

ping ore, and others could be made profitable if a local plant were built. The Fram, Klondyke, and Cable are hauling ore to the railroad. Assays are said to have returned up to \$100 per ton in gold content. The North Park country is being boomed, and oil is being prospected by Denver people.

#### CANADA

##### BRITISH COLUMBIA

About a car of ore per month is being shipped from the Apex, which is two miles from New Denver, and returns show an average of 135 oz. of silver, \$4 to \$6 in gold, and 10% lead. At the Sunset, three miles from Sandon, a new adit is being driven at 1050-ft. level, which is 250 ft. below No. 7 adit. It is in nearly 1500 ft., and veins are frequently cut. It is expected that the ore-shoot in the upper workings will be cut within 200 ft. The end of the Vancouver Island coal miners' strike is said to be in sight. There is much excitement over placer ground at Keremeos, in the lower Similkameen, over placer ground. William Willis and associates have been prospecting with a Key-stone drill along the river for ten miles on each side of the boundary line at Chopaca, and if the results are satisfactory a dredge will be put at work.

Bruce White, one of the engineers of the Byron W. White Co., has located a group of claims near Crawford bay, which are stated to contain gold and platinum.

##### COBALT

At the Nipissing, sluicing has been finished near the low-grade mill, and the monitor is working close to the high-grade mill. The formation is Keewatin, and several veins have been uncovered, some showing calcite, cobalt, and a little silver. On No. 4 level of the Penn-Canadian, at a depth of 285 ft., the drift has entered a large calcite vein at the west end of the property. The metal content is low, since the vein is in the Keewatin formation. During the week ended November 9, eleven mines shipped a total of 602 tons of ore, and three mines shipped 44,992 oz. of bullion. Activity is increasing around the Elk Lake district and the railroad is expected to reach there by December 15. The Beacon Con. has its shaft down 200 feet.

##### DAWSON

Wood-cutters on the Yukon and Klondike have finished a busy season. F. Neill brought down 12,500 cords of wood, which was taken up Bonanza by the Klondike Mines railway and distributed at the Yukon Gold Co.'s thawing plants. This wood was sold for \$9 per cord. It comes from the Yukon and the Stewart, some as far as 150 miles above Dawson. An average of 20 cords per acre is cut. As it is used in mining, the wood is not subject to 'stumpage' or royalty of 50c. per cord imposed by the Canadian Government. The Yukon Gold Co. used about 35,000 cords last year at an average cost of \$13 per cord. Dawson used to burn 24,000 cords in the earlier times, and five or six years ago the quantity was 17,000 each winter. A considerable amount of coal is burned now.

#### MEXICO

##### SONORA

A rich body of ore averaging 5 or 6% copper has been found on the 800-ft. level of the Elisa mine of the Cananea Copper Co. In the Capote mine the orebody has been proved to continue to the 1000-ft. level. The new Capote shaft has reached a depth of 300 ft. and will be sunk to 1000 ft. The Moctezuma-Arizona is operating its 100-ton mill steadily, producing concentrate worth \$40 to \$100 per ton. A new unit will be added to the mill soon. Charles Schandelmeier has leased the West Cananea and is shipping 175 tons of 10% copper ore per month to the Cananea smelter. E. R. Arnold is preparing to ship ore from the El Pilar mine to the Cananea smelter. A. O. Koppes is in charge. Work has started on the Maria mine of the Carman Con. Co. and the 340-ft. shaft will be sunk to 500 ft. R. B. Phillips is manager. The 1400-ft. haulage and drainage adit of the Superior-Bonanza is practically completed, as is the 500-ft. shaft.

## Personal

Professional men are invited to send news of their engagements and travels. Such news is interesting to friends.

C. F. RAND has gone to Cuba.  
R. B. MCGINNIS is in Trinity county.  
M. W. VON BERNEWITZ is at Tonopah.  
H. P. HENDERSON is in San Francisco.  
ALFRED VON DER ROPP is in San Francisco.  
W. W. JOHNSON has returned from Alaska.  
J. R. FARRELL has returned to San Francisco.  
C. W. MERRILL has returned from New York.  
W. H. BLACKBURN was in San Francisco last week.  
FREDERICK BRADSHAW was in San Francisco Monday.  
A. SELWYN BROWN was at the Tom Reed mine recently.  
HOWLAND BANCROFT will leave New York for Venezuela Wednesday.

T. M. GIBSON is at Seattle and is expected in San Francisco.

WILLIAM BACH has gone to Siberia to report on gravel deposits.

HENRY C. MORRIS was in San Francisco this week on his way to Mexico.

EDWIN HIGGINS has joined the staff of the United States Bureau of Mines.

RELI KANDA is developing a newly discovered gold mine on Kyushu, Japan.

R. D. SALISBURY was in Buenos Ayres recently and has gone to Rio Janeiro.

W. G. WEBBER has returned from abroad and will live at Salt Lake City hereafter.

H. FOSTER BAIN will attend the American Mining Congress at Spokane next week.

T. BARNEY has gone to Siam to report on mines for Pearse, Kingston & Browne.

DESAIX B. MYERS will be in Mohave county, Arizona, till December 1, when he will return to Los Angeles.

JUAN FELIX BRANDES has returned to California after an absence of some months and is at San Diego.

ARTHUR J. HOSKIN has gone to Tallapoosa, Alabama, and Dahlonega, Georgia, to start cyanidation mills.

D. W. JESSUP is general superintendent for the Home Run Copper Co., in the Bristol district near Pioche, Nevada.

B. F. NOEHL has returned to Los Angeles after making examinations in Arizona and Nevada for New York people.

GERALD M. BROWNE is expected in London during the early part of November, returning from the United States, where he has been on a tour of inspection.

K. ASANO, chief metallurgist at the Ashio copper mines and inventor of the process used there for neutralizing smelter fume, will visit California in December.

F. L. RANSOME succeeds WALDEMAR LINDGREN as chief of the section of economic geology of the metalliferous deposits, for the United States Geological Survey.

FREDERICK K. BRUNTON has resigned from the testing department of the new reduction works at Anaconda, Montana, to accept a position as assistant superintendent at the British Columbia Copper Co.'s smelter at Greenwood, British Columbia.

C. DAVID WHITE has been appointed chief geologist of the United States Geological Survey in place of WALDEMAR LINDGREN, resigned to become Rogers professor of geology and head of the geological department of the Massachusetts Institute of Technology.

## Obituary

GREELEY FRENCH, an early pioneer of Nevada, died on November 7 at Silver City, Nevada, where he had resided for the past 38 years. He was born in New Hampshire in 1836 and came to California in 1859 and was among the first pioneers in the Carson valley. Later he turned his attention to ranching and politics, and was a well known figure in the life of western Nevada.

## Market Reports

### LOCAL METAL PRICES

San Francisco November 21.

Antimony .....	11-11½c	Quicksilver (bask) .....	41.50
Electrolytic Copper .....	18-18½c	Tin .....	52-53½c

## Company Reports

### TRANSVAAL GOLD MINING ESTATES, LTD.

This company was registered in the Transvaal in 1895 as the Lydenburg Mining Estates, Ltd., to acquire mining property in the Lydenburg district. The authorized capital is \$3,072,000, of which \$2,900,280 has been issued. There are also \$595,200 5% first-mortgage debentures, in bonds of \$480, \$96, and \$19.20 each. At the end of the financial year in 1911, its holdings comprised freehold farms with an area of 174,832 acres; mineral rights, 75,202 acres; and 989 mining claims of 155 by 413 ft. each, besides water-rights, etc. During the year ended March 31, 1912, the area was increased by 512 claims, and other property. An electric power station was built in 1911. The reduction plants consist of 75 stamps, 3 tube-mills, and cyanide plants at the Central, Elandsdrift, and Vaalhock mines. Gold recovered at the three mills, during the year, totaled \$1,910,000, and profit amounted to \$1,060,000, while other revenue was \$51,000. The Transvaal Government tax amounted to \$91,000, and debenture interest \$31,000. Dividends of \$820,000 were paid and \$384,000 was carried forward. In addition to the latter item there is \$130,000 remaining from the issue of debentures, of which, however, \$100,000 has been allotted to sundry items of further expenditure, including the Elandsdrift power-station, Peach Tree compressor plant, electrification of the Jubilee tramline, extension of crusher station, and a cyanide plant, which will give the central works a capacity of 13,000 tons per month.

### BECHUANALAND COPPER CO., LTD.

This company was formed in 1909 by the Bechuanaland Exploration Co. for the purpose of acquiring the Bushman and other claims, situated 120 miles southwest of Bulawayo, South Africa. The capital is £135,000 in 10s. shares, and the issue of 100,000 shares was underwritten by L. Hirsch & Co., E. J. P. Jorissen is consulting engineer, and B. F. McDowell is manager at the mine. The development of the deposit of copper ore was commenced a year ago, along the lines recommended by A. J. Fraser, engineer to the Consolidated Gold Fields. The report for the year ended May 31 shows that altogether 7760 ft. of development work has been done, of which 2548 ft. was done during the year. A number of lenticular orebodies have been disclosed, and it is intended to pay special attention to those between the first and second levels. Mr. McDowell reports that on the first level four separate lenses have a total length of 608 ft., averaging 40 in. wide and carrying 5 to 17% copper; while on the second level, seven lenses aggregate 597 ft. in length, averaging 50 in. wide, and carrying 9 to 23% copper. Development on the third level has been hindered by the irregularity of the orebodies. A shipment of ore has been sent to England to determine the best method of extraction.

### ARIZONA COPPER CO., LTD.

This company was formed in 1884 and has an issued capital of £703,985. It owns the Longfellow and Metcalf groups of copper mines, a smelter at Clifton, Arizona, and a railway serving the district. The half-yearly interim report for the six months ended March 31 shows a production equal to 9073 short tons of bessemer copper. The profit from the mine was £150,596, and £36,351 was received from the railway. Out of this £2733 has been paid as interest on debentures, £7767 as income tax, and £12,265 as dividend on the preference shares. The ordinary shares receive £94,993, being at the rate of 25% on 1,519,896 shares of 5s. each, and £69,187 is carried forward. This year £500,000 new debentures were issued for the purpose of raising the capital required for increasing the output, extending the dressing plant, and rebuilding the smelter. L. D. Ricketts has charge of the design and construction of the new plant, which will have roasters of the Herreshoff air-cooled type, three 12-ft. converters of the Great Falls type, and a stack 300 ft. high and 22 ft. diameter at the base.

## James Lewis & Son's Copper Report

Copper has been under the influence of the great depreciation of securities on the European and American Stock Exchanges caused by the outbreak of war in the Balkans. After fluctuating between £78 17s. 6d. and £76 17s. 6d. cash, standard copper had a sharp fall to £72 2s. 6d. on October 14, but rapidly recovered to £77 5s. on October 16, subsequently declining to £74 2s. 6d. on October 22 and advancing to £76 8s. 9d. next day, only to fall again to £74 15s. on October 30. Closing prices on November 1 were £75 7s. 6d. cash and £76 three months prompt. Sales have amounted to about 57,000 tons. There has been but a very moderate demand for refined copper, manufacturers buying only for their immediate requirements. American refiners have sold but little electrolytic, of which sales have been made at 17¼ to 17¾c., though the larger producers still hold for 17¾c. per pound. The present needs of American consumers appear to be covered by contracts still in force.

American shipments to Europe are advised as 24,670 tons for the past month. In view of this, a further considerable addition to the stocks held by refiners at the end of the month may be looked for, and, with the increased cost of holding them, due to dear money, there will be more desire to realize. European stocks have decreased 2529 tons, and the visible supply 1604 tons during the month. Imports are 310 tons and deliveries 7388 tons less than during the same period last year. The total arrivals in England and France for the month have been 17,188 tons and the deliveries 19,021 tons fine. The arrivals in England from Chile during the month have been 1475 and the deliveries 1451 tons fine, and from other countries 10,664 and 11,860 tons fine, respectively. The arrivals here and in Swansea from the United States have been 1872 tons bars, etc., 405 tons plates, etc., and 35 tons matte, equal to about 2276 tons fine copper, in London 510, and in France 4304 tons fine. The Chile charters for the month are advised as 3800 tons, including 2050 tons for the United States.

Quotations November 1: Standard, £75 7s. 6d. for cash and £76 three months' prompt; English best selected ingots, £80 10s. to £81 10s.; and tough cake, £80 10s. to £81 10s. per ton, less 2½% delivered Birmingham. Electrolytic wire bars, £80 10s. to £81 net cash c.i.f.; 13s. 6d. to 13s. 9d. for ore of 20%, and 14s. to 14s. 3d. per unit for Chile regulus or American matte free from silver.

MEASUREMENT IN SACRAMENTO RIVER BASIN. By H. D. McGlashan and F. F. Henshaw, under the direction of J. C. Hoyt. Water-Supply Paper 298. 411 pages.

## Book Reviews

Any of the books noticed in this column are for sale by, or can be procured from, the MINING AND SCIENTIFIC PRESS.

INDUSTRIAL CHEMISTRY FOR THE STUDENT AND MANUFACTURER. Edited by Allen Rogers and A. B. Aubert. 854 pp.; ill. D. Van Nostrand & Co., New York, 1912. For sale by the *Mining and Scientific Press*. Price \$5.

GENERAL AND INDUSTRIAL CHEMISTRY. By Ettore Molinari; translated by Ernest Feilmann. 704 pp.; ill. P. Blakiston's Son & Co., Philadelphia, 1912. For sale by the *Mining and Scientific Press*. Price \$6.

When two books upon the same topic and of approximately the same size appear simultaneously, it is natural to compare them, even though, as in this case, some injustice is thereby done to one volume. The forty-three chapters of the first volume have each been prepared by a specialist, many of whom have attained considerable distinction in the special field of which they have written. The second volume has been prepared by Mr. Molinari for the use of his classes at the Commercial University Luigi Boeconi at Milan, and is really two books in one, since the first part deals with general inorganic chemistry, followed by a discussion of inorganic industrial chemistry. Probably there is a field for such a work in Italian, and there is even some field for it in English, since the convenience for reference of having the whole subject of inorganic chemistry covered in one volume is considerable. Considering that the book has been translated from Italian into English by a German, its style is good, but its chemistry is so faulty as to greatly decrease its usefulness. Even in the part devoted to general chemistry the translator has corrected a number of erroneous statements occurring in the original, but since both author and translator are evidently unfamiliar with metallurgical chemistry, beyond the scope of European practice, the discussion of the recovery of gold, silver, copper, iron, and the other principle metals is so faulty from a general standpoint as to be almost useless except to one interested to know how these processes have been modified when worked on a limited scale in Europe. Italy is, for a European country, fairly well provided with mineral deposits, and has a notable place in the field of chemical engineering. As a survey of Italian practice this book will be of great interest, but it should only be used with caution by the general reader.

An adequate review of the volume edited by Messrs. Rogers and Aubert could only be written by C. F. Chandler or some one of similar attainment. The thirty-four collaborators who have aided the editors in the preparation of the book are all men entitled to speak with authority, and they have summarized the most recent American practice in the whole field of chemical engineering, even a chapter on laundering being included. A need for such a volume has long existed. Wagner's 'Chemical Technology' has long been out of date; the same may be said of the texts by Groves and Thorp. The excellent little volume of F. H. Thorp, though fairly recent and admirable as a text-book, is too brief for general reference, while the dictionary of applied chemistry by T. E. Thorpe is too expensive for the ordinary chemist. The text-book by F. H. Thorp is the only one written from the standpoint of American practice. The policy of the publishers in selling this volume at such a low price as to put it within the reach of all, cannot be too highly commended, and is likely to receive its reward in a correspondingly large sale for the book. Chemical engineering has some bearing on almost every form of industrial activity, and the number of those who will be grateful for the rendering available of so authoritative, concise, and cheap a work of reference is exceedingly large.

T. T. R.

## Concentrates

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

'GOB' is a term used to signify waste left in the rooms or abandoned workings of coal mines.

TUBE-MILLS numbering 285, using a total of 27,511 hp., equal to 96.5 hp. each, were in operation at the end of 1911.

EMPLOYMENT of relatives by mine officials is a bad practice, and does not spell economy in any part of the world.

APPLICATION of graphite paint to the steel lining of a shaft in Wyoming has protected it from the action of acid water.

MACHINERY in the Transvaal mines, excluding 3157 motors of 179,947 hp. using purchased power, has a total of 590,590 horse-power.

COLLODION is recommended as a good material for restoring the surface of tracing cloth after erasing. It can be applied with a camel's hair or sable brush.

MEN employed in the different metal industries in Germany total 120,701, who average 94c. per day when paid by hours worked, and \$1.26 when paid by piece-work.

BLASTING by electricity has not met with favor, and is not in use on the Kalgoorlie goldfield, and in instances where it has been tried it was found that holes frequently missed fire.

ACRE-FOOT is equivalent to 43,560 cu. ft., and is the quantity required to cover an acre to the depth of one foot. It is commonly used in connection with storage for irrigation work.

CRUDE-OIL production at Baku, Russia, in 1911, amounted to 6,870,967 tons, and shipments of illuminating, lubricating oils, and liquid fuel, were 1,370,966, 303,225, and 3,883,063 tons respectively.

ICE WATER supplied to men in hot mine workings is beneficial and increases efficiency. This has been proved at the Butte and Comstock mines. The men must only drink small quantities and at once return to work.

LUBRICATION is the life of a moving mechanical part. If you neglect this important attention to machinery, or do it on a hit-or-miss principle, you pay for it by broken parts, shut-downs, and other kindred troubles.

BALL BEARINGS on line shafting and other machinery show a large reduction in friction losses. A trial is to be made at the Perseverance mill, at Kalgoorlie, in fitting a No. 8 Krupp ball-mill with these bearings.

PAPER-PULP MILLS of Sweden require 72,800 tons of sulphur yearly, nearly all of which is imported from Sicily at a cost of \$25 per ton at Baltic ports. Several years ago the question of importing American sulphur into Sweden was investigated; but nothing was done, owing to inability to solve the freight charges.

DETONATORS at the Panama Canal were found to be inefficient from two causes: (1) absorption of moisture, and (2) non-uniformity of detonator current explosive values. Investigations showed that the heavy charging of

holes and condition of work often required detonators to be left in charged holes for 24 hours or more. It was discovered that some brands of detonators, after being immersed under varying heads of water for these periods, became saturated and the fulminate ruined. Others were not affected so much, but nearly all brands were found to absorb water. Three of the best brands made in the United States and one in Germany were tested under heads of 25 and 40 ft., and none was found impervious after immersion from 24 to 36 hours. Tests at the Ancon laboratory showed that deterioration was not due to free acids, as had been supposed, but primarily to composition and construction of the exploder itself. Manufacturers then supplied them impervious to heads of 40 to 60 ft. In one brand a cement plug is inserted just above the loose fulminate and at the point where shell deterioration had occurred. Above the plug a black viscous compound is inserted, and above this again the usual sulphur plug is put in as a cap. The other brand supplied is composed of a double jacket or shell, the inner one containing the fulminate at the bottom, a small quantity of gun cotton, the bridge, and usual sulphur plug. This shell is fitted with the outer one, which is filled with a black compound completely surrounding the former. If the inner shell is deteriorated by sulphur action, the outer one and compound will prevent moisture reaching the fulminate.

## Decisions Relating to Mining

Specially reported for the MINING AND SCIENTIFIC PRESS.

### MINING COMPANIES—CONTRACTS

Where an attorney made a contract for services with a mining company, payment for which was, under the terms of the contract, to be made out of the proceeds of any sale of the mine, or if no sale be made, out of the net proceeds, from operation, not exceeding 10% thereof monthly, the contract limits the sources from which the attorney can compel payment to such proceeds or profits.

*Lunch v. Keystone Consolidated Mining Co., (California)* 126 Pacific, 968. October 18, 1912.

### MINING CONTRACTS—REMEDY FOR BREACH

Where under an oral agreement that they were to receive a written lease for a term of years, the lessees of mining property took possession of it with the consent of the lessor and enter upon its operation, upon the refusal of the lessor to execute such lease, they may waive their right to specific performance, surrender the property, and recover in an action for breach of contract whatever reasonable expenditures they have made in preparation or taking out ore.

*Rains v. Schermerhorn, (Kansas)* 126 Pacific, 1085. October 12, 1912.

### RE-LOCATIONS—PRIORITIES UNDER

Where the patent survey of a junior location was made prior to the patent survey of a senior location and the boundaries were corrected, in conformity with the calls of the location certificate, if a conflict is found with the surface covered by the senior location the lode line of which has been marked in the manner prescribed by law, the senior locator takes the conflict area. The failure on his part to file an amended location certificate with the recorder, prior to the patent survey does not invalidate the senior location, but merely puts the burden of proof upon the senior locator.

Where a claim is re-located so as to exclude prior patented ground, and in making such re-location, the claim owner takes in new ground, he in effect makes a new location and loses his priority under the former location.

*Indiana-Nevada Mining Co. v. Gold Hills Mining & Milling Co., (Nevada)* 126 Pacific, 965. October 7, 1912.

## Commercial Paragraphs

The Braden Copper Co. of Chile has given the HARDINGE CONICAL MILL Co. an additional and repeat order for twelve more 8-ft. Hardinge pebble mills, making a total of sixteen now on hand or on order for this company. The Teziutlan Copper Co. has placed an order for four similar sized Hardinge mills. These mills are for semi-fine grinding, that is, to pass about 60 mesh.

J. W. STONEHOUSE, Victor, Colorado, reports sales of his patent enamel mine bell signals to many mines. These signs have a metal base and the codes are printed in enamel, the lettering being in white upon a dark blue ground. The signs are made to suit the laws and codes of the various states or any local requirement. Full information, with a large list of mines already supplied, will be furnished by the manufacturer.

THE TAYLOR IRON & STEEL Co. announces the acquisition of the Wm. Wharton Jr. & Co., Inc., of Philadelphia, Pennsylvania, with works at Philadelphia and Jenkintown, Pennsylvania, and its subsidiary corporation, the Philadelphia Roll & Machine Co. The Taylor company and the Wharton company have both had a successful history of more than fifty years. During the past eighteen years the business of each company has been largely supplemental to the other in the manufacture and application of manganese steel.

THE C. O. BARTLETT & SNOW COMPANY OF CANADA, LTD., has been granted a Dominion Charter to deal in, manufacture, and install elevating and conveying machinery, power transmission machinery, engines, boilers, hoisting machinery, brick machinery, garbage reduction and destruction machinery, paint machinery, grain and cereal machinery, and to carry on a general line of engineering, manufacturing, and construction work. The head office of the company has been opened at 282 St. Catherine street, Montreal, with Herbert S. Hershey as general manager. This company is the outgrowth of the extensive Canadian business of the C. O. Bartlett & Snow Co. of Cleveland, Ohio, and although the connection between the Ohio company and the Canadian company will be very close for some time, the organization and management are entirely independent.

The remarkable properties of vanadium iron render it a peculiarly suitable substitute for common gray iron in castings subjected to heavy stresses. Tests have shown that vanadium tungsten iron has nearly three times the tensile strength of ordinary cast iron. It is, besides, remarkable for density of grain and hardness, hence it is almost impossible to break it by any ordinary means. It is an ideal metal for certain parts of rock-drills, such as the cylinder, chest, and air-heads, and the use of this metal in the Wood rock drills, made by the WOOD DRILL WORKS, of Paterson, New Jersey, accounts in a measure for the high efficiency and economy of these drills. They are strongest where most drills are weakest, hence are much less liable to suffer the accidents and breakdowns common in other drills. The use of vanadium tungsten iron in Wood rock drills marks a distinct advance in rock-drill construction.

THE TRAYLOR ENGINEERING Co., 30 Church St., New York, advise that they have had a great revival in business and that their works are now operating at their full capacity. Among recent orders are the following: Granby Con. Mining, Smelting & Power Co., carload of water jackets; C. H. Ziegenfuss, complete crushing plant, consisting of crushers, screens, and elevator; Consolidated Mining, Smelting & Power Co., of Canada, one set of 42 by 16-in. 'AA' heavy-duty rolls; Miami Copper Co., six sets of 42 by 16-in. 'AA' rolls; El Rayo Mining & Development Co., one set of 30 by 14-in. and one set of 36 by 16-in. 'A' rolls; Stanwood Construction Co., three sets of 30 by 16-in. 'A' rolls; Cia. Minera Nazareno, two sets of 18 by 10-in. 'A' rolls, two sets of 9 by 10-in. 'B' rolls, and two sets of 7 by 10-in. Blake crushers; McIntyre Porcupine Mines, Ltd., complete 150-ton cyanide plant, consisting of rolls, tube-mills, Chilean mills, agitators, thickeners, classifiers, and a Traylor duplex continu-

ous vacuum slime filter; Doe Run Lead Co., three sets of 42 by 18-in. 'AA' rolls; Teziutlan Copper Co., one set of 42 by 16-in. 'AA' rolls; Ducktown Sulphur, Copper, Iron & Mining Co., carload of water jackets; Balbach Smelting & Refining Co., complete equipment for doubling the capacity of the present smelting furnace; American Smelting & Refining Co.'s East Helena plant, 14 water jackets; Whitehall Portland Cement Co., one No. 7½ gyratory crusher; U. S. Gypsum Co., crushing plant, consisting of 60 by 24-in. screen and No. 7½ gyratory crusher; White & Bros., complete 100-ton copper smelting plant; Kennicott Mines Co., two 48 by 12-in. screens; U. S. Assay Office, complete grinding plant, consisting of crushers and 6-ft. improved Chilean mill; John Wunder, 20 by 24-in. Blake jaw-crusher, fitted with water-cooled bearings; Tacoma Smelting Co., two 15 by 24-in. Blake crushers, and two 24 by 36-in. Blake crushers; Mason Valley Mines Co., two carloads of water jackets. Wm. P. McGary, complete 100-ton rock-crushing plant.

## Catalogues Received

A. LESCHEN & SONS ROPE Co., St. Louis, Missouri. House organ, 'Leschen's Hercules' for August and September.

T. H. PROSKE, Denver, Colorado. Catalogue of 'Imperial' Drill Sharpening Machine. 16 pages. Illustrated. 5 by 7 inches.

DODGE MFG. Co., Mishawaka, Indiana. Catalogue 106A-12, 'Power Transmission Machinery.' 48 pages. Illustrated. 6 by 9 inches.

LUMEN BEARING Co., Buffalo, New York. Booklet giving details of various alloys made by the firm. 9 pages. 3½ by 6 inches.

MCKIERNAN-TERRY DRILL Co., 115 Broadway, New York. Bulletin on 'Busy Bee' Hammer Drills. 16 pages. Illustrated. 6 by 9 inches.

CHICAGO PNEUMATIC TOOL Co., Chicago. Bulletin No. 121, 'Pneumatic Rammers and Foundry Equipment.' 8 pages. Illustrated. 6 by 9 inches.

MINE & SMELTER SUPPLY Co., 42 Broadway, New York. Bulletin No. 25, 'The No. 6 Wilfley Concentrator.' 20 pages. Illustrated. 7 by 10 inches.

EDGAR ALLEN AMERICAN MANGANESE STEEL Co. Bulletin No. 51, 'Missabe Dippers for Steam Shovels and Dipper Dredges.' 16 pages. Illustrated. 6 by 9 inches.

ALBERGER PUMP & CONDENSER Co., 140 Cedar St., New York. Booklet, 'Why,' describing Alberger boiler feed pumps. 12 pages. Illustrated. 3½ by 6 inches.

BYRON JACKSON IRON WORKS, 357 Market St., San Francisco. Bulletin No. 45, 'Jackson 1912 Direct Connected Centrifugal Pumps.' 24 pages. Illustrated. 6 by 9 inches.

DENVER ENGINEERING WORKS, Denver, Colorado. Bulletin No. 1056, 'Blake Ore Crushers,' 8 pages. Bulletin No. 1057, 'Mine Timber Framing Machinery,' 16 pages. Illustrated. 8 by 10 inches.

CONNERSVILLE BLOWER Co., Connersville, Indiana. Catalogue No. 11, 'Smelter Blowers.' 32 pages. Illustrated. 12 by 9 inches. Also bulletins and booklets on rotary vacuum pump, jet condensers, blowers, etc.

INGERSOLL-RAND Co., 11 Broadway, New York. Form No. 4023, 'Temple-Ingersoll Electric-Air Rock Drill,' Type 4-E. Form No. 4025, Type 6-F. Accompanied by Form No. 4209, descriptive of same drills.

DENVER FIRE CLAY Co., Denver, Colorado. 1913 Catalogue of Assayers' and Chemists' Supplies, and Scientific Apparatus. 530 pages. Illustrated. 8 by 11 inches. Also Catalogue A, 'Donaldson Tilting Crucible Furnace.' 12 pages. Illustrated. 6 by 9 inches.

SULLIVAN MACHINERY Co., Chicago. Bulletin No. 58-N, 'Sullivan Small Air Compressors,' 16 pages. Bulletin No. 58-O, 'Sullivan Portable Drilling Rigs,' 16 pages. Bulletin No. 66-B, second edition, 'Sullivan Rock Drill Mountings and Accessories,' 32 pages. All illustrated. 6 by 9 inches.

## EDITORIAL

**I**NCREASE in the public ownership of public utilities is strikingly evidenced in a recent German estimate that 30 per cent of the total railroad mileage of the world is state owned.

**T**HE recent decision that the exhaustion of ore reserves does not depreciate the value of a mine is now supported by court testimony. In the case of the Silver King Consolidated Mining Company v. Silver King Coalition Mining Company, Mr. Solon Spiro testified that four and a half years' work, entailing an expenditure of \$127,000, yielding \$23,000, and leaving the claim with no ore developed that would pay for its extraction, had enhanced the value of the property!

**U**MEGAKA MARU, 'the odor of plum blossoms,' carries pleasant memories to many Americans. A fast naval auxiliary built by popular subscription during the Japanese-Russian war, this trim and comfortable steamer served in times of peace to carry passengers from Shimonoseki to Fusan. From this service she was detailed a year ago to carry the American mining engineers, visiting Japan, through the Inland sea, and none who enjoyed that trip will forget the comfort and pleasure afforded the travelers by their temporary home. In a recent storm the ship was wrecked and sank near Moji, ending a useful career fortunately through an accident of peace, rather than being destroyed gloriously but futilely in war.

**P**ROTEST is being made by Mr. W. R. Burdett over the action of the General Land Office in allowing patent to the Oxford and Gerold claims in Little Cottonwood canyon, pending a hearing before the local Land Office of a protest based on the alleged including by the claimant in his application for patent of work done long prior to his own location. It is now necessary to take the matter up with the Attorney General, and Mr. Burdett is involved in much additional expense. We know nothing of the merits of this case, but cite it as one of the sort that generates friction between the public and the Department of the Interior. It would seem that when the time for hearing a protest had been set by the local Land Office, a patent should hardly have been issued pending the hearing.

**W**HAT constitutes a public use, is a live question in Colorado, where the voters have apparently adopted a constitutional amendment designed to bring the 'smelter trust,' as orators there like to call the American Smelting & Refining Company, under jurisdiction of a public service commission. The wording of the amendment is so broad as to include all companies, associations, or corporations, engaged in "smelting, sampling, refining, reducing, milling, or otherwise treating ores, minerals, or metals." This may involve serious consequences for every milling company in Colorado, whether engaged in custom work or not. On the other hand, the corporation at which the amendment was aimed, can easily transfer the bulk of its business to other states. It is also, in the opinion of attorneys, still a question of fact whether an institution is a public utility, regardless of the amendment. Altogether the mat-

ter seems badly tangled at present. It is to be remembered that there would be substantial advantage as well as disadvantage if the whole mining and metallurgical industry was held to be a public utility. It would be pleasant and often economical to have the right to condemn land for a shaft or smelter, to mention only one such advantage. Furthermore, the good or harm flowing from the amendment just adopted will depend upon subsequent legislation and commission decrees.

**S**ILVERTON, that most attractive mining city in the San Juan district of Colorado, is to have a new customs concentrator for the treatment of complex zinc ores. At present such ores yield but slight return because they are not properly dressed before shipment. With Mr. James M. McClave as engineer and the backing of the Silverton Commercial Club, a plant well suited to meet local conditions should result. To our way of thinking, this is much better than the building of a local experimental plant by the general government. What Silverton needs is facilities for producing commercial results with known process. The smaller amounts of ore needed for experimental work to discover new methods of treatment had much better be sent to the excellent plant at the Colorado School of Mines at Golden or the newly established laboratory of the Bureau of Mines at Denver. After methods have been formulated is time enough for the building of local plants, and even then, to get results, organization on a commercial basis is preferable. The disposition of Silverton's citizens to help themselves is a true expression of Western spirit at its best.

**D**IAMONDS have been found in Brazil since 1729, and for over a century and a half that country held first rank for diamond production. Bahia is even now a most important source of black diamonds such as are widely used in drilling, and at Bagagem and Agua Suja in Minas Geraes alluvial deposits yielding white stones of excellent quality are worked. In the last few years serious efforts have been made to interest capitalists in the United States in the development of these diamond fields, but the work has by no means been always well advised or even honestly conducted. The district attorney at New York is now investigating Mr. W. C. Meyer, who has been active in promoting diamond-mining companies in the United States, Canada, and England. An examination of one of the properties made by Mr. Louis S. Noble developed the fact that the total value of the gravel that it was proposed to work was about five cents per cubic yard, including in the estimate gold, platinum, and diamonds. In promoting this property a photograph of one of the dredges working at Oroville is said to have been represented to be that of a diamond-digging dredge at Jequitinhonha.

### Constitution of the Institute

Elsewhere we print in full the Constitution and By-Laws recommended by the committee, Messrs. J. W. Richards, Charles Kirchhoff, and C. F. Rand, appointed at the Institute meeting on October 7 to consider the revision of the present fundamental documents of the Institute. It will be noticed that the provision for creation of a group of Fellows has been made as a separate amendment, so that discussion of this proposal may not interfere with acceptance of the documents as a whole. This and other features of the report of the committee are suggestive of comment for which this week we have no space, regular departments having been ruthlessly curtailed to make room for the full text of the report. We must add, however, that the principal change has already been carried into

effect, since in the opinion of legal counsel, the action taken at the meeting in New York on October 7 and at Cleveland on October 30 was sufficient to authorize the present board of directors to increase the number of directors from nine to twenty-four. At the meeting held in New York November 12 a resolution was passed instructing the board to make the change, to be effective in February next. This removes from the realm of discussion the most important matter on which any difference of opinion has existed, and indicates that progress will henceforth be both rapid and effective. The names of ten new directors for election in February will be proposed by the committee on nominations, of which Mr. P. N. Moore is chairman, but the office of secretary will be filled by the board of directors, in anticipation of the adoption of the revised Constitution and By-Laws.

### California Miners and Minerals

The meeting of the California Miners' Association in this city on December 9, 10, and 11 is an opportunity for effective action that should not be allowed to pass unutilized. The Association has been effective for good ever since its formation twenty years ago. At that time the situation was such that the future of the mining industry in this state seemed seriously threatened. County associations of miners, commercial bodies throughout the state, the Chamber of Commerce and the Board of Trade of San Francisco, and other organizations united in effective action which resulted in securing the passage of the Caminetti Act and other useful legislation. During the years that followed, the Association labored to further the interests of the whole mining industry of the state and accomplished much good, but more recently interest in the Association has flagged for the lack of a vital issue around which to rally support. Now there is no lack of one. Workmen's compensation legislation and the conservation policy, in its relation to mining, are of present importance and interest, but above all, plans and construction are already well advanced for the Panama-Pacific International Exposition, to be held in this city in 1915. Intended as it is to further the development of industry and trade on the Pacific Coast, its keynote must be natural resources. In an exposition held in the golden city by the Golden Gate, in the golden state of California, known for the gold of its rivers and mines, the gold of its sunshine, and its golden orange groves, it is inevitable that gold shall be the dominant note. But the wealth of California lies not in gold alone, but in a variety of other products which, though less potent to allure, are yet none the less important as sources of profit and progress. The mineral exhibit at our exposition in 1915 should surpass any ever gathered together at an exposition. For this we have the necessary materials and facilities, and if the final result shall be less than may rightfully be expected of us, it will be because the necessary efforts were not made, and made soon enough. The time remaining before the opening of the Exposition is not great, and the gathering together and arranging of a mineral exhibit is a tedious task. We urge the fullest coöperation of everyone interested, not only in the mineral industry of this state, but of all interested in the development of the West, for the fundamental character of the mineral industry makes it of importance even to those whose activities have no apparent contact with it. What a few cannot do, even with much effort, can easily be done by all working in harmony. The wind seems light upon a sailor's finger, but on the sails it exerts a pressure that speeds the ship along. Let everybody push, even if only a little.

## Revision of the Mineral Land Laws

The report of the committee of the American Mining Congress on general revision of the mineral land laws, presented at Spokane this week by the chairman, E. B. Kirby, is summarized below:

### THE REPORT

The committee reports that it was unable to secure any action by Congress at the past session toward a general revision of the land laws. What was within the ability of the committee has been done. There has been much correspondence, and its chairman has personally made three visits to Washington. Two attempts were made to interest the Administration in the proposed measure, and it was also presented to the chairman of the Committee on Mining and the Committee on Public Lands in the Senate and House, but without result. Reed Smoot, senator from Utah, who is chairman of the Senate Committee on Public Lands, approves the measure, made genuine efforts to assist the committee, and went with its chairman to W. L. Fisher, Secretary of the Interior, to ascertain whether the Administration would not take up the revision as part of its program. The Secretary declared himself in favor of correcting certain special points such as the apex law and the unlimited number of locations. He did not then decide whether to take up a general revision, but has since done nothing in the matter, except to recommend the abolition of the apex law in Alaska, and it is evident that the attempt to show him the impracticability of patchwork revision was unsuccessful. On inquiry in the Senate, an unexpected opposition developed on the part of a certain senator who was opposed to any change in the laws. Mr. Smoot was therefore obliged to drop the matter, explaining that with his overwhelming burden of work he could not undertake to push a measure against opposition in the Senate unless the Administration supported it. In the House no one was found willing to undertake the laborious work involved without first knowing that the measure would be successful in the Senate. (It may be added that the opposing senator will not appear in the next Senate.)

This experience has made several points clear:

1. The plan of the American Mining Congress for a general revision is universally approved as soon as it is understood. It is now evident that it will have no opposition except that small percentage which always appears when anything new is proposed and which usually comes from extreme conservatives, who are by nature opposed to any improvement in existing laws. It is indifference and not opposition which must be overcome in order to secure the revision.

2. No measure of reform which is not widely known and understood can be carried through unless it is steadily pushed by some active aggressive men. Legislators are like other men, unwilling to move in a business which they do not understand, and only a very small percentage of the hundreds of individuals at Washington who have to act in the matter are familiar with mining laws or their effects. To make the situation clear enough to induce action there must be long persistent work by some one on the spot.

3. This must be done by the American Mining Congress itself. No legislator will do such trying work unless he is keenly interested in the subject. The men with initiative enough to undertake such things are soon overloaded, and it would take a prolonged search to find and interest some senator or representative who was willing and also free to undertake it. It will therefore be necessary for the American Mining Congress to follow the same procedure that was required in creating the Mining Bureau. It must have a representative at Washington pressing the revision measure. While the secretary of the American Mining Congress was there during the last session he was too much overloaded with other matters to undertake the revision business. It is necessary to face the fact that the American

Mining Congress cannot secure revision or any other relief for mining unless it provides enough money to do the work required at Washington, and this committee is unable to proceed further until some effective means are provided for following up its efforts.

The attached memorandum was submitted with the report. In it are summarized the chief reasons for urging a general revision.

### IMPERFECTIONS OF THE PRESENT LAWS

The mineral land laws of the United States and Alaska, framed in 1872 and interwoven with a mass of supplementary state legislation, differing in every state, fail to meet the present requirements of the industry. Moreover they have developed various evils the injurious effects of which are steadily increasing. These have become so serious as to retard the development of mining and to create dissatisfaction and complaint everywhere.

At every annual session of the American Mining Congress during the past twelve years the prevailing discontent with the present code has been voiced by various resolutions calling attention to its evils and asking for the correction of this or that feature of the laws relating to mineral claims located upon the public domain. Such complaints steadily increasing in volume have found expression not only in the Mining Congress but also in the press of the mining communities, all the mining journals, in the societies of mining engineers, and, in fact, through every medium available for the expression of public sentiment. They have nevertheless been without result for the reason that the mining laws are largely interdependent and it is difficult if not impossible to correct one fault without straightening out the entire code. Moreover, the states affected, some of which have often attempted to make improvements, find that nothing effective can be done without the action of Congress. In short, patchwork is impossible and a general revision is necessary.

### DIFFICULTIES OF THE WORK

Since the problems involved in the work are peculiar to the industry and are unusually difficult, it is evident that their satisfactory solution will require the aid of the most experienced judgment together with a free and direct expression of views by the mining communities themselves. Among the many questions which will arise during a revision are the following, which will illustrate the nature of the work.

### SOME OF THE PROBLEMS

The apex law is responsible for many uncertainties of title and much litigation is caused by it. The latter includes not only the conflicts caused by the extralateral right, but also those occasioned by the consequent shapes of claims and the overlapping of lines. The creation of a definite procedure for acquiring rights to those claims in which the mineral is not near the surface and where discovery must in consequence be long deferred, is badly needed. Tunnel locations and the uncertainties of title caused by them in neighboring claims, must be adjusted. The present non-observance of the law of discovery is a grave matter. The partial or complete non-observance through various expedients of the law of assessment is an open scandal. The location of an unlimited number of claims by one individual is wrong and should be stopped, as should locations by proxy.

### REASONS FOR REVISION NOW

A general revision now will be particularly timely because of the public interest in conservation and the new legislation now under consideration, for timber, oil, phosphate, and coal lands, and also power-sites. To omit the mining code from any program for the betterment of laws relating to natural resources would be to pass by the field where relief is most urgently needed.

### THE ACTION REQUESTED

The American Mining Congress at its last annual session therefore reached the following decision:

That Congress be asked to undertake promptly a general

revision of the mineral land laws, which, in view of the difficult problems presented, should be in coöperation with the mining industry. The plan adopted for this coöperation should give all sections opportunity for public hearing and the discussion of remedies. The Mining Congress will suggest a practical plan for this purpose later on if desired.

In requesting action upon this matter it is therefore suggested that if Congress will authorize a committee to act, the representatives of the American Mining Congress will be pleased to furnish such detailed information and suggestions as may aid the committee in preparing a plan, whether for a commission or otherwise, which will accomplish the ends desired. A joint resolution like the following is suggested:

That ——— committee ——— is instructed to prepare and submit at this session a mode of procedure whereby Congress may undertake a general revision of the mineral land laws of the United States in the way which will best promote the public welfare and meet the peculiar needs of the mining industry. The plan recommended should provide a practical means whereby Congress may utilize the best experience and judgment available in the industry and which will give the mining regions of the United States and Alaska ample opportunity for public hearings and the discussion of remedies.

After Congress has empowered a committee to act, the committee of the American Mining Congress hopes to have the opportunity of presenting to the committee at Washington such detailed information and suggestions as may aid in preparing a plan whether for a commission or otherwise, which will be satisfactory to Congress and accomplish the ends desired. It is believed that this may be secured through a wisely selected commission, authorized to draft a revised code for the use of Congress. This commission should hold public hearings in the principal mining centres of the West and Alaska. It should call before it men prominent for their knowledge of prospecting, of claim locations, of mine operating, mine litigation, and the history of mining laws, and should invite opinions from the public bearing upon the specific points at issue. The authorities and experience of other mining countries should also be consulted and made public and the final recommendations of the commission should be presented to Congress in the form of a full drafted code.

It is clear that there is a best practical solution for each one of the difficult problems involved in a general revision of the mineral land laws, but in order to determine these best solutions all opinions must be brought to a focus before some authoritative body which has the power of decision. Moreover, in order to assure the general approval and acceptance of reforms affecting so many varied interests, the personnel of this body should be such as to command confidence, and the mining communities should have full opportunities to present their views before it. There is a wealth of learning and practical experience in the country, which is available for the work of framing a revised code, but it is distributed among many men and must be focused by the plan indicated.

ORE production of Silesia in 1910 and 1911, was, respectively, in metric tons: iron ore, 251,000 and 181,000; zinc ore, 591,000 and 572,000; and lead ore, 55,000 and 48,000. The following table shows the falling off in the iron-ore production in Upper Silesia since 1900:

Year.	Metric tons.	Year.	Metric tons.
1900 .....	406,839	1906 .....	244,863
1901 .....	457,126	1907 .....	282,515
1902 .....	428,132	1908 .....	263,745
1903 .....	369,189	1909 .....	233,368
1904 .....	337,396	1910 .....	233,823
1905 .....	314,955	1911 .....	150,197

The flooding of the Bibiella mine was the principal cause of last year's sudden drop; and as several leased mines are working without profit and only because of their contract obligations, the production is expected to remain low in the near future. On the other hand, the consumption of iron ore in Upper Silesia has exceeded 1,000,000 tons in each of these years, amounting to 1,112,120 tons in 1910

and to 1,120,213 tons in 1911. There is a good demand for all sorts of foreign ores in the province. Upper Silesia makes from galmei and zincblende about 150,000 tons of raw zinc, which is about 65% of the production of Germany, and Germany produces a large percentage of the world's supply of raw zinc.

## Electrolytic Copper Extraction in Norway

By CHARLES ADAMS HOLDER

For several months a company at Aamdal, Norway, has been successfully extracting copper from the crude ore by an electrolytic process invented by Victor Hybinette, a Norwegian engineer, who has patented the process in Europe and the United States. The Aamdal works have proved so successful that plants are now under way for increasing the output to 3 tons of metallic copper per day. The treatment consists in leaching the crushed ore with a dilute solution of sulphuric acid, which dissolves out the copper; the copper sulphate solution is then electrolyzed and the copper precipitated. Experiments with copper pyrite from the Orkla and Sulitjelma mines, in which much foreign capital is invested, have been equally successful, and as a result these ores will probably be treated by the Hybinette process in the future. The ores were formerly shipped to Germany and Sweden, respectively, owing to their refractory character and to the lack of proper Norwegian reduction works, but of late the Sulitjelma company has not been able to mine with any profit by this plan owing to the cost of transportation. The new process will therefore mean a great deal to the copper industry of Norway.—*Daily Consular and Trade Reports.*

## Gold in Seward-Sunrise Region

Gold was first discovered in Alaska in 1848, in the gravels of streams tributary to Kenai river, by P. P. Doroshin, who was then making an examination of the mineral resources of the district for the Russian-American Co. Owing to the low gold content of the auriferous gravels found at that time, there was little prospecting. Scarcely anything is known of any activity in the goldfields of Alaska between 1850 and 1894, though it is stated that gold was discovered on Cooper creek in 1884, on Resurrection creek in 1888, and at Anchor point in 1889. Placers were found on Bear and Palmer creeks in 1894 and on Canyon, Mills, and Lynx creeks in 1895. These discoveries were followed, in 1896, by a stampede of several thousand men to this field. Crow creek was staked at this time, but did not yield any gold until two years later. In 1898 a second rush, partly an overflow from the Klondike stampede, was made to the Turnagain Arm section.

In a report entitled 'Gold Deposits of the Seward-Sunrise Region, Kenai Peninsula,' by B. L. Johnson, recently issued by the U. S. Geological Survey as Bulletin 520-E, the distribution and occurrence of gold-bearing lodes and placers of the upper part of Kenai peninsula are discussed. Although the present known distribution of auriferous gravels in the district is widespread, the list of producing creeks is small. About 25 claims were being worked at one time or another in 1911, and from 75 to 100 men were engaged in placer mining during the open season. The production of placer gold in 1911 from Kenai peninsula is estimated at 1540 oz. crude, valued at \$26,000 for gold and \$150 for silver. The value of the placer gold of this region varies from \$15.86 to \$17.87 per ounce. Assays of the gold lodes of the region range from \$1 to \$718 per ton.

Although the temperature frequently falls as low as 40° below zero in midwinter, the conditions near Seward, Sunrise, and Hope are favorable for gardening, vegetables being raised in considerable quantities for local consumption. Cranberries, currants, blueberries, huckleberries, and a few salmonberries grow wild. Native grasses are abundant, furnishing good feed for horses during the summer. Considerable hay is now being made in the peninsula, especially in the vicinity of Hope and Sunrise.

# The Black Oak Mill

By CHARLES H. URQUHART

The Black Oak mill at Soulsbyville, on the East belt of the Mother Lode in Tuolumne county, California, marks a new departure in Mother Lode milling practice. It is, I believe, the first all-sliming plant in the state. As it has proved successful, a description may prove interesting.

The mine has been operated intermittently for many years and has an enviable record for gross production. The former method of milling was the customary crushing with light stamps, amalgamating, and concentrating with vanners and a canvas plant. The mill had 40 stamps. The extraction was never good, and many thousands of dollars' worth of high-grade tailing went down the creek. The present company quickly realized that more modern methods of recovering the gold must be employed if the mine was to be a financial success. From results obtained by cyaniding the concentrate, followed by careful tests with the ore, it was found that no unusual or insurmountable difficulties stood in the way of successful treating the ore by cyanidation. The present mill is the result. Nothing remains of the old mill but the building within which all the new equipment is placed, the feeders and the ore-bin.

The ore is fairly high grade, is very hard and silicious, and requires much work to reduce it to pass a fine screen. Even when passing 200 mesh, it is still granular and not a slime in the accepted meaning of the term. It is roughly hand-sorted at the hoist, being dumped from the skip over a grizzly into a small bin holding but a few cars. The coarse material passes through chutes to the sorting platform and the sorted ore is crushed in a Blake crusher, after which it is trammed to the mill. Each car is weighed on platform scales and sampled before reaching the mill. The mill-bin is small, holding but 180 tons. This is not altogether a drawback, as it takes only a little time and labor to level off the ore and accurately measure the contents at any time. As a check on the daily tonnage crushed this has been found to be very valuable. The twenty stamps used in the old mill were light, 750 and 850 lb., and have now been replaced by new stamps weighing 1250 lb. The feeders are the Challenge, of the non-suspended type. The mortars are the high, rapid-discharge, sort, with bases 12 in. thick, and weigh 8500 lb. each. The foundation for the mortars is a monolithic concrete block carefully constructed of selected quartz and granite. Screenings accumulated while coarse-crushing the quartz were mixed with clean river sand, thus making a sharp product for use in the concrete mixture. After shoveling of the concrete into the forms began, it never halted until the entire block was finished. After six months continuous use no signs of deterioration have been discovered.

The ore is crushed in 1.85% cyanide solution, or 3.7 lb. per ton, through Tyler ton-cap screens with openings equivalent to 10 mesh. The pulp passes to a Dorr standard duplex classifier from which the coarse material goes direct to the 5 by 18-ft. tube-mill, being diluted to 39% moisture. The slime-overflow passes to the treatment-tanks. The discharge from the tube-mill is returned to the classifier

by a bucket elevator, so that the pulp must return to the tube-mill until fine enough to escape at the slime end of the classifier; the usual closed-circuit arrangement. A Morse No. 25A 6-in. silent chain and spring sprocket drive takes the place of the customary belts and countershafting. It makes a very neat and compact arrangement, the centres of the motor and tube-mill pinion shafts being but 42 in. apart. Absolutely no trouble from this drive has been encountered during the seven months that the mill has been operating, and it is evident that a considerable saving in power has been made over the belting and counter shaft method of driving.

Considerable trouble was had with the lower bearings of the bucket elevator. Sand and slime worked into the

BLACK OAK MILL, SOULSBYVILLE, CALIFORNIA.

bearings and rapidly destroyed them. This was overcome by placing the bearings 7 in. from the elevator, outside the boot, and putting collars on the shaft between these outboard bearings and the boot to act as baffles. The bearings now keep quite clean and show no wear.

The liners of the tube-mill are smooth cast iron, a mixture of chrome, manganese, and white iron; and are made in a local foundry. They are very hard and, judging from the present rate of wear, should last about twelve months. They are 13½ in. wide, 41 in. long, and 2 in. thick, set staggered with shorter pieces at the ends. Lugs or pads back of the bolt-holes, 4 in. square and ¼ in. thick, prevent breaking the liners when bolting. No cement is used, as the narrow space behind the liners soon fills with slime. After the mill had been running a few weeks, it became apparent that the tube-mill was not keeping up to its early performance. The pebbles were wearing flat and the inference was that they were skidding in the mill, thus losing the tumbling action requisite for effective grinding of this hard ore. Cast strips of hard iron were procured, 3 in. wide, 2 in. thick, and of the same length as the liners. These were bolted in the tube in such a manner that they made long strips 2 in. high the entire length of the tube; a strip for every alternate row of liners. Bolts passing through the strips and main liners take the place of the original bolts; a washer of old belting between the strips and the liner preventing the hard brittle strips from breaking when tightening the bolts. The results were marked, and the output was increased at once. Again the tube-mill was opened and

another set of strips put in, now making a strip for every row of liners. The grinding at once fell off and the starting-load of the motor became excessive. The second set of strips was taken out and the efficiency of the mill returned to the point first reached by the original arrangement of strips. Since these strips have been employed the output of the mill has been increased 13.4%, and the life of the main liners has been materially lengthened. After four months' steady work the strips show but a slight rounding of the upper edges. The mill revolves 23 r.p.m., taking practically 60 hp. to operate and 100% overload to start.

The pulp from the classifier goes to a 20 by 10-ft. Dorr thickener, where it is thickened from a 6 to 1 consistence to 2 to 1 for agitation. When the mill was started the pulp from the thickener was elevated to the agitators by a centrifugal pump, but in a very short time the

compressor furnishes air at 40 lb. pressure for the agitators, the air-lift, and the vacuum-filter. The power consumed for agitation as shown by the meter is 3.4 hp. per agitator.

Having passed through the agitators the pulp flows to another Dorr thickener, the same size as the first. The overflow from No. 2 thickener goes to a small collecting-tank, as it is called, from which it is pumped to the clarification and precipitation presses. The thickened underflow passes to the filter. As the ore milled averages \$20 per ton, the resulting solutions are high in value. In order to reduce the value of the solution in the pulp going to the filter, the contents of the No. 2 thickener are diluted as follows: The overflow from the No. 1 thickener, assaying about \$3 per ton, is passed to the centre of the No. 2 thickener, mixing with the inflowing pulp coming from the agitators, containing solution which

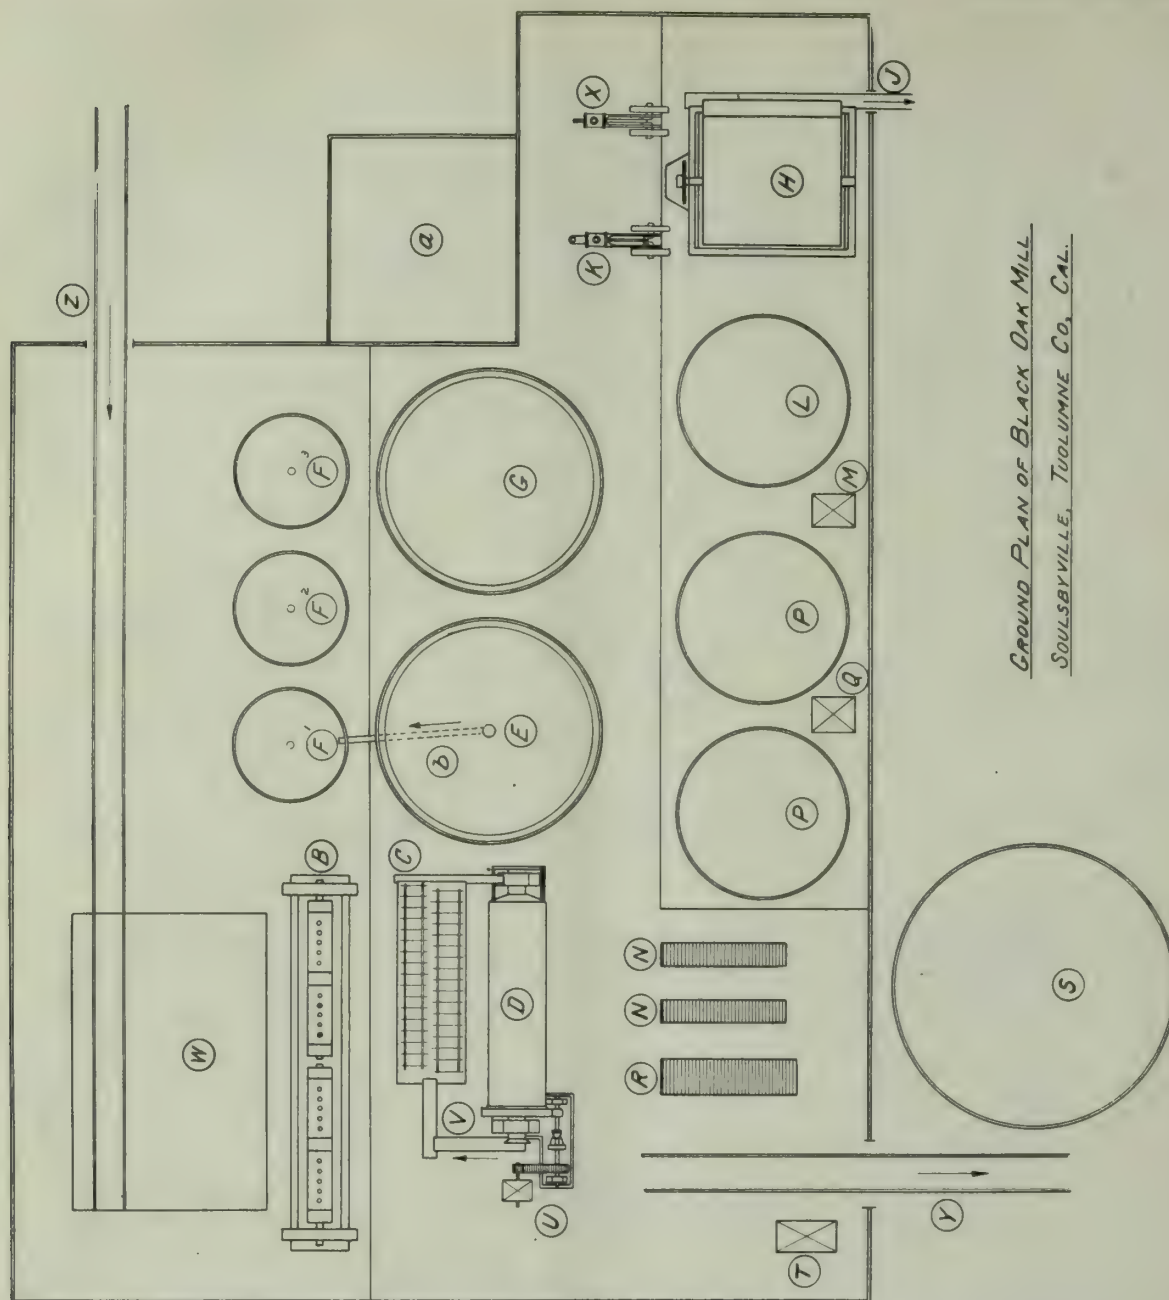

hard gritty slime abraded the liners, flanges, and impeller to a ruinous degree. A 2½-in. air-lift was then substituted, and although the work to be done was not in accordance with good air-lift practice, the total lift being 18 ft. and the submergence but 50%, nevertheless the results have been quite satisfactory and no repairs nor alterations have been necessary. The power consumed is 6 horse-power.

The agitators are three in number and of the Pachuca type, 10 by 30 ft., and connected for continuous agitation. They are so arranged that any agitator can be by-passed and cut out of the circuit, as illustrated in the sketch. In order to make certain that the pulp of uniform grade passes continuously through each agitator, a very simple sampling box is arranged on the end of the pipes connecting them. On the top of the box is a slide which is readily adjusted so as to regulate the amount of pulp flowing in and out of each agitator. This takes an accurate sample of the pulp as it falls from the central tube; a very essential matter when treating a pulp which segregates as rapidly as does the granular product treated here. A spider with six radiating jets supplements the main working air jet as a help in starting at any time. The spider and the main jets are connected with both high-pressure air and high-pressure water, although the water has never been required. An Ingersoll-Rand 8 by 10-in.

assays around \$8. As there is twice as much solution coming from the No. 1-thickener as from the agitators, the resulting mixture of solutions in No. 2 has thus been diluted to about \$3.30 per ton in value. To further dilute this solution, barren solution from the stock tanks is run into the second thickener inflow and also to the thickened underflow. Thus the solution that came from the agitators worth \$8 per ton has been reduced by dilution to under \$2. The filter is an Oliver with a drum 11 feet 6 inches in diameter and 12-ft. face. It is rated by the makers as a 75-ton machine, but with our ore it can easily take care of 100 tons per day. Considering the many excellent filters on the market, the problem of selecting the best one for a new mill is not an easy one. At the Black Oak the Oliver was chosen because in theory the washing of a thin cake seemed more practicable than the washing of a thick cake; because the filter was continuous, simple, and cheap to install and operate; and finally, because a special filterman was not required. Now that the mill crew has become familiar with the machine, it has been found that these conclusions have been borne out in practice and the filter has proved to be splendidly efficient. In the beginning poor results were obtained with the washing. The cake was ½ to ⅝ in. thick and the displacement was incomplete, as much as 20c. being lost at times in dissolved gold and cyanide with the tailing. A spraying

device was later supplied by the Oliver people, and the difficulty was solved at once. The pulp-level in the tank is kept fairly low and an air wash given until the cake emerging from the pulp in the tank has traveled half the distance, when the line of sprays is met and the washing begins. Since the sprays have been installed the displacement has been almost perfect; the solutions are easily kept in accurate balance, and no excess has been built up by over-washing. The filter takes but a small proportion of

the solution-man's time, and the power consumption is small. Repairs are infrequent and cost but little.

Soon after the plant was started a curious black deposit began to form on the filter cloth. It spread rapidly, clogging the cloth, and reducing the available filtering area almost one-half. Hard scrubbing with a 6% HCl solution twice a week eventually removed the deposit. Later the scrubblings were made but once a week, and the HCl solution reduced to 4%. The cloth has been on for seven

months and, barring accidents, should last many months to come. The weekly scrubbing is doubtless the secret of the long life. The filter is scrubbed once a week whether the cloth appears to need it or not. The Oliver filter requires a vacuum pump of much higher efficiency and greater capacity than a leaf type of filter of similar capacity, not only because it is essential to maintain a higher vacuum than is used on the leaf filter, but because

The barren solution passes from the precipitation press to the sump, from which it is returned to the stock tanks above the mill by a triplex 5½ by 8-in. Platt Iron Works pump. It is there brought back to normal strength. Lime is added at the batteries and in the agitators. As the quality of the lime varies, the alkalinity of the solutions is determined in terms of percentage of free alkali rather than in pounds per ton. The amount added by the solution-

WET-VACUUM PUMP CYLINDER FOR T-O TYPE.

a larger quantity of air has to be handled, due to the exposed portion of the drum. For these reasons the types of vacuum pumps commonly in use for leaf-filter plants give very poor results with the Oliver filter.

The pump installed at the Black Oak mill was built by the Doak Gas Engine Co., being a modified type of a pump especially designed by George D. Kislingbury, superintendent of Minas del Tajo, Rosario, Mexico, for the three Oliver filters there. It has a 12 by 10-in. cylinder, and differs from other wet-vacuum pumps in that there are no inlet valves, there is practically no clearance, and the discharge valves are in the piston.

The solution is admitted to the cylinder through ports in its centre, which are opened and closed by the passage of the piston. The solution is discharged through a hollow tail-rod into an enclosed false-head which serves the double purpose of allowing the solution to be discharged under pressure and acting as an air chamber to relieve the shock of the pump. Because of the unusually large valve area the pump may be operated at a speed of 125 r.p.m. without shock, and the small clearance space admits of discharging under relatively high heads without loss of efficiency. A peculiar feature of this pump which puzzles most operators is that it requires only half as much power to operate at 25-in. vacuum as at 12-in. vacuum. The actual power consumed while operating the filter at 22-in. vacuum is 6 horse-power.

The solution from the filter discharges into the collecting-tank mentioned above and is pumped to either of two 24-in. 36-frame Shriver filter-presses for clarification. From the gold-tanks that receive the clarified solution it is pumped to a 52-in. 16-frame Merrill press, zinc dust being added in the customary manner to the suction of the pump. While no difficulty has been found in precipitating the gold almost completely, by allowing the effluent to assay 10 to 15c. per ton, the tendency to accumulate excess zinc is avoided.

man therefore varies slightly from day to day, the working percentage being 0.15% CaO.

Until quite lately lead acetate, 30 to 40 lb. per day, was added with the cyanide in the stock tanks and in the agi-

OLIVER FILTER, BLACK OAK MILL.

tators, but it was found that 24 lb. of commercial litharge would do the same work. As this was considerably cheaper the use of lead acetate was dropped and the litharge substituted. It is added in the tube-mill and in the agitators; an equal amount in each.

A car with a perforated false iron bottom receives the precipitate when cleaning the precipitate press. When the press is empty the car is taken to the refinery, a separate building 75 ft. from the mill. Compressed air which has been heated by passing it through a coil in a small furnace is introduced beneath the false-bottom of the car; as it proceeds up through the mass it rapidly dries the pre-

cupitate. It is weighed on platform scales, fluxed, and smelted in a No. 2 Rockwell double-chamber furnace, no previous acid treatment being necessary. The resulting bars of bullion are base, averaging 850 fine, and a change of the refining method is under consideration. This will possibly include the use of an English cupelling furnace.

High-pressure air from the mine compressor is piped to the mill, acting as an auxiliary in case of emergency. If for any reason the agitators stop and the pulp settles so that difficulty is found in resuming agitation, the high-pressure air is turned on. It is also piped throughout the mill, so that the various motors can be blown free from dust at regular intervals. It is connected to the filter-presses and to the refinery for the crude-oil burners. The main floor of the mill is cemented and provided with drains that all lead to the sump, so that all leaks or overflows are caught.

The mill is equipped with Mazda 'Street Series' tungsten lamps and is brilliantly lighted at night. For mill illumination these lamps are very satisfactory. They have extra heavy filaments, take but little current, cost but a nominal sum to replace, and when suspended with light springs have a long life. They have proved so satisfactory in the mill that the company has installed them over the surface workings and at the hoist and ore-sorting platform. The mill is operated entirely by electric power, which is purchased from the San Francisco & Sierra Power Co. Coming in at 15,000 volts, it is transformed to 440 for power purposes, and further stepped down to 110 volts for lighting.

Since the mill started, the average monthly extraction has never fallen below 95%, and for the last three months has been over 97%. This is the total extraction of gold and silver, and is the actual money shown by bullion returns, not the 'indicated.' The returns on bullion check very closely with the indicated or calculated extraction of the daily mill estimates, usually slightly exceeding them. The cyanide consumption averages 1.5 lb. per ton of ore; the lime 3 lb. One battery-man and a solution-man per shift run the mill with ease. A mechanic attends to the repairs on the day shift, and the mine assayer and a boy do the smelting. The daily capacity of the mill, using light stamps, was 66 tons, but with the new 1250-lb. stamps the output should be at least 100 tons per day with no increase in labor.

## Report of the International Committee on Atomic Weights

\*Since the annual report for 1912 was prepared, a number of important memoirs on atomic weights have appeared. There are also one or two earlier researches which were received too late to be noticed at the proper time. These investigations may be summarized as follows:

**Nitrogen.**—Wourzel, by oxidizing NO to N<sub>2</sub>O<sub>4</sub>, has re-determined the ratio between nitrogen and oxygen. Five concordant measurements give, in mean, N = 14.0068.

**Potassium and Chlorine.**—Staehler and Meyer have made careful analyses of potassium chlorate, with especial precautions against contamination by the chloride. Their final series gives KCl = 74.5551, whence K = 39.097 and Cl = 35.458. For a discussion of their results, see also Guye, who concludes that the impurity above mentioned was, if not completely, at least sufficiently eliminated to be practically negligible.

**Fluorine.**—McAdam and Smith have published two preliminary determinations of the atomic weight of fluorine. Sodium fluoride was converted into chloride by heating in dry, gaseous hydrochloric acid, and from the ratios between the weights the atomic weight was calculated. The two values found are F = 19.0176 and 19.0133.

**Phosphorus.**—From analyses of phosphorus tribromide Baxter, Moore, and Boylston find, in mean of three series, P = 31.027 when Ag = 107.88. This agrees fairly well with the former work of Baxter and Jones on silver phos-

phate. Further work on phosphorus trichloride is promised.

**Mercury.**—Easley and Brann, by analyses of mercuric bromide, find Hg = 200.64. This confirms the previous work of Easley on the chloride.

**Selenium.**—Kuzma and Krehlik have redetermined the atomic weight of selenium by reduction of SeO<sub>2</sub> with SO<sub>2</sub>. The mean of ten determinations is Se = 79.26.

**Tellurium.**—Harcourt and Baker have thrown doubt upon the work of Flint, who claimed to have split up the supposed element into two fractions of different atomic weight. They repeated his method of fractionation, and from the fourth fraction found Te = 127.54. This agrees with the figure found by Baker and Bennett in 1907. Similar fractionations have been carried out also by Pellini, who likewise failed to find any indication of a tellurium of low atomic weight.

**Radium.**—Hönigschmid, by careful analyses of relatively large quantities of radium chloride, finds Ra = 225.95. On the other hand, Gray and Ramsay, using very small quantities of material, and converting the bromide into the chloride, find Ra = 226.36, in agreement with previous work by Madame Curie and Thorpe. Until the discordance between Hönigschmid's low value and the higher is explained, it is undesirable to change the figure given in the table.

**Tantalum.**—The determinations of this atomic weight by Chapin and Smith were made by the hydrolysis of TaBr<sub>5</sub>. The mean of eight determinations gave Ta = 181.80, a figure somewhat higher than that found by Balke from similar analyses of the pentachloride.

**Iridium.**—Hoyermann, by five reductions of (NH<sub>4</sub>)<sub>2</sub>IrCl<sub>6</sub> in hydrogen, finds Ir = 192.613.

**Holmium.**—Six determinations of the atomic weight of holmium by Holmberg gave Ho = 163.45. The well known sulphate method was employed.

There are also approximate determinations of the atomic weights of lead, zinc, and copper by Pecheux, and of calcium by Oechsner de Coninck. The figures obtained are not conclusive enough to justify their use in the table, for the methods employed were not of great accuracy. Only one change is recommended in the table for 1913; namely, the insertion of holmium, for which, hitherto, no good atomic weight determination has been available. Two or three other alterations of small importance might be made, but it seems undesirable to make changes too frequently.

Symbol	Atomic weight	Symbol	Atomic weight
Aluminium	Al 27.1	Molybdenum	Mo 96.0
Antimony	Sb 120.2	Neodymium	Nd 144.3
Argon	A 39.88	Neon	Ne 20.2

# Constitution and By-Laws, American Institute of Mining Engineers

Constitution as proposed November 12, 1912, to be acted upon at the Annual Meeting, February 18, 1913, and prepared by a committee consisting of J. W. Richards, Charles Kirchhoff, and C. F. Rand, under a resolution adopted by the Institute at New York October 7.

## ARTICLE I. NAME AND OBJECT

Sec. 1. This Institute is incorporated under the membership corporation law of the State of New York; its corporate name is AMERICAN INSTITUTE OF MINING ENGINEERS; and its objects are such as are stated in its Certificate of Incorporation.

## ARTICLE II. MEMBERS

Sec. 1. The membership of the Institute shall comprise four classes, namely: 1. Members; 2. Honorary Members; 3. Associates; 4. Junior Members. All members shall be equally entitled to the privileges of membership, excepting that Honorary Members, Junior Members, and Members and Associates whose residences shall be outside of the United States, Mexico, and Canada shall not be entitled to vote. Members and Associates residing within the United States of America, Mexico, and Canada, and not in arrears for dues, shall be entitled to vote in person at the meetings of the Institute, or as hereinafter provided for, by letter ballot.

Sec. 2. The following classes of persons shall be eligible for membership in the Institute, namely: as Members, all professional mining engineers, geologists, metallurgists, or chemists, and all persons actively engaged in mining and metallurgical engineering, geology or chemistry; as Associates, all persons desirous of being connected with the Institute who in the opinion of the Board of Directors are suitable. As Junior Members, (a) all students in good standing in engineering schools who have not taken their degrees and who are nominated by at least two of their instructors; (b) also persons under thirty years of age engaged in learning mining, metallurgy, or geology under the supervision of a member of the Institute. A Junior Member (a) may remain such not longer than three years after leaving the engineering school, or for not more than five years if in class (b), at the end of which period his qualifications to become a Member or Associate must be passed upon by the Membership Committee. If elected he shall pay at that time the entrance fee and dues of a Member or Associate. Every candidate for election as a Member, Associate or Junior Member must be proposed for election by at least three Members or Associates; must be approved by the Committee on Membership, or as prescribed in the By-Laws, and must be elected by the Board of Directors.

Sec. 3. Not less than three-fourths of the votes cast shall be necessary to an election; newly elected candidates shall be immediately notified of their election and also of their obligations, by the Secretary of the Institute. Every person so elected shall become a Member or Associate or Junior Member of the Institute in the class to which he is chosen, upon payment of his initiation fee, if required by this Constitution, and first year's dues, as hereinafter stated. Each candidate for Honorary Membership must be recommended by at least ten Members and must be elected by ballot at a meeting of the Board of Directors by the unanimous vote of the Directors present; provided, however, that the number of Honorary Members shall at no time exceed twenty.

Sec. 4. If any person elected a Member, Associate or Junior Member does not within four months after the mailing of notice of his election accept the same and pay his initiation fee, if required, and dues for the year in which he was elected, his election shall be null and void; and he shall be notified thereof by the Secretary of the Institute; providing, however, that if elected in the months of October, November or December the candidate may, at his op-

tion, pay dues only for the ensuing year, in which case he shall be entitled to receive the *Bulletin* of the Institute for the months of November and December, but not the annual volume of the year during which he was elected to membership.

Sec. 5. The Board may at any time, for good and sufficient reasons, change the classification of a member of any class except Honorary Members.

## ARTICLE III. DUES

Sec. 1. The dues of Members and Associates shall be, until otherwise determined by the Institute, \$10 per annum, and those of Junior Members shall be \$5 per annum. All dues shall be payable in advance on the first day of each calendar year, and notice to this effect shall be published in the last number of the *Bulletin* of each calendar year, and a bill shall be mailed to each Member, Associate and Junior Member on the first day of the month of January in each year, stating the amount of dues and date when payable, and the penalty and conditions incident to default in payment within the limit of time set by the Constitution. Each newly elected Member or Associate shall pay, immediately on notification of his election, an initiation fee of \$10; Junior Members shall not pay any initiation fee. Honorary Members shall not be liable for initiation fees or dues. Any Member, Associate or Junior Member in arrears for one year may, at the discretion of the Board of Directors, be deprived of the receipt of publications or stricken from the list of Members; provided, that he may be restored to membership by the Board on payment of all arrears or may be again proposed and elected after an interval of three years.

Sec. 2. The Board of Directors shall have the right to increase the dues of the membership for the next ensuing year or years by any sum not to exceed the amount of \$5 per annum, such increase of dues to be applicable solely to the extinction of the principal of the land debt of the Institute. As soon as such indebtedness is paid the dues shall automatically return to those provided in Section 1 of this Article.

Sec. 3. Any Member or Associate not in arrears may become, by the payment of \$150 at one time, a Life Member or Life Associate and shall not be liable thereafter to pay annual dues. The money thus received shall be invested and only the income thereof used for current expenses of the Institute.

## ARTICLE IV. BUSINESS MEETINGS OF THE INSTITUTE

Sec. 1. The annual meeting of the Institute for the election of Directors and transaction of other business shall be held at the headquarters of the Institute in the City of New York on the third Tuesday in February in each year. A report of the financial condition of the Institute and an abstract of the accounts shall be furnished by the Directors and presented at each annual meeting.

Sec. 2. Special business meetings of the Institute may be held at such times and places as the Board of Directors may appoint, upon notice to all members and Associates entitled to vote, directed to each at his last known postoffice address, and mailed not less than twenty days before the date fixed for such meeting.

Sec. 3. At all business meetings of the Institute the presence of twenty-five Members and (or) Associates shall constitute a quorum.

Sec. 4. At all business meetings of the Institute, Members and Associates entitled to vote may vote only in person; proxy voting shall not be permitted. Any matter which is presented over the signatures of 25 Members or Associates, or which is advocated or opposed by 25 Members or Associates present at a business meeting of the Institute, or which the Board of Directors may wish to refer to the membership for decision, shall be sent out to the mem-

bership for a vote thereon by letter ballot, accompanied by a statement prepared by the Board of Directors giving the arguments for and against its adoption. Only Members and Associates entitled to vote may vote thereon.

Sec. 5. All meetings of the Institute other than business meetings shall be held at such times and places as the Board may appoint. Notice of all such meetings shall be given to all Members, Associates and Junior Members by mail.

#### ARTICLE V. DIRECTORS AND OFFICERS

Sec. 1. The business, financial, professional, technical, scientific, and social interests of the Institute shall be managed by and under a Board of Directors, elected annually by letter ballot as set forth in the Certificate of Incorporation and in the manner specified in this Constitution or in the By-Laws, to serve for the terms set forth in the Certificate of Incorporation.

Sec. 2. The Board of Directors shall consist of a President, two Past Presidents, six Vice-Presidents, and fifteen Directors. (The six Vice-Presidents of the Council, in office after the annual election, in February 1913, shall be the six Vice-Presidents of the Board of Directors.) Eight Directors shall be elected annually by letter ballot: One of said eight shall be designated as 'Director and President' and two shall be designated as 'Director and Vice-President.'

Sec. 3. The officers of the corporation, who shall also be termed the respective officers of the Institute, shall be a President, First Vice-President, Secretary and Treasurer. The President shall be that Director who is chosen at the annual election as 'President,' he shall serve as President for one year, and for the subsequent two years of his directorate be termed 'Past President of the Institute,' but the President for the year ending in February, 1914, shall be that person chosen to be President of the Council by the members at the annual meeting in February 1913. The President shall be ineligible for reelection as such until two years after expiration of his term as President. At the first meeting of the Board of Directors after the annual business meeting of the Institute, the Board shall elect, from among the Vice-Presidents on the Board, a First Vice-President to hold office for one year; a Secretary, who may or may not be a member of the Board, to serve for one year, and a Treasurer from among the members of the Board to hold office for one year. The Secretary or the Treasurer may be removed from office at any time by a unanimous vote of the Directors present at a special or regular meeting of the Board, due notice having been given in advance that such action is to be considered at said meeting. The duties of all officers shall be such as usually pertain to their respective offices, together with such other duties as may from time to time be prescribed for them by the By-Laws or Board of Directors. The Treasurer shall give a bond for the faithful performance of his duties, in a sum to be fixed by the Board of Directors, but at the expense of the Institute.

Sec. 4. In the event of a vacancy occurring in the Board of Directors by death, resignation, promotion by election as President or Vice-President, or for any other reason than retirement at the end of three years' service, the remaining members of the Board shall elect a successor to fill the vacancy and to serve for the unexpired term. A member of the Board whose term has not expired and who is elected President or Vice-President at an annual election shall be considered to have vacated the former office held by him, and the Board shall fill the vacancy as above provided.

Sec. 5. The Board of Directors may, from time to time, in its discretion, appoint any Past Secretary of the Institute 'Secretary Emeritus,' to receive such compensation and to perform such duties as the Board may designate.

Sec. 6. The Board of Directors may authorize the formation of Local Sections, Topical Divisions, or arrange affiliations with other Societies in accordance with this constitution and the By-Laws.

Sec. 7. The Board of Directors may appoint standing and special committees charged with such duties as the Board may assign. Such committees shall be directly re-

sponsible to, and report to the Board, and take only such responsibilities as the Board shall authorize.

Sec. 8. At the first meeting of the Board of Directors after the annual meeting of the Institute, it shall appoint an Executive Committee of five of its members, three of whom shall constitute a quorum. This committee may act for the Board between meetings of the Board and at any regular or special meeting whenever a quorum of six Directors are not present. The Executive Committee is not authorized to perform the following acts, or any others the Board may see fit to interdict, viz: fill vacancies on the Board; elect the First Vice-President, Secretary or Treasurer; fix salaries of officers (it may fix those of employees); vote extra compensation to officers; vote extraordinary expenses or incur obligations of over five hundred dollars; take action affecting already invested funds or property rights of the Institute; elect Honorary Members; expel Members.

Sec. 9. The Chairmen of Local Sections or appointed representatives thereof, and the chairmen of the Technical Committees or Divisions of the Institute, if not members of the Board of Directors, shall be notified of and have the privilege of attending all meetings of the Board, but without the right to vote. They may participate in discussion, and shall receive the minutes of the Board's meetings.

Sec. 10. All salaries paid by the Institute shall be fixed in advance by the Board of Directors, but no salary shall be fixed in advance for a period longer than twelve months.

Sec. 11. The funds of the Institute shall be paid out only by check signed by the Treasurer and countersigned by the Secretary; in case of absence or disability, the President or First Vice-President may act for the Treasurer, or any Vice-President for the Secretary.

Sec. 12. The Directors may appoint an Assistant Secretary who shall, under the instructions of the Board, have charge of such of the business affairs of the Institute as may be assigned to him by the Board. His salary shall be fixed by the Board, and he shall hold office during its pleasure.

#### ARTICLE VI. MEETINGS OF THE BOARD OF DIRECTORS

Sec. 1. A regular meeting of the Board of Directors for the election of officers and the transaction of other business shall be held in February in each year, at the headquarters of the Institute, in New York City, after the annual business meeting of the Institute has adjourned.

Sec. 2. The Board of Directors shall also meet once each month except in July and August, on a regular date to be fixed at its February meeting, for the transaction of such business as may come before it. A conference of the Board may be called at the request of three members of the Board, or by the President, to meet at any time or place, in connection with a meeting of the Institute for reading and discussion of papers or for the discussion of matters affecting the welfare of the Institute. All recommendations adopted by a majority of those present at such conference shall be transmitted to the Secretary of the Institute, accompanied by a record of the number favoring such recommendations, together with notes of the discussion thereon, and by him brought before the next meeting of the Board of Directors, for consideration and such action as it may deem expedient. Special meetings of the Board shall be called by the Secretary at the request of the President, First Vice-President, or any three members of the Board, to meet at any time and place, by notice mailed to the members of the Board at least ten days in advance, or by telegram sent at least five days in advance of the date of the meeting to members in North America (Alaska excepted).

Sec. 3. At all meetings of the Board of Directors the presence of six members shall constitute a quorum. In the absence of said quorum, at any meeting of the Board, a quorum of the Executive Committee, if present, shall transact such necessary business as is within the powers delegated to that Committee.

# ARTICLE VII. NOMINATION AND ELECTION OF DIRECTORS AND OFFICERS

Sec. 1. A ticket of nomination for offices and places annually falling vacant in the Board of Directors shall be prepared by a Committee on Nominations, of which no member shall be, at the time, on the Board. This Committee shall consist of the Chairmen of three Local Sections, one Past President, and three other members of the Institute, and on recommendations made by the President of the Institute, shall be appointed by a vote of the Board of Directors, within ninety days after the annual meeting, and it shall then proceed to the selection of candidates and the naming of a ticket. In making such selections, the nominating committee shall, so far as practicable, distribute the representation on the Board geographically, so that seven members shall be residents of the district including New York City and the territory within a radius of fifty miles of the headquarters of the Institute, and one member a resident of each of the geographical districts enumerated in the By-Laws.

The official ticket thus formulated shall be transmitted to the Secretary of the Institute, not later than the last Friday in October, be submitted to the Board at its October meeting for its consideration, published in the November *Bulletin*, and, not later than January 1 be printed and sent to the membership. Any complete or partial ticket of nominees signed by any 25 Members, or Associates of the Institute and transmitted to the Secretary by December 15 shall also be printed and circulated with the official partial ticket of nominees signed by any 25 Members or ticket and over the names and with the recommendations of the nominators, together with an expression of opinion of the Board thereon if deemed expedient.

Sec. 2. The election ballots mailed with the nominations shall contain space for the naming of eight Directors, of which the first shall be designated: 'For Director and President', the second and third: 'For Director and Vice President', and the rest: 'For Director'. They shall be accompanied by small inside adhesive envelopes marked: 'Ballot. Do not sign,' and outer mailing envelopes addressed to the Secretary and marked 'Enclosing Ballots only.' Members voting shall not sign their names to the ballot, but seal it in the inner envelope, enclose it in the outer mailing envelope, and write their names on the outside, in the place provided. Cumulative voting shall not be permitted. Letter ballots must reach the Secretary on or before the second Tuesday in February. He shall give them unopened to tellers, to be appointed by the Board of Directors at its January meeting, at least three days before the annual business meeting, marking plainly those from Members not entitled to vote, because of geographical location or by being one year or more in arrears for dues. The tellers shall open and count the valid ballots received from Members entitled to vote, rejecting any unidentified by the name of the sender on the outer envelope; they shall prepare a report of the voting and hand it to the Chairman of the annual business meeting of the Institute. The latter shall declare elected to the respective offices the eligible persons receiving the highest number of votes. The ballots and unopened letters shall be returned to the Secretary at the annual business meeting; the latter shall preserve them one month, and then destroy the ballots which have been counted, and open and destroy the others.

# ARTICLE VIII. PAPERS AND PUBLICATIONS

Sec. 1. The Board of Directors shall appoint a Committee on Papers and Publications, of which the Secretary shall be a member, whose duty shall be to pass upon the fitness of technical communications submitted for publication by the Institute. Stenographic or contributed discussions of papers may be passed upon by the Secretary, in consultation with members of the above Committee.

Sec. 2. The Institute shall not assume responsibilities for any statements of fact or opinion advanced in the papers or discussions at its meetings. Neither the Board nor the Institute shall officially approve or disapprove any technical or scientific opinion or of any proposed enter-

prise, which is outside of the management of the meetings, discussions and publications of the Institute, and the conduct of its business affairs by the Board of Directors.

Sec. 3. Special committees may from time to time be appointed by the Board to make investigations and prepare reports for presentation to the Institute, but no action shall be taken binding the Institute for or against the conclusions embodied in any such reports.

# ARTICLE IX. SUSPENSIONS AND EXPULSIONS

Sec. 1. Any Member of the Institute who shall be convicted of a crime involving, in the opinion of the Board of Directors, moral turpitude, shall, upon passage by the Board of Directors of a resolution declaring the crime for which he has been convicted to be of such character, be thereupon dropped from membership in this Institute.

Sec. 2. Any Member of the Institute may be suspended or expelled for misconduct by the Board of Directors, after charges setting forth such misconduct shall have been prepared and filed in writing with the Board. Upon the receipt of such charges in writing the Board may, in its discretion, suspend such Member pending a hearing and determination thereupon. As soon as may be after the receipt of such charges, the Board shall fix a date for a hearing thereupon and shall give to the accused Member notice thereof in writing, mailed to him at his last known post-office address not less than thirty days before said date, accompanied by a copy of the charges and a copy of the second, third and fourth sections of this article.

Sec. 3. Upon the day fixed for the hearing, the accused Member may appear before the Board, either in person or by an accredited representative; hear any witnesses who may be called in support of the charges and, at its option, cross-examine the same, and hear read any documentary evidence offered in support of the charges. The accused may, in his discretion, produce and examine witnesses in his defense, and submit documentary evidence, including a statement from himself in writing. After the conclusion of the hearing, the Board of Directors shall consider and vote to approve or disapprove the charges. If the Board shall, by a vote of two-thirds of its members, declare the charges sustained, it may suspend the Member for a stated period, or expel him.

Sec. 4. If the accused Member shall not appear at the hearing, and shall within three months thereafter file with the Board an affidavit stating that he had not received notice of the charges against him in time to enable him to present his defense, the Board shall fix a date for a re-hearing within three months from the receipt of such affidavit, and shall immediately notify the accused Member by mail of such date. Upon the re-hearing, shall have the same privilege of presenting his defense as he would have had upon the original hearing; and after the defense is presented, the Board shall take a new vote upon the charges, the result of which shall be conclusive.

# ARTICLE X. AMENDMENTS

Sec. 1. Proposals to amend this Constitution shall be presented in writing to the Board of Directors, signed by at least ten Members; they shall reach the Secretary not later than October 15. The Board of Directors shall consider them and the proposers shall be notified of the opinion of the Board in regard to them, and they may then either withdraw their proposals, or accept any changes suggested, or insist on the original form. The original form, if insisted upon, together with the changes proposed by the Board, if such there be, shall be mailed to all Members on or before January first, with the election ballots, and with a ballot in proper form for voting upon the amendment in its original or amended form. Ballots shall be received by the Secretary until the second Tuesday in February. The Tellers of the election shall count these ballots, and report the result to the Chairman of the annual meeting. Any Members present in person at the annual meeting who have not voted on the amendments by ballot, shall have the privilege of having their votes recorded before the result of the voting is announced.

## PROPOSED BY-LAWS

## I. PRESIDING OFFICER

At all business meetings of the Institute the President, or in his absence, the First Vice President, or in the absence of both of them, any other Vice President or Director, chosen by the meeting shall preside. At all other meetings of the Institute the President or, in his absence, one of the Vice Presidents shall preside. If none of these be present the meeting shall elect a Chairman.

## II. ORDER OF BUSINESS

At each business meeting of the Institute the order of business shall be as follows: (1) Reading of minutes of preceding meeting; (2) report of the President; (3) report of the Treasurer; (4) report of the Secretary; (5) report of Tellers of Election; (6) reports of standing committees; (7) reports of special committees; (8) special orders; (9) miscellaneous business. This order of business may be changed at any meeting, by a vote of a majority of the Members and Associates present. At all sessions of the Institute, other than business meetings, the order of proceedings and the time of adjournment shall rest in the discretion of the presiding officer.

## III. SECRETARY OF THE INSTITUTE

The Secretary shall keep a record of the proceedings of all meetings of the Institute. He shall be custodian of the corporate seal, of the minute books and of all legal documents belonging to the Institute. He shall have charge, on behalf of the Institute, of all correspondence except such as pertains directly to the office of the Treasurer. He shall notify all Officers and Directors and all members of committees of their election and appointment; shall issue notices of all meetings of the Board, and of the annual and other business meetings of the Institute; and shall, in calling special meetings of the Directors, specify the objects of such meetings. He shall act as clerk at all the meetings of the Board of Directors and at all meetings of the Institute. The Secretary shall be custodian of all technical or scientific papers submitted to the Institute for its consideration, shall have general charge and supervision of the editing and proof-reading of all material published by the Institute, and of the distribution thereof, and be ex-officio Chairman of the Committee on Publications. On the first day of May following the year in which each volume of *Transactions* is printed, he shall turn over to the Library Committee all copies of the same not theretofore distributed by him. The Secretary may, with the approval of the Board of Directors, employ such persons as are necessary to constitute a clerical and office force, at such salaries as shall be approved by the Board of Directors or its Executive Committee. He shall be the immediate superior of all such employees.

## IV. ASSISTANT SECRETARY

The Board of Directors may, upon request of the Secretary, appoint an Assistant Secretary, to take charge of such portion of the Secretary's duties as may be assigned him by the Board or its Executive Committee, such as supervising the printing and distribution of advance papers, of the *Bulletin* and *Transactions*, soliciting advertising and conducting general business correspondence. He may be appointed also Assistant Treasurer, if the Board shall so determine, to collect annual dues and accounts due the Institute, subject to instructions from the Treasurer of the Institute. During the absence of the Secretary at meetings of the Institute, or for other reasons, he shall act as Secretary *pro tem*.

## V. TREASURER

The Treasurer shall collect and, under the direction of the Board of Directors, shall disburse all funds of the Institute. He shall keep regular accounts in books belonging to the Institute, which shall be open to any member of the Board of Directors. He shall report in writing at each annual meeting of the Institute, and at every regular meeting of the Board of Directors, the balance of money on hand, and any existing appropriations which may affect the same. His accounts shall be audited annually by a committee of three Members or Associates to be appointed by the President at

least thirty days prior to the annual meeting in each year, which committee shall report thereon at such annual meeting. The committee may employ a public accountant to assist it, at the expense of the Institute. The Treasurer may, at his discretion, place funds of the Institute, not at any time exceeding five hundred dollars, in the hands of the Secretary, Assistant Secretary, or Assistant Treasurer, and may delegate to either of them the duty of paying, therefrom, the smaller current expenses of the Institute. The Treasurer shall examine this 'Cash Box' account each month. The Treasurer shall be solely responsible to the Institute for all moneys received, whether the same are entrusted to others or not, and may require from any one to whom he entrusts funds, a bond, running to the Treasurer personally and taken at the expense of the Institute.

## VI. ASSISTANT TREASURER

The Board of Directors may appoint an Assistant Treasurer, to whom it may delegate the duties of conducting, under the supervision of the Treasurer, correspondence incidental to the office of Treasurer, of collecting, receiving, and depositing in bank, to the credit of the Institute, all moneys, and of paying, out of special account, if entrusted to him, the smaller current expenses of the Institute, subject to the instructions of the Treasurer.

## VII. STANDING COMMITTEES

The standing committees of the Institute shall be four: A Finance Committee, a Library Committee, a Committee on Publications, and Committee on Membership. The Finance Committee shall consist of three members of the Board of Directors, who shall be appointed by the Board at its first meeting after the annual meeting of the Institute in each year. The Library Committee shall consist of the Secretary of the Institute and four other Members or Associates of the Institute, one being appointed annually by the President, at the first meeting of the Board after the annual business meeting of the Institute, to serve for four years, in conformity with the By-Laws of the United Engineering Society, approved by the Board of Directors of the Institute. The Committee on Publications shall consist of the Secretary of the Institute, who shall be its chairman, and at least twelve specialists, Members of the Institute, to assist in passing on all papers offered for publication. They shall be appointed annually by the newly-elected President. The Committee on Membership shall consist of five Members of the Institute, the Chairman, and at least one other member being chosen from the Board of Directors, and shall be appointed by the President at the first meeting of the Board after the annual business meeting of the Institute.

## VIII. FINANCE COMMITTEE

It shall be the duty of the Finance Committee to inquire into and examine the financial condition of the Institute and to consider proper means of increasing its revenues and of limiting its expenses. It shall report at each monthly meeting of the Board, and at other times whenever it shall desire or be directed so to do; and the Treasurer shall at all times furnish it with such statements and information as it may desire. It shall determine, with the approval of the Board, the investment of such surplus moneys as shall from time to time accrue to the Institute. It shall, at least once in each year, examine the securities belonging to the Institute, and report thereon to the Board. It may, at any time, examine the books and vouchers of the Treasurer and Assistant Treasurer. The Treasurer shall not be a member of the Finance Committee, but shall attend the meetings of the same if requested. The Finance Committee shall present a budget to the Directors at the meeting preceding the annual meeting of the Institute. This budget shall give an itemized estimate of the receipts and expenses of the Institute for the ensuing year. The Directors shall pass on this budget at their first meeting after the annual business meeting of the Institute, modifying it as they consider necessary, and make definite, detailed appropriations for the following year. All bills, accounts, salaries, pay-rolls, and claims of every kind against the Institute shall, before being paid, be examined by the Finance Committee and be ap-

proved by at least one member of the Committee. The Committee shall not authorize any payments in excess of appropriations. If at any time any of the appropriations seems in danger of being insufficient the Finance Committee shall report the same to the Directors.

#### IX. LIBRARY COMMITTEE

The Library Committee shall constitute the official representatives of the Institute upon the Library Board of the United Engineering Society, and be guided by the By-Laws of that Society, as approved by the Board of Directors of this Institute, with full powers to act for the Institute within the appropriations allowed by the Board of Directors. The Library Committee shall be the custodian of all books in the Institute library and of additions thereto; also of all back numbers of the *Transactions* of the Institute. It shall, on the first day of May of each year, receive from the Secretary and receipt for all the volumes of *Transactions* and *Bulletins* or other publications for the preceding year not previously distributed by said Secretary. It shall cause to be kept, under the directions of the Secretary, a catalogue of all books in the library and an account in ledger form of all volumes of *Transactions* in its custody, in which shall be charged all volumes delivered to it, and in which shall be credited all volumes taken from its custody for sale or for any other purposes. It shall make a written report annually to the Board of Directors, stating the stock of publications on hand, and a detailed statement of sales during the year, together with such observations and recommendations as it may wish, regarding said publications or the conduct of the library.

#### X. COMMITTEE ON PUBLICATIONS

1. This Committee shall perform its functions as follows:

(a) On the receipt of a paper by the Secretary (Chairman), he shall send it to the member of this Committee who, in his judgment, is most competent and available to pass upon it, as 'Reader,' accompanying the paper with his own opinion of its suitability for publication, and any other pertinent information.

(b) If the Reader and the Chairman agree upon the suitability or unsuitability of the paper; it shall be considered accepted for publication or rejected, as the case may be.

(c) If these two do not agree, the paper shall be submitted to a third member of the committee, and the opinion of two of these three members shall decide the matter.

(d) If a paper has been refused publication, the author shall have the right of appeal, in which case the persons previously passing on the paper, together with others selected from the Committee by the President—making five altogether—shall decide the question.

(e) If a paper has been accepted for publication, it shall be considered eligible to be placed on the program of a meeting.

2. The placing of a paper upon the program of a meeting shall not give it the right to be published in the *Bulletin* or *Transactions* of the Institute; its suitability for publication must in every case be passed upon by the Committee, as provided for in Section 1, of this Article.

3. In case the Secretary is unable to secure a decision as to the suitability or unsuitability of a paper for publication, as directed in Section 1, before the time of announcing the program of a meeting, he may at his own discretion place the paper upon the program of the meeting, or refuse it a place thereon.

#### XI. COMMITTEE ON MEMBERSHIP

All nominations for Members, Associates, or Junior Members of the Institute shall be submitted to and passed upon by the Committee on Membership. This Committee shall meet at least once in each calendar month, with the exception of the months of July and August. It shall receive and consider all communications respecting candidates and shall make diligent inquiry as to the character and qualification of each. Its proceedings shall be reported to the Board, if required, but otherwise shall be secret and confidential. No member of the committee shall propose any candidate.

#### XII. ELECTION OF MEMBERS

After the Committee on Membership shall have reported to the Board its conclusions as to the acceptability of each candidate, the Board shall vote upon the same. No person shall be proposed for election to the Institute within one year after his name shall have been rejected by the Board.

#### XIII. NOMINATIONS

The geographical districts to be considered by the Committee on Nominations shall be as follows, until otherwise ordered by the Board.

*District No. 1.* New England, New York, and New Jersey, excepting New York City and district, which is provided for in the Constitution.

*District No. 2.* Pennsylvania.

*District No. 3.* Ohio, Indiana, Illinois, Iowa, and Missouri.

*District No. 4.* Minnesota, Wisconsin, and Michigan.

*District No. 5.* Montana, North and South Dakota, Wyoming, Nebraska, Kansas, Washington, Oregon, Idaho, and Alaska.

*District No. 6.* California and Nevada.

*District No. 7.* Utah, Colorado, Arizona, and New Mexico.

*District No. 8.* Louisiana and Texas.

*District No. 9.* Other Southern States and District of Columbia.

*District No. 10.* Mexico.

*District No. 11.* Canada.

#### XIV. UNITED ENGINEERING SOCIETY

This Institute shall be represented upon the Board of Trustees of the United Engineering Society by three Members or Associates, one retiring each year, as provided in the by-laws of the said United Engineering Society. At the December meeting of the Board of Directors the Board shall designate a Member or Associate of this Institute to be a representative of this Institute upon the Board of Trustees of the said United Engineering Society for a period of three years beginning at the next ensuing annual meeting of said Society. At any time when a vacancy shall occur in the representation of this Institute on the Board of Trustees of said Society, the Board of Directors of this Institute shall designate a Member or Associate to fill such unexpired term. These representatives shall report in writing to the Board of Directors at its regular meetings held in March, June, September, and December, and at other meetings, if called upon by the Board.

#### XV. PUBLICATION OF A BULLETIN

The publications of the Institute shall include, in addition to the *Transactions*, a periodical called the *Bulletin* of the American Institute of Mining Engineers, which shall contain reports of proceedings, professional papers, notices, and other matters of interest to Members. From the annual dues paid by each Member, Associate, and Junior Member, five dollars shall be deducted and applied as a subscription to the *Bulletin* for the year covered by such payment. Special volumes upon technical subjects may be issued, by vote of the Board.

#### XVI. OBLIGATIONS TO MEMBERS

Any Member of whatever class whose dues are paid within the limits set by the Constitution shall receive the *Bulletin*; and all Members and Associates who pay \$10 annual dues, also all Life and Honorary Members, shall receive in addition the *Transactions*.

#### XVII. LOCAL SECTIONS

Sec. 1. A Local Section of the Institute may be authorized by the Council at the written request of ten Members residing within an appropriate distance of a central point.

Sec. 2. The Board shall define the territory of a Section.

Sec. 3. Only one Section shall be authorized in one locality or district.

Sec. 4. A Section must consist of at least twenty-five members; if its membership falls below twenty-five in number, the Board may annul the Section.

Sec. 5. Only Members of the Institute shall be members of its Local Sections.

Sec. 6. All Members and Associates of the Institute, residing within the territory of a Section shall be eligible for membership in such Section. But any such person failing within three months, after due invitation, to become a member of such Local Section shall thereafter be admitted to its membership and privileges only on such conditions as said Local Section shall determine.

Sec. 7. The officers of a Section shall be elected, after the formation of the Section has been duly authorized, at a meeting of the Members of the Institute within the territory of said Section, called by the sponsors of the Section, notice of said meeting and its objects being given to said Members at least thirty days in advance. Officers of Local Sections shall be elected for a term not longer than one year.

Sec. 8. The Officers of a Local Section shall be a Chairman, Vice Chairman, Secretary, Treasurer (or Secretary-Treasurer), and such others as the Section may desire.

Sec. 9. It shall be the policy of the Board of Directors of the Institute to contribute from its funds for the necessary running expenses of each Local Section, when and so far as practicable, an amount not exceeding, in each year, 25% of the dues received from the members of said Section in said year, but in no case exceeding the sum of \$250. Requests for such appropriation shall be signed by the Chairman, Secretary, and Treasurer of the Section.

Sec. 10. If the expenses of a Section exceed the appropriation made by the Board, the difference may be made up by voluntary contributions from the members of said Section, if it shall so determine. The Institute shall not be responsible for the debts of any Section.

Sec. 11. The Board reserves the right to cancel a Section, or re-adjust its territory.

Sec. 12. Papers presented at Local Sections, and discussions thereon if reported, shall be the property of the Institute. They shall be submitted to the Publication Committee and published in the *Bulletin* or *Transactions* or both, if approved. Such papers shall not be published elsewhere *in extenso* without permission of the Board. The reading of a paper before a Local Section shall not carry with it the right of publication in the *Bulletin* or *Transactions* of the Institute.

Sec. 13. Neither the author of a paper presented to a Local Section nor the Local Section shall have the right to reprint a paper or publish it in advance of the meeting without obtaining the permission of the Publication Committee of the Institute, which may refuse, or determine the details of such permission. Nothing herein shall forbid the abstracting of a paper by the press after its presentation before a Local Section.

Sec. 14. The Institute shall print advance copies of papers offered to Local Sections, in order to facilitate discussion thereon, provided that such papers are approved for such advance publication by the Chairman or Secretary of the Local Section and by the Publication Committee of the Institute.

Sec. 15. Papers read before a Local Section may also be offered for reading or discussion at general meetings of the Institute, and shall be given equal standing with the other papers on the program of said meeting, when approved by the Publication Committee.

Sec. 16. Each Local Section shall transmit promptly to the Secretary of the Institute announcements of its proposed meetings and an abstract of its proceedings, including the names of authors and titles of all papers read before it, for the purpose of preparing a report thereon to be published in the *Bulletin* of the Institute and for the purpose of enabling the Board of Directors to comply with sections 17 and 19 of these regulations.

Sec. 17. The By-Laws and regulations of Local Sections shall be subject to the approval of the Board of Directors.

Sec. 18. No action shall be taken by a Section which shall contravene the Constitution and By-Laws of this Institute.

Sec. 19. The Board reserves the right to amend, annul, or add to this Article XVIII of the By-Laws.

#### XIX. TECHNICAL COMMITTEES

Sec. 1. A Committee on Iron and Steel, in charge of the interests of the Institute in this branch of its activities, is hereby established.

Sec. 2. Other technical committees may be authorized by the Board of Directors, charged with the consideration of such topic or topics as the Board may assign, and having the duty of providing papers and discussions upon such topics for the meetings of the Institute.

Sec. 3. The Board of Directors shall designate the officers thereof, who shall hold office for one year or until their successors are appointed.

Sec. 4. The officers of a Technical Committee shall be a Chairman, Vice Chairman, and a Secretary.

Sec. 5. The Committee may adopt such rules as are necessary for the convenient conduct of its affairs, subject to the approval of the Board of Directors, or its Executive Committee.

#### XX. AFFILIATION OR CONSOLIDATION WITH OTHER SOCIETIES

The Board of Directors may arrange conditions for the affiliation or consolidation with the Institute of any regularly organized group of engineers or any engineering society, whether heretofore or hereafter incorporated or otherwise, which by Constitution, By-Laws, and practice is in accord with the aims of this Institute.

#### XXI. AFFILIATED STUDENT SOCIETIES

Sec. 1. Any society of undergraduates at a technical school, comprising students in any branch of engineering, metallurgy, chemistry, geology, etc., may be recognized by the Board, in its discretion, as an Affiliated Student Society, and its name, together with the names of its president and its secretary, may be published in the *Bulletin* or the Year Book of the Institute. The individual members of such a society will not be catalogued as individual Members of the Institute, but may at any time be proposed for election as Junior Members of the Institute, in the usual way, and receive the *Bulletin* of the Institute, when elected, upon payment of \$5 annual dues.

Sec. 2. Technical papers presented before any such society, and recommended by the officers thereof, will be received and considered by the Publication Committee as if offered by Members of the Institute, and, if accepted will be published, with the names of their authors, and with due acknowledgment to the said Affiliated Student Society. The members of such societies shall be welcome to use the facilities of the office and library of the Institute.

Sec. 3. Upon the request of the Secretary or other designated officer of any such society, accompanied with the necessary remittance, not more than three copies of the *Bulletin* for one year shall be sent postpaid to him at reduced price given to public libraries. One volume of *Transactions* may be similarly furnished at the price charged Members of the Institute for extra copies.

Sec. 4. The conditions and details of this relation between the Institute and Affiliated Student Societies may be changed at any time at the discretion of the Board of Directors of the Institute; and the relation itself may be terminated at any time by the action of either party.

#### XXII. AMENDMENTS

Sec. 1. Amendments to these By-Laws may be made by vote of a majority of the Directors, provided the amendments have been proposed by a member of the Board at a previous meeting of the Board and copies of the same sent to all members of the Board at least 20 days before the meeting at which they are to be voted on, and an expression of opinion invited thereon. At a later meeting they may be amended in form, but not in substance.

Sec. 2. Any Member or Associate of the Institute in good standing, may propose amendments or additions to

these By-Laws, by sending such in writing to the Secretary. The proposal shall be brought before the Board at its next meeting, and, if sponsored by any one member of the Board, shall pass through the course required in the previous section. If the proposal is not so sponsored, it shall be returned to the proposer.

Sec. 3. Amendments or additions to these By-Laws may be proposed by sending the same in writing to the Board of Directors so that they are received by them at least 60 days before a business meeting of the Institute, and providing they be endorsed by the signatures of at least 20 Members or Associates in good standing at the time. It shall be the duty of the Board of Directors to have such proposals printed in the next succeeding issue of the *Bulletin*, and to provide proper facilities for a vote of the membership thereon by letter ballot before the said business meeting. If favored by a majority of the ballots cast, the amendments shall be reported at the said business meeting as adopted, and shall thereupon become effective.

#### PROPOSED CLASS OF FELLOWS

The committee has been requested by a large number of members of the Institute to propose as a part of the new Constitution an article creating a class to be called 'Fellows,' and in response to that request the article appearing below has been prepared. At the meeting of the Institute in Cleveland, Ohio, October 30, this article was much discussed and at the request of the committee a vote was taken. Of those present who chose to express an opinion, 21 were in favor of it and 27 were against it. In order to give Members an opportunity to pass upon this question without affecting their votes on the new Constitution as a whole, the matter is now proposed separately. We hereby propose an amendment to the Constitution of the American Institute of Mining Engineers to read as follows:

#### ARTICLE XI

##### FELLOWS OF THE INSTITUTE

Sec. 1. The distinction of 'Fellow of the Institute' may be conferred upon a Member of the Institute who has been for at least ten years prominent in his profession, in responsible charge of mining, metallurgical, geological, or chemical work, or of educational work concerned therewith.

Sec. 2. The Board of Directors shall have the right to designate twenty-five members of the Institute as Fellows, and they shall be the nucleus of this body.

Sec. 3. Hereafter a candidate for the distinction of Fellow of the Institute must be nominated by at least five Fellows, and the nomination be sent by the secretary of the Fellows to the Secretary of the Institute, and after notice of said nomination has been published in the *Bulletin* three successive months, be elected by mail ballot of the Fellows. He shall be declared elected if 75% of the ballots cast are favorable to his election. Such elections to fellowship shall take place once yearly, at the time of the annual meeting of the Institute.

Sec. 4. The Fellows of the Institute shall hold at least one annual business meeting in each year, preferably on the date of the annual meeting of the Institute, at which those Fellows present shall elect a chairman, vice chairman, and secretary, to serve for one year, and adopt such rules and regulations for the activities of their body as may seem to them desirable and are in agreement with this Constitution and the By-Laws.

Sec. 5. Any Fellow who is guilty of unprofessional conduct may be deprived of his standing as Fellow of the Institute by a three-fourths vote of the Fellows, taken by mail after presentation of the matter in full by a committee of the Fellows.

Sec. 6. Fellowship in the Institute terminates with lapse of membership in the Institute.

Respectfully submitted,

JOSEPH W. RICHARDS,  
CHARLES KIRCHHOFF,  
CHARLES F. RAND.

## Modified Bunsen Valve

By LESLIE RUSSELL MILFORD

In making analyses of total iron, I have adopted the following scheme in working on the Saratoga mineral waters. When reducing the ferric compounds to ferrous, by means of nascent hydrogen, an Erlenmeyer flask with a Bunsen valve attachment has been used. The accompanying cut shows at a glance the modification which has been satisfactory.

A, Erlenmeyer flask; B, cork; C, bulb cut from 10-c.c. pipette; D, rubber tubing; E, glass plug; SS', slits for valve.

Instead of an ordinary straight piece of glass tubing a bulb, C, from a discarded 10-c.c. pipette is used, one end of which is inserted into the cork B, projecting just below the surface into the Erlenmeyer flask A; to the other end is joined a piece of rubber tubing, D, carrying a glass plug, E. The ferric solution to be reduced is put into the Erlenmeyer flask, dilute sulphuric acid and zinc dust are added, and the flask is then placed on the steam bath. The nascent hydrogen produced by the action of the acid on the zinc reduces the iron rapidly. When all of the zinc is in solution the flask is taken from the bath, placed on a wire gauze, and the contents are brought to boiling so as to eliminate any hydrogen in the flask, as this would decompose the  $\text{KMnO}_4$  solution when added. It is at this point that the improved valve works to advantage. The steam in escaping expands in the 10-c.c. bulb, condenses and runs back into the flask. This eliminates the excess pressure and possible blowing out of the stopper. After thorough boiling, the flask is taken from the gauze, the stopper removed, the sides washed down, and a very little c.p.  $\text{NaHCO}_3$  is dropped into the flask to generate an atmosphere of  $\text{CO}_2$ . The solution is then titrated with standard  $\text{KMnO}_4$ .—*Jour. Ind. and Eng. Chem.*

## Hydraulicking on the Panama Canal

Hydraulic excavation in the Pacific division will be completed about December 1, 1912, according to the *Canal Record*, when the plant will be dismantled. For some time past, operations have been in the canal channel, south of Miraflores locks, and have about reached the point where the cost of excavating by this method would probably exceed the cost by steam-shovels. A good bottom has been obtained for shovel work on the east side of the channel below the dam, and from there the shovels will be in position to make favorable progress.

Excavation by the hydraulic method was begun in September 1910, and the equipment was first used in filling the core of the west dam at Miraflores, the monitors at that time working in the lower lock site at Miraflores. The hydraulic fill of the dam was completed on December 4, 1911, and amounted to 625,048 cu. yd. Prior to this time, the zone of operations had been moved farther south into the channel section, and, when the fill of the dam was completed, the material disintegrated by the monitors and pumped out by the dredge pumps was carried to the nearby tidal swamps. A total of about 110 acres of swamp land had been reclaimed to November 1, 1912. The total excavation accomplished by the hydraulic plant from the beginning of operations to November 1, 1912, aggregates 1,723,800 cu. yd. During the fiscal year ended June 30, 1912, the total cost of handling the material, earth and rock, by the hydraulic method, was \$0.5564 per cubic yard.

NATURAL GAS amounting to 207,112,576,000 cu. ft., valued at \$28,451,907 was produced in West Virginia in 1911 from about 4755 wells.

## Decrease of Value in Ore-Shoots With Depth—II

By F. LYNWOOD GARRISON

J. F. Kemp, of Columbia University, in his discussion of my paper on the 'Decrease of Value in Ore-Shoots with Depth,' at the Toronto meeting of the Canadian Mining Institute,<sup>1</sup> seemed to think my general conclusions on the subject did not sufficiently take into account the phenomena of secondary enrichment as a factor bearing on the apparent decrease of value with depth. Before discussing this aspect of the subject, if indeed it be a phase of the case, it is desirable to clearly understand what is meant by secondary enrichment. It is well known that in many ore deposits there evidently have been several successive periods of metallic deposition and the mineralizing waters or vapors may have come from lower, higher, or lateral sources. My understanding of the usual expression, 'secondary enrichment,' is solely that increase of metallic value which is derived from the leaching by surface waters of the upper part of an orebody above ground-water level; the leaching and accompanying oxidation of this portion of the lode taking place usually, but not necessarily, simultaneously. Of course, the ground-water level may have changed through the geologic history of the deposit, and the lode, enriched as we now find it below the present ground-water level, may have acquired this accretion when this water was much lower than now; or, conversely, the secondary enrichment of today may be far above the present ground-water level. Now evidently secondary enrichment strictly interpreted, may come from above, below, laterally, or from any and all directions. The difficulty in most cases is to determine what was primary ore. When we construe the term 'secondary enrichment' to mean only that which is derived from above, it is much less difficult to at least guess what was the primary mineral substance upon which the meteoric waters deposited their metallic burden. Accepting this as the common view, and applying it exclusively to the enrichment due to downward circulation, it is evident that secondary enrichment is substantially a superficial phenomena, depending upon the depth of the ground-water level or plane, which in most instances has been, and perhaps still is, a varying factor. As the ground-water level falls, the leaching action penetrates deeper. It may rise again and the depleted area be once more enriched by the mineralizing waters from higher horizons, the difficulty is to know where it begins, ends, or how far it has penetrated.

That brings us to another phase of this problem of ore deposition. It has long been assumed that chalcocite is a secondary mineral, in other words, a creature of secondary enrichment in the usually accepted sense. It is true it is usually found at no great depth, generally occurring intermediately between the oxidized portion of the copper lode and the deeper lying pyritic portions, which latter is usually assumed to be primary ore. Expressed in simple terms, the chalcocite is derived from the leached and oxidized part of the lode, its deposition and accumulation occurring at or about ground-water level. Our faith in this generally accepted view has been lately somewhat shaken by recent developments at Butte, Montana, where chalcocite has been found at depths of 2000 ft. vertical. According to Charles T. Kirk, it is a fact that the secondary concentration of chalcocite has not been reached at a depth of nearly 3000 ft.<sup>2</sup> The chalcocite at the Bonanza mine,<sup>3</sup> in the Chitina River district, Alaska, is probably the largest body of chalcocite ore yet discovered. It occurs in the Nikoli greenstone or diabase, as irregular lenticular and vein-like bodies replacing the rock or disseminated through it in small particles. In places the chalcocite is associated with epidote. Much larger masses of particularly pure chalcocite occur in the adjoining Chitistone limestone, by replacement of the

original rock. F. H. Moffit leans toward the belief that in both the limestone and greenstone the chalcocite is of secondary origin, being probably derived from leaner sulphides.<sup>4</sup>

It seems likely as a general principle that similar metallic minerals in the same limited area, and even in the same rock, may have had a diverse genesis. Thus the minerals epidote and allanite, long assumed to be of characteristic secondary origin, are shown by a number of investigators to have been in many cases primary, and a constituent of unaltered igneous rock. Allanite and epidote are representatives of a large number of metalliferous and non-metalliferous substances which enter into the constitution of igneous rocks. They indicate how widely metal-bearing components may occur, and how differently they may be found without being of extraneous origin. They occur as primary minerals under conditions far more extraordinary and seemingly impossible than those under which many metallic salts are found.

As affecting the general principle that richness in ore-shoots does decrease with depth below, say, 1000 or 1500 ft., some interesting observations have come to my notice since writing the paper under discussion.

At the Mysore mine, in the Kolar district, India, the latest reports show a decided impoverishment at the bottom levels, 2500 to 3000 ft., the value of the ore decreasing from \$50 per ton in the upper reaches of the mine to \$20 per ton at the 3000-ft. level.<sup>5</sup> At the annual meeting of the Mysore Gold Mining Co., held in London, March 20, 1912, the chairman stated:

"With regard to pursuing mining operations in greater depth, we have been questioned by more than one shareholder as to whether we anticipate any grave difficulty in following ore to largely increased depths. I say, in answer to this, that we have no sort of difficulty at the depth at which we are now working, and with the provision of the requisite machinery we see none in going to very greatly increased depths. My questioners appear to be under the impression that we have already reached exceptionally great depths in the Mysore mine, but I would like to remind them that after all the mine has only attained a vertical depth of about 3000 ft., although on its underlay it is over 4500 ft., whereas I could instance to you mines which are today being worked at a vertical depth of over 5000 ft., and a depth on the underlay of over 8000 feet."

At the North Butte mine in Montana it has been asserted on authority which may or not be reliable, that on the 2200-ft. level of the Snowball vein the orebodies average 3 ft. in width, 4% copper, and 10 oz. of silver. This vein was opened about January 1912; since then the same lode has been developed on the 2000 and 2200-ft. levels, the work on each succeeding level in depth showing not only increases in value but longer and more persistent ore-shoots.

In a comprehensive and comparatively recent review of the mining conditions in Western Australia,<sup>6</sup> A. Montgomery states: "It is undeniable that in Western Australia, as in all other parts of the world, the lower levels of the mines have not been so productive as those nearer the surface, but it does not seem to me that in this respect they have shown any more lack of permanency in depth than those of most other mining fields, nor is there any satisfactory reason yet apparent why valuable ore should not be found to persist in them to quite as great depths as in any other mining region, say to 4500 ft., as in Bendigo, or even to the immense depth of 6000 ft. at which mining in South Africa has been seriously contemplated. \* \* \* As a mat-

ter of fact, good ore has been found in Western Australian mines at the greatest depths to which mining has been carried, namely the 2650-ft. level of the Great Boulder mine. So far as work has gone at that level, it is true that value has not been so satisfactory as at the 2500-ft. level, and there has been much fear expressed in consequence that this famous mine was at last failing. But some good ore has been obtained, and it must be remembered that at all the levels it has been often easy to miss the best ground until a great deal of exploration has been done. \* \* \* In almost all the mines of Kalgoorlie it has been found essential to do a great deal of boring across the strike of the vein to find hidden ore, and the first drift along the lode has often been anything but a true test of its value. This local peculiarity must be recognized and allowed for, and time given to open the ground pretty thoroughly before jumping to the conclusions about extinction of values. \* \* \* The whole history of the Boulder mines from below the oxidized zone has shown a succession of pessimistic forecasts of its early decease, and from time to time the prospects of first one and then another of them have appeared very doubtful. \* \* \* Time and again, however, further exploration has brought about new developments, and the position has improved, and there is therefore always much hope that perseverance will be rewarded. \* \* \* Another characteristic feature of the lodes of Western Australia is the unusual amount of secondary enrichment which appears to have gone on in most of them near the surface, especially in the zone of oxidation above the water-level. This has often led to much disappointment when the deeper parts of the lodes have been reached, but it is a feature which is now becoming much better understood than formerly, and for which allowance is to be made. There is, however, much doubt yet as to the depth below surface to which its effects are perceptible. \* \* \* A great deal of the fear that is expressed as to permanency of ore deposits in depth is often founded on what is really an entirely unproved assumption, though it has a certain amount of *prima facie* probability—namely, that in a deposit formed by ascending hot waters the metals would be likely to be in solution in the deeper zones when at higher temperature and under high pressure, and would only be deposited in ascending through the crust of the earth as the temperature and pressure are reduced and the solutions come in contact with more superficial waters carrying precipitants. It is somewhat inconsistent that this view should be put forward as a reason for expecting falling off in value in veins like those of northern New Zealand, which seem plainly to be of hydrothermal origin and outcrop probably at no great depth below the original outlets of the hot springs which formed them, and also for the pneumatogenetic lodes of Kalgoorlie, the portions of which now accessible to us have most probably been formed at great depths under pneumatolytic rather than hydrothermal conditions."

In contradiction to these optimistic views of Mr. Montgomery, we note that recent reports from the Ivanhoe at Kalgoorlie indicate a decrease of value in the ore reserves of the lowest levels of 2s. 10d. (67c.) per ton.<sup>7</sup> A more detailed later report from the Ivanhoe seems to cast doubt upon this conclusion, for it states that the main shaft is over 2600 ft. deep and is being slowly but steadily deepened. A bore-hole put in from the Great Boulder at 2800 ft. pierced a lode, at 57 ft. from the south and 12 ft. from the east boundary, assaying 89s. 6d. (\$21.48) per ton. This proves that good ore persists and that the present workings are in a poor zone. Development in the adjoining Horse-Shoe mine confirms this inference.<sup>8</sup>

The following interesting instance is given by George J. Hough<sup>9</sup> of the occurrence of oxidized ore at comparatively great depths. Near the little town of Ramos in the north-western corner of the state of San Luis Potosi, about 35 miles east of the city of Zacatecas, Mexico, there is the Cocinera mine, which attained about the year 1901 a depth

of 1200 ft. At 1100 ft. a large body of oxidized ore was found, containing its copper almost entirely as red oxide associated with native silver and some small amount of an apparently new variety of stromeyerite, having a composition about  $A_2Cu_2S$  with a massive perfectly homogeneous structure. As to deep-lying oxidation, a similar condition occurs at Bisbee, Arizona, where the level of oxidation is very erratic, extending to at least the 1400-ft. level, while at other places sulphide ores are found within 200 ft. of the surface.

If the metallic minerals of a lode result from the concentration of traces of metals disseminated throughout accompanying and associated rocks, it is to be expected that such mineralization will not extend much beyond or remote from the areas or spots where these attendant rocks have been decomposed and more or less leached; consequently when there is a good and copious flow of water in deep workings there must be as deep or deeper channels for its circulation and where there has been a sufficient fracturing of the accompanying rocks to provide such fissures, it is fair to assume some of them have been filled or choked with depositions of mineral matter perhaps sufficiently rich to constitute ore. During the past summer I had the opportunity of going through the lower levels of the Mexican mine on the Comstock Lode and the deeper workings in the North Star mine at Grass Valley, California. At both of these places there is good ore, not as rich as has been found higher up, but on the whole excellent in value and grade, with promise of continuance, or perhaps it would be better to say, at present no indications of discontinuance with depth. The levels to which I refer are below 2000 ft. and are accompanied by a copious flow of water. The discovery of the orebodies at these deep levels was not the result in either case of wholly fortuitous circumstances, but the reward of intelligent and courageous development. When we consider the intense heat and other discouraging difficulties presented by both nature and man which at present surround and hamper all enterprise and progress on the Comstock, Whitman Symmes deserves a meed of praise no money can ever compensate or anyone fully appreciate who has not been through those deep, hot, and suffocating stopes.

As is well known, the underground flow of water in the Comstock is enormous. It is believed by F. Becker to have its source in the high Sierra some 15 or 20 miles west.<sup>10</sup> His hypothesis that some of the drainage of these mountains reaches a great depth below the Washoe district and is heated by contact with deep seated and still hot eruptives is plausible, and, if accepted, assumes very deep fissuring in the plane of the lode. Admitting such is the case, it is not unreasonable to assume that some portions of these fissures may be filled with mineral substances rich enough to be denominated ore, and at levels considerably deeper than 3000 ft. Our knowledge of the physical and chemical processes going on in deep-seated rocks is certainly shadowy. We do not know how deep fissuring and faulting has progressed; without voids and fine cracks for the circulation of mineral-bearing solutions, veins cannot form even by replacement. It must not be assumed that deep underground circulation implies a large flowage of water. It seems probable much of this movement may be credited to water in closely confined spaces and moving with inconceivable slowness.<sup>11</sup>

The time honored conception of ground-water held that there existed a standing aqueous body universally present at a fairly definite distance below the surface. The upper limits of an orebody were assumed to be sharply defined and indicated by the line or zone of demarcation between the oxidized and enriched ones and the unaltered sulphides. The supply of water was maintained by that part of the rainfall which sinks into the ground.<sup>12</sup> The fact that a great body of standing water is usually found at no great

<sup>12</sup>J. F. Kemp, 'Role of Igneous Rocks in the Formation of Veins,' Trans. Amer. Inst. Min. Eng., Vol. 31, p. 184.

depth below the surface in regions of considerable rainfall makes it necessary, according to this theory, to believe that rocks are pretty thoroughly saturated with water down to depths where the return journey begins, in fact, as C. R. Van Hise expresses it, "there is a sea of ground-water." Van Hise in particular rejects specifically the igneous rocks as significant contributors of either material or energy in the hypothesis he seeks to establish.<sup>13</sup> He contends that the waters which fill the veins with mineral are meteoric and that gravity is their motive power. There are grave objections to this conception when examined in the light of experience gained with deep wells and shafts, for as previously intimated, they show in most cases a decided disposition of the rocks to become progressively drier with depth. A further review of this subject is not contemplated save to observe that the views of Van Hise, although admirably worked out and presented, do not harmonize with the experience of mining engineers who have had occasion to study conditions in very deep mines. It would seem that these conceptions of Van Hise as well as those of C. S. Slichter<sup>14</sup> must be revised if they are to fit in with the practical facts ascertained in recent years, at least so far as concerns conditions existing in crystalline rocks.

Instances close at home are not wanting wherein good ore has been found at increasing depths; thus at the famous old Dolcoath mine in Cornwall a substantial improvement in the tin lode was found at the 490-fathom (2940-ft.) level where the ground yielded 60 lb. of 'black tin' for the full width of the drift.<sup>15</sup> At Guanajuato, Mexico, we have a great lode (Veta Madre) resembling in many respects the Comstock. Mining operations were begun here about the year 1554 and the principal shaft, the Valenciana, had reached a depth of 1800 ft. when operations were finally suspended in 1897, chiefly owing, it is asserted, to inability to handle the large influx of water. The orebody in the Valenciana was worked to a depth of 1640 ft. vertical, then by winzes about 200 ft. deeper. It is asserted the bottom was in bonanza ore; there may have been ore at the bottom, but whether sufficiently rich to yield a profit in the face of the increasing pumping and hoisting costs with the old equipment is doubtful. The impression I have obtained from a careful perusal of the most reliable statements to be had, is that Valenciana is bottomed in ore, but not bonanza ore in the sense of being abnormally rich.

Ponciano Aguilar, of the Mexican Geological Survey, is credited with the statement through H. E. Miller<sup>16</sup> that the lower levels of the Valenciana mine were comparatively dry, that the flow of water which caused the cessation of work in the shaft, came from the higher levels, from the hanging wall crossing through the faults and cross-veins. It has been observed in this case that the richest ore was along the hanging-wall side of the vein, where also there was most water, the inference being that the water naturally followed the lines of maximum fissuring, bearing out the hypothesis that the water circulation and ore deposition are often, if not usually, concomitant phenomena. The exact depth of the Valenciana shaft is another matter of doubt. Probert<sup>17</sup> gives it as 1807 ft.; Halse,<sup>18</sup> 1968 ft.; Ramirez,<sup>19</sup> 2042 ft.; Dahlgren,<sup>20</sup> 2100 ft.; and Tilman,<sup>21</sup> 1968 ft. The Nueva Luz (a new shaft), which is to be cross-cut into the underlay of the Valenciana orebody, is 2030 ft. vertical, the deepest shaft in Mexico. According to Halse, from the 300-ft. to the 1200-ft. levels in the Valenciana rich ore was abundant; below this, impoverishment began to appear.<sup>22</sup> Halse, in the paper mentioned, cites eighteen or twenty instances of Mexican mines having shafts of over 1000 ft. vertical depth. In nine of these

cases there was a distinct impoverishment in the lowest levels, but in most of the other instances given the value of the ore held up pretty well at the bottom. This paper was published seventeen years ago (1895); doubtless many of these shafts have been, in that interval, sunk much deeper; it is to be regretted we have no later data regarding them. Mexico is an excellent illustration of a country containing a large number of relatively deep mines ranging from 1000 to 1800 ft. vertical. Such probably is to be expected in a country where the mining industry is comparatively ancient. It is, however, presumable we have here a terrain which has been subjected to relatively little erosion, hence with few or no stumps of lodes. But such conclusions must be accepted with great caution, or at least until more is known about the geology of the country than is now the case; doubtless at some places in Mexico the degradation has been considerable, yet on the whole the erosion cannot be anything like as great as that suffered by those parts of North America once covered by the great ice sheet of the Glacial period. In the discussion of the Halse paper, H. F. Collins stated he was not prepared to believe "in any continuous or general impoverishment of fissure veins in depth \* \* \* they were just as likely to find one vein rich at the surface, yet poorer in depth, as they were to find another poor at the surface yet rich in depth." Of course, those poor at the surface would not

VIEW OF GUANAJUATO.

be likely to be worked, and therefore it might happen that in the majority of cases veins rich at the surface would appear to become poorer in depth; it was, however, merely because the veins evidently poor at surface did not get worked as much.<sup>23</sup> Mr. Collins further stated it was perfectly true that most veins showed a zone of enrichment near the surface, but he thought it essential to clearly distinguish between the evidences of surface enrichment and of steady or gradual impoverishment with depth. These views were expressed seventeen years ago. It is but fair to suppose the speaker's ideas may have changed somewhat in that long period; moreover, as previously intimated, none of the mines in Mexico at that date exceeded 1000 to 1800 ft. vertical depth.

It has been objected that this discussion as a whole is 'academic,'<sup>24</sup> the inference being it has or eventually would have no practical value; that it is, in other words, learned rather than utilitarian. No better refutation of this view could be asked than the valuable observations from the New-house tunnel made by Mr. Collins, wherein we have a practical illustration of the non-persistence of some veins and the persistence of others at a depth of 1500 ft. as exposed in this working; the latter showing little or no change of general character or extent of mineralization, while the former wholly fail to penetrate to that depth. It is only in the collation of such data as this by competent observers that we can hope to make these dissertations of essential value to the student and public. Doubtless much which creeps in is mere talk, but so far as we have gone in this instance there remains, I believe, not a little of practical value.

## The Ophir Cyanidation Plant

The new plant of the Ophir Silver Mining Co., operating on the Comstock Lode, has now been in operation a little over a month, and was briefly described in the *Virginia City Chronicle*, by Walter Techow, who, after designing and erecting the mill, is now in charge of its operation. In building the plant an excellent record for speed was made. It was ordered by the directors June 22. The first work of grading began on July 15, and while the lumber did not arrive on the ground until the end of the month, the actual construction began early in August. The frame was put up during that month, and the building inclosed early in September. The machinery was also installed in September, the finishing touches made early in October, the plant started October 14, and has been running continuously ever since. The plant is complete with the exception of the clean-up room, now being added, and soon to be placed in commission. With the melting facilities available, the first clean-up will be made.

According to Mr. Techow, the plant was designed for a capacity of 100 tons per day. During the first two weeks after starting, it treated 1065 tons. During the third week 625 tons was handled, and during the past week the plant has been running at a rate of more than 100 tons per day. The process adopted consists of re-grinding the coarse part of the tailing from the old Kinkead mill, agitating the re-ground tailing with cyanide solution, and separation of the gold and silver-bearing cyanide solution from the now barren tailing. The tailing is re-ground in a 5 by 22-ft. tube-mill furnished by the Union Iron Works. One problem in connection with the erection of this mill was how to get the wet and sticky material to the tube-mill, and the method adopted was to sluice it from the pond to the tube-mill. This method has proved successful and economical, as the cost of getting the tailing into the mill is only about 9c. per ton. The tailing is sluiced into the tube-mill with dilute cyanide solution and is continually in contact with cyanide solution from the moment it leaves the pond until the treatment is completed.

From the tube-mill the re-ground tailing passes to a Dorr thickener 28 ft. in diameter by 8 ft. high, where it is settled and the excess of the cyanide solution is removed. This solution is pumped back to the tailing pond and is kept continually in circulation. The settled slime is elevated from the bottom of the Dorr thickener into one of a series of three agitating-tanks, 16 ft. high and 22 ft. in diameter. These agitating-tanks are equipped with Trent agitators. They require little power and do excellent work if properly erected and looked after. After about 24 to 36 hours agitation with an additional amount of cyanide, the slime is transferred to a storage tank and passes from this tank to the Butters filter. The gold and silver-bearing cyanide solution leaves the filter clear, and passes on to the precipitating-boxes, while the tailing is discharged from the Butters filter and allowed to run to waste.

The original estimate of the cost of operation of this plant was \$1.25 per ton. It appears now, however, after one month's operation, that the estimate was too high. The cost of treatment will probably not exceed \$1.20 per ton, and possibly may be lower. The consumption of cyanide is at present less than three-quarters of a pound per ton or an equivalent of \$0.19 per ton. The total cost of labor will come to about \$0.40 per ton. The power consumed during the first two weeks was at the rate of 100 hp. It will probably be less in the future, as all the machinery was new and in the process of being limbered up.

Up to the present time, by the records at the plant, the tailing treated has averaged about \$5 per ton before treatment and \$1 per ton after, thus indicating an extraction of approximately 80%. It is believed, however, that further experiments and improvements will raise the extraction to 85%, or possibly higher. It will be of interest to

again recall that the tailing is the product of the Kinkead mill, which by the process of concentration, extracts 84 to 87% of the original value of the ore as shown by the smelter bullion returns. It can thus be concluded that a final loss of \$1 per ton represents only 2 to 3% of the first head sample at the Kinkead mill. The total extraction at the mill and cyanide plant will, therefore, undoubtedly average 97% or better of the gross value of the ore. This extraction, according to figures furnished at the Ophir office, is being obtained at a total cost of \$3.75 per ton for both milling and cyaniding.

## A Souvenir Medal

We present below a picture of the beautiful medal struck in commemoration of the visit of the American mining engineers to Japan in 1911, and sent by them to their Japanese friends. The medal was designed and manufactured by Tiffany & Co., and is made of gold bronze framed in ebony. Replicas have been sent to each of the members of the general committee and to others prominent in entertaining the visitors. In addition, life memberships in the American Institute of Mining Engineers have been purchased and presented to Reija Kanda, M. Otagawa, and W. Watanabe, to whom the visitors were indebted for many especial cour-

tesies. The selection and presentation of the souvenirs was made by a committee consisting of D. W. Brunton, F. C. Smink, and F. H. Daniels.

Of the industries of the Union of South Africa, mining is by far the most important. The total value of the principal minerals produced in South Africa up to the end of last year was approximately as follows: gold, \$1,579,715,000; diamonds, \$777,600,000; coal, \$113,210,000; copper, \$43,740,000; and tin, \$7,260,000. During December 1911 the mining industry of the Union gave direct employment to 31,700 white and 259,600 colored persons. The amount of gold ore crushed during the past year was 25,000,000 tons, yielding 8,250,000 oz. of gold, valued at \$170,000,000. The profits amounted to \$57,348,000, and the dividends \$38,991,780. The increase in the production over 1910 was \$14,895,900, principally due to new producers. The value of the output of the other principal minerals during the past year was as follows: diamonds, \$38,510,420; coal, \$9,438,120; copper, \$2,702,160; and tin, \$2,016,900.

THE oil industry in the Taranaki division of New Zealand has excited a good deal of comment from time to time. The first attempts to prove the oil-bearing country were from 1865 to 1868, and the second period of activity was from 1889 to the present. There are now four oil companies holding property in or near the area examined, but the combined output is little over 100 bbl. per week.

## Special Correspondence

### LONDON

CAMP BIRD REPORT.—FURTHER INVESTMENTS BY THE COMPANY.—MESSINA DEVELOPMENT.

The annual meetings of the Camp Bird, Ltd., The Santa Gertrudis Co., Ltd., and the Messina Development Co., Ltd., have just been held in London. The Camp Bird company carried forward a surplus of £51,000, against £39,000 brought forward last year. The profit and loss account, as made up from quarterly reports, covering fourteen months, from May 1, 1911, to June 30, 1912, showed £245,000, less £11,000 charged off for taxes, £8000 for depreciation and other sundry expenses, amounting to a total of £22,000, leaving a balance to the profit and loss account of £223,000, Camp Bird's proportion of Santa Gertrudis profits during a like period amounting to \$202,000 net, being 81%—a total of £250,000 to the credit of the Santa Gertrudis profit and loss account. One of the chief items of interest in the Camp Bird balance sheet is an expenditure of £79,225 invested in the purchase of the Aviado-Recupera-dora shares. These shares have since been transferred to the Santa Gertrudis company.

The principal item of interest discussed at the meeting was the outlook for further production from the old Camp Bird mine, and in this regard A. M. Grenfell, chairman of the board, said in part:

"I think we may look forward with every confidence to another prosperous period; but as the Camp Bird becomes exhausted we begin to depend more on dividends from Santa Gertrudis. The developments at Camp Bird seem to justify Mr. Cox's estimate that we may still expect a profit in Camp Bird of £60,000. The orebody being developed is quite promising, but inasmuch as the finding of ore at this horizon is contrary to the expectations of the experts, I do not care to attempt to prophesy, though there does seem a sporting chance of our finding a fair orebody here. There is always a possibility—a small one, perhaps, but still a possibility—that we may be on the top of an entirely new body. Mr. Cox has thought well enough of the prospects to sink the shaft down 200 ft. below the present drifts, and, as I have said, should we find that the values are maintained at this depth, we may begin to speculate on the probability of considerable future profit from the Camp Bird mine." In reference to the Santa Gertrudis, Mr. Grenfell said: "I will say here that if the estimates of the engineers of the Santa Gertrudis are borne out, that mine should give a profit this year of £360,000, taking silver at 55c. per ounce, or if you take silver at the price of today, the profit should come up to £412,000, of which the Camp Bird proportion would be £304,000. Adding this to the £60,000 we should receive as profit from the Camp Bird, we may look forward fairly safely, I think, to an income this year of £364,000, so that we have every reason to congratulate ourselves, not only on the past, but on the immediate future. Furthermore, from the reports of the Santa Gertrudis, it appears that that mine has sufficient ore in sight to yield very large dividends during the next four or five years, so that not only are we in an exceptionally good position today, but I think we may look forward to very satisfactory profits during the next few years; in fact, our position appears to me to be so strong and so satisfactory that the board are of opinion that we should take advantage of our prosperity to establish ourselves on a really sound and lasting basis."

One of the important items of discussion at this meeting was in regard to the policy of the Camp Bird company as to the making of further investments similar to that made in the Santa Gertrudis property. As to this Mr. Grenfell said: "During the next four or five years it should be our policy to build up a reserve fund of £600,000 or £700,000, if we can do so without in any way impairing the real benefits of the shareholders. As it is, today we are dividing our profits up to the hilt. We are making little provision for the maintenance of dividends or

for accidents or shut-downs which might happen to Santa Gertrudis, just as it happened in Camp Bird, the idea being that shareholders in mines arrange for their own sinking fund, but in all properly managed industrial companies the board of the company incurred this responsibility, and I think that all shareholders who really think out the position of the company will come to the conclusion that I have come to, namely, that undoubtedly the soundest policy is for us to make hay while the sun shines, and to so shape our policy now, when everything looks prosperous, to assure our future beyond all possible question. At the present moment we are considering—together with probably one of the strongest groups of mining people in America, and with one of the strongest groups in France—purchasing a very well known mine in Mexico. It is a mine that has been reported on by nearly all the best known engineers; but the owners' idea of its value was too extravagant, and we have acquired an option on it on terms which, with small modifications, may be considered satisfactory. As the negotiations are still going on, and as our preliminary corps of engineers has only just reached the mine, you will not expect me to make any definite statement as to which the mine is or what is the purchase price; but suffice it to say that even the third share which has been reserved for Camp Bird will require a considerable sum of money, and provided that the results of the examination satisfy our engineers, there is no doubt, in my opinion, that it is an opportunity that should not be missed. Had we been in the fortunate position of having a lot of spare cash, I would like to have had a bigger interest for the Camp Bird. As it is, our participation is such that we can see our way to financing it, and the profits which should accrue to the company would be considerable."

With reference to the Messina development, the situation is covered by Mr. Grenfell's statement to the effect that the option which the Camp Bird holds on the 125,000 shares of Messina Development now shows a paper profit of between £30,000 and £40,000. It is very interesting to note the work which the Camp Bird is doing in Mexico, and it is not out of the way to say that there is hardly a precious-metal mining company in America that has as well satisfied a list of shareholders as is possessed by the English companies, including Camp Bird, Esperanza, and El Oro. The full reports made by these companies are a source of satisfaction to the investors, and while there has been some strong criticism leveled at the Camp Bird management as to the manner in which the Santa Gertrudis purchase was made, similar deals made by American companies are hardly noted as a matter for adverse comment.

### BLACK HILLS, SOUTH DAKOTA

HOMESTAKE CHRISTMAS PRESENT.—DEVELOPMENT OF THE REPUBLIC.—WORK AT THE GOLDEN REWARD

Appreciating the loyalty and efficiency of its employees, the Homestake Mining Co. announces that on December 31 it will pay to each employee a sum equivalent to 7% of the pay drawn during the past year. In connection with this announcement, the statement is made that the company is enjoying the most prosperous year in its history. The output of the mines is larger than ever before, and everything is running smoothly. The royalty contracts with C. W. Merrill, under which the cyanide plants of the Homestake were operated, have all expired, the last to be canceled being the contract for the big slime plant. The two cyanide plants and the slime plant will be operated, as in the past few years, under the direction of A. J. Clark, the company's metallurgist, ably assisted by W. J. Sharwood.

The Republic Mining Co., a reorganization of the old Golden Gate Mining & Milling Co., has started work on its property at the head of Blacktail gulch. The Golden Gate company was one of the first in the Black Hills to successfully adopt the cyanide process. After a shut-down of 14 years, the owners decided that a little more work might put their property on a paying basis, and the stockholders, who are wealthy men of Chicago and Oregon, Ill.,

raised funds among themselves to carry on development, with the understanding that if the mine warrants they will furnish money to build a mill. An old shaft has been cleaned out, equipped with a 30-hp. electric hoist and other machinery, and from its 100-ft. level a cross-cut is being driven to the Maggie shaft, to drain the old workings and give ventilation, as well as to develop the intervening territory. The old workings contain considerable quantities of ore, which, although formerly too low grade to work, is now suitable for milling. E. J. Hoover is general manager and C. C. Todhunter superintendent.

The roasting plant of the Golden Reward, at that company's Astoria mine, is rapidly nearing completion, and it will probably be in operation by the first of the new year. The ore from the Astoria shoot is soft and wet, so that it must be dried before going to the rolls; this will be accomplished, after a preliminary crushing to  $\frac{3}{4}$  in., in cylindrical driers. From the rolls the ore will go direct to the Wedge 7-hearth mechanical furnace, fired by crude oil. After passing through coolers, the roasted ore will be elevated to a cylindrical steel bin for loading into cars for delivery to the company's cyanide plant at Deadwood. The roasting plant will have an initial capacity of 75 tons per day, but provision is made throughout the plant for duplication of all machinery, so that the capacity can be doubled when necessary. The Astoria ore-shoot has been explored for a length of 2200 ft., with the limit not yet found. The shoot is 8 to 12 ft. thick, and 100 to 150 ft. wide. After roasting, the ore is easily and cheaply cyanided. The Astoria shaft has been equipped with a new head-frame, a Leyner double-drum 82-hp. electric hoist, and a 100-hp. air-compressor. Among other surface improvements are a complete machine-shop, assay office, sawmill, and ore-bins for reception of ore from other mines of the company. It is the present intention to make tests on roasting the so-called blue ores from other openings. The entire plant has so far cost approximately \$75,000. It was designed by Frank Cazin, of Denver, and Henry Schnitzel, general manager for the Golden Reward company.

At the Wasp No. 2 the old zinc-boxes have been replaced with three new steel boxes, of heavy construction. The compartments are 3 by 4 by 2 ft., each box having five compartments. The change has already effected a material saving in zinc, and it is hoped to reduce the zinc consumption one-half. This is quite an item when zinc, as at present, costs \$10.10 per cwt. delivered at the Wasp spur. The Wasp No. 2 company is enjoying a prosperous year, having already paid \$85,000 in dividends this year, and another \$10,000 disbursement is expected next month. This makes the most prosperous year in the history of the company.

The Trojan company is getting in good shape for winter, having made a number of improvements, including housing the ore-bins and switch tracks, repairing and enlarging the heating plant, and completing other protection against cold weather. A fully equipped machine-shop is rapidly nearing completion. This shop will be one of the most complete in the Black Hills, containing lathes, punches, shears, drill-presses, bolt-machine, and drill-sharpener. The equipment is such that practically all ordinary repairs will be made on the ground. After a year's test of a gasoline locomotive for ore haulage, a second has recently been ordered and delivered. It is practically identical with the first, having a capacity of 11 to 12 cars of one ton each over the 4% maximum grade. In addition to the big producer of the company,

the Decorah, the Portland and Empire are rapidly being gotten into shape for ore production. At the former property an electric hoist is at work, and at the latter a hoist and air-compressor, both electric driven, are being installed. With the new improvements completed, and the mill capacity raised to 400 tons per day, early next year, the Trojan will be the largest producer in the Bald Mountain district.

### SUTTER CREEK, CALIFORNIA

LINCOLN CONSOLIDATED DISCOVERY.—SHAFT-SINKING AT KENNEDY.—NEWS OF NEVADA COUNTY.

The new vein intersected in the Wildman ground by the drift from the 1900-ft. level of the Lincoln Consolidated is reported to range from 6 to 7 ft. wide. Free gold and sulphides are evident. The company is arranging for development. The find was made beneath the point where the big vein was cut in the Wildman mine several years

AMADOR CITY AND THE KEYSTONE MINE. FROM AN OLD PHOTOGRAPH.

ago. The east cross-cut on the 2540-ft. level of the Central Eureka has cut a vein in the virgin ground recently acquired by the company. A winze is being sunk from the 2825-ft. level on ore of milling grade. It is reported the shaft may be sunk deeper to assist in the extraction of this quartz. Operations have been resumed at the East Eureka. The mill is in commission and considerable development work is under way. E. Gualard has been chosen superintendent. Sinking is progressing rapidly at the Kennedy with the shaft now down about 3700 ft. With the consummation of this work extensive lateral driving will start. In the meantime production continues along normal lines. It is rumored that the last clean-up at the Argonaut was the largest in years. A good surplus is in the treasury, but no dividends are being disbursed pending settlement of the litigation with the Kennedy Extension company. Hugo and Martha Loss have petitioned the courts for a temporary injunction preventing the Kennedy, South Eureka, Zeile, Bunker Hill, Fremont Consolidated, Lincoln Consolidated, and other prominent mining companies from dumping debris into Dry, Jackson, and Sutter creeks. The defendants are also desired to appear and show cause why the injunction should not be made permanent. It is charged that deposition of tailing in these creeks has damaged the agricultural lands of the plaintiffs. Deep quartz mining is probably more active in this county at the present time than at any period in local history. This is largely due to the success attending deep exploration at the Kennedy, Argonaut, and South Eureka mines.

The Delhi Mining Co., in Nevada county, has made ar-

rangements for the completion of the five-mile flume line from Bloody Run to the Delhi mine, on Columbia hill. One mile is already in place, and the company will complete the remainder on its own account. It is expected to have the work finished by the end of next summer. Good finds were reported last week from the American Hills area in Nevada county. Cadman Bros. have found a shoot of sulphide ore in their Ophir mine. The vein is said to be 10 ft. wide, with the ore fair grade. It is thought to be the south extension of the Sierra del Oro vein. The find was made 700 ft. from the adit portal. The level is being continued to intersect the Clover Patch deposit of red gravel. A shoot ranging from 2 to 12 ft. wide is reported at the Mt. Moriah. It is stated to assay \$5 to \$10 per ton. H. Norman, J. W. Meehan, and T. Peterson, of Kennett, are the owners. Promising ore has been found near the Middle Yuba river by W. J. Nixon. The claims are owned by C. E. Harvey, of Astoria, Oregon. Six stamps of the Prudential mill are operating on ore from the 900-ft. level. Lessees are working at this point and some good ore is reported showing.

### NEW YORK

**STRONGER COPPER MARKET.—SHATTUCK-ARIZONA.—DEVELOPMENT AT ELY.**

The clearing of the Balkan war cloud and the apparent averting of the danger of a general European conflict served this week to put fresh spirit into the market, which had very nearly come to a dead standstill. The buying of copper for foreign account is said to be in very large volume and that without any concession in price on the part of the sellers. Undoubtedly this is in part due to the publication of the fortnightly figures covering the visible supply in England and on the Continent, which show a decrease of nearly 4,000,000 lb. Taking also into consideration the calculated decrease in the amount of copper afloat in transit from South America and from Australia, the world's visible supply showed a decrease of 6,250,000 lb. This is attributable to the unsettlement created by war conditions and the fact that during the past month buyers preferred to draw upon home supplies rather than make commitments, with the result that such supplies must now be replenished. Custom House clearings show a comparatively small volume of copper moving from this side to Europe during the past six or eight weeks, but the aggregate for the ten months of the current year has broken all previous records, and it may be regarded as certain that 1912 will be the largest export year the copper industry has ever had. Shipments for the ten months total 625,786,800 lb., as compared with 610,346,240 lb. for a similar period during 1911, and 537,304,320 lb. for the first ten months of 1910. The added strength shown in the foreign situation is due to the fact that, in spite of these record-breaking exports, there has, nevertheless, been no inconsiderable shrinkage in foreign supplies. If peace overtures are successful and confidence is restored abroad, an increased demand might result. If at the same time domestic consumers should abandon the hand-to-mouth policy which has been pursued during the past eighteen months, the demand for copper would be such as to undoubtedly create a further increase in price. At the moment 17 $\frac{3}{4}$ c. is the prevailing figure, with sellers resolutely refusing to make the least concession.

The record-breaking consumption of copper is a matter worthy of a great deal of study. That an enormous copper surplus should pile up with the metal at a figure that can be said only in a few instances to have equaled the cost of production, as was the case two and a half years since, only to be followed by a cleaning up of copper stocks with prices 50% higher, is one of the incomprehensible contradictory movements in business. If there could be some adequate statistical information compiled covering the actual consumption of copper—that is to say, its manufacture into the articles in which it ceases to be an article of merchandise—such figures would shed a world of light on the copper situation and would assist greatly in determining the point at which production is to overtake or pass consumption. While the mining of copper has changed radically in

its character as an industry, and has become so exclusively a field of large capital in which public participation is gained only through the stock market, yet the rejuvenation and rehabilitation of the many copper properties that could not be operated profitably during the months when the metal was selling at 12 and 13c. is a most encouraging feature. Granby, heretofore commented upon as a striking example of ability to come back, has just issued a supplementary report showing net profits for four months ending October 31. Granby is earning at the rate of \$1,680,000 per year, and has on hand a net balance of \$1,100,000 in cash and copper in excess of its liabilities. C. O. Mailloux, assistant to the president, has just completed a trip of inspection covering the properties at Grand Forks, Phoenix, and Hidden Creek, and in his report embodies the statement that the outlook at all of the properties is even better than indicated by previous estimates and figures. The Granby management is still looking for some plan that will permit the expenditure of the \$2,000,000 necessary to equip the Hidden Creek property without deferring the payment of dividends for too long a time.

The movements in Shattuck-Arizona on the Boston Stock Exchange have created a good deal of comment. The market in the shares has been an inactive one for months, and sales have recently been made as high as \$35 per share. The movement is supposed to be based upon the resumption of shipments to the Calumet & Arizona smelter. It is highly probable, however, that the market price is affected somewhat by two or three deals now in hand looking to the absorption of the Shattuck-Arizona by some of the larger interests, the deal to take over both the original Shattuck-Arizona and the Denn Arizona ground.

The foreclosure of the mortgage held by the Lincoln Trust Co. of New York, securing the bonds of the La France Copper Co., is presumed to mark the termination of the connection of F. Augustus Heinze with that property. It is said that as soon as legal requirements can be complied with, the Old Lexington mine of the La France company will be reopened. At the moment Heinze is devoting some of his energy to the Stewart property at Coeur d'Alene. Stewart is now said to be earning some \$60,000 per month, and there is talk of a dividend. The suit brought by E. J. Carter has recently been dismissed, but it is said that some serious litigation has been started by the Bunker Hill & Sullivan alleging that Heinze has been pursuing the tactics that made him famous in Butte—disregarding boundary lines underground. Market experts are much inclined to the belief that this move is one of distribution.

Nevada Consolidated, since its share control passed into the Utah Copper Co.'s treasury, has ceased to be a live issue marketwise, and news concerning that property is without any effect upon quotations. It is reported, however, by engineers recently returned from Ely, that the company has recently made an important discovery on the Veteran ground, where a large body of high-grade ore has been found in a contact vein. Details are not forthcoming, but the importance of the discovery is said to be considerable. There is a rumor that a large merger is a possible development at Ely. A deal is being put together to include in a new company the Giroux, the Gunn-Thompson holdings, and some other ground, the interests concerned being those in the Inspiration Consolidated Copper Co., consisting of Wm. B. Thompson, of Thompson, Towle & Co., Thos. F. Cole, John D. Ryan, and other leading figures in the copper world.

A possible copper merger that has been considerably talked about includes the Wolverine, the Mayflower, and the Old Colony, which lie near and in part adjoin the Calumet & Hecla in the upper peninsula of Michigan. Recent diamond-drilling on the Mayflower and Old Colony has brought most encouraging results. From assays made from drill-cores results of 25 lb. of copper per ton have been obtained. The drilling has been most thorough, some 26,000 ft. of core having been raised, and the results very carefully tabulated. Mayflower development is now considered the most important that has been made in the Lake Copper country during recent years. Followers of the Mayflower

are saying that the Ahmeek, now the spectacular producer of the Lake country, did not have so good a showing at the same period in its development. The New England faith in copper is to be renewed by an increased disbursement by the Calumet & Hecla, as it is expected that a \$15 disbursement will be made by the directors at the coming quarterly meeting. Up to the present time the Lake copper companies have distributed nearly \$3,000,000 more than was distributed last year.

### TORONTO, CANADA

#### STRIKE AT PORCUPINE.—DEMANDS OF THE MINERS.—NEW SHIPPER AT COBALT

A general strike of the union men belonging to the Porcupine branch of the Western Federation of Miners was called on November 15 as the result of a referendum vote on the question, taken on the previous day, which was stated to be practically unanimous in favor of the strike. The cause of the trouble dates back for some weeks, when five mines in the Pearl Lake area which had been paying somewhat higher wages than were given at the other mines, announced a new wage schedule making some reductions. The men thereupon appealed to the Canadian Department of Labor, which appointed a Board of Conciliation, under the Lemieux Act, to make an investigation. The Board brought in a majority report to the effect that, with one minor exception, the wages offered in the new schedule were fair and adequate, and recommended its acceptance. The men rejected the terms and submitted the question of going on strike to a vote. As a result, about 1000 men, including a number not belonging to the union, are out, and most of the mines have been closed down. The numbers on strike at the principal mines are given approximately as follows: Dome, 300; Hollinger, 300; McEneaney, 80; McIntyre, 60; Dome Lake, 60; Porcupine Lake, 50; Hollinger Reserve, 50; Plenaurnum, 30; Hughes, 40; Jupiter, 25; Dome Extension, 25; Vipond, 50; Pearl Lake, 20; Three Nations, 20. Three mines, the Pearl Lake, Three Nations, and Shumacher, have yielded to the demands of the union and work has been resumed. The Dome and Hollinger mills are running, and each has a few men at work underground. With these exceptions the entire district is tied up and a large number of the strikers have left. The Dome has succeeded in bringing in a trainload of strike-breakers, and has a force of special police closely watching the property. The roads are picketed by the strikers, who have stopped assessment work on many of the outlying prospects. Order has been generally well maintained, though one affray took place in which revolvers were drawn. Just before the outbreak of the strike A. A. Cole, mining engineer for the Timiskaming & Northern Ontario railway, after a visit to Porcupine, estimated that the gold output for 1912 would closely approximate \$2,000,000. In view of the strike, this forecast cannot be expected to be realized.

Large additions had been made to the ore reserves of the McEneaney up to the time when work was suspended, and the ore blocked out is valued at over \$800,000. On the 300-ft. level there is an ore-shoot 150 ft. long, averaging 5 ft. in width, carrying ore which averages \$50 per ton. Assessment work on the Bewick-Moreing claims adjoining the Foley-O'Brien property has opened up a large orebody with high gold content. The company's plans as regards the development of this property have not been announced. The Vipond mill closed down before the strike for alterations in connection with the construction of the 100-ton cyanide annex. The roof is being raised 5 ft., and other outside changes made, so that the cyanide machinery can be put in as soon as it arrives. Surface exploration on the Calvert has resulted in the discovery of four new veins in the schist formation, running from 6 to 8 ft. in width, and yielding good assays. The Dome Lake has cut its vein at the 180-ft. level, where it is 2 ft. wide and carries about \$40 in gold per ton. At the claim owned by W. S. Edwards, north of the Imperial an orebody 30 ft. wide has been found.

The principal feature at Cobalt lately has been the appearance of the Seneca Superior, which holds a Peterson

Lake lease, on the shipping list with an initial consignment of 34 tons, to be followed up shortly by other shipments. The success of this company has resulted in an upward movement in Peterson Lake stock. The Beaver has cut a new vein of 2 in. of high-grade ore on the 460-ft. level. This mine is now drawing ore from eight levels and is working at a depth of 700 ft., which is the deepest level in Cobalt. The General Mines Co., recently organized, has taken over the Green-Meehan power plant to furnish air to drills operating at the Red Rock. Ten of the 40 stamps of the Nipissing's new low-grade mill have been put in operation. The aerial tramway connecting the Meyer shaft with the mill is working regularly. The McKinley-Darragh has declared an extra dividend of 10%, to be paid January 1. The Casey Cobalt new mill is treating an average of 25 tons per day, the ore averaging 40 oz. per ton. There is enough low-grade ore on the dump to keep the mill running for two years. A pocket of rich ore has been found at the Lumsden on the 220-ft. level which shows a good

NATIVE SILVER FROM NIPISSING MINE.

width. On several levels pockets have been found, but hitherto have proved too short to show profits from working.

### SPOKANE, WASHINGTON

#### SESSION OF AMERICAN MINING CONGRESS.

Over three hundred delegates are in attendance at the fifteenth session of the American Mining Congress, now being held in this city, and much interest is shown. The session was called to order on Monday afternoon by Graham B. Dennis, chairman of the Spokane committee, and the remainder of the day was taken up by the addresses of welcome and the responses from the different state delegations. In the evening the president's annual address was delivered, followed by a reception on a magnificent scale to the president and officers of the Congress by the Spokane Chamber of Commerce. Tuesday, Wednesday, and Thursday are to be devoted to morning and afternoon sessions for discussion as already announced in the printed program, but arrangements have been somewhat upset by the failure of many of the speakers to arrive, and general discussion has been substituted for the papers announced in some cases. Tuesday was devoted to discussion of the protection of investors, which had been set for Friday; on Wednesday papers on Alaska and its needs were presented, followed by an open discussion. On Thursday workmen's compensation was the topic for discussion. The entertainment afforded the visiting delegates by the local members was as elaborate as it was enjoyable.

## General Mining News

### ALASKA

A Government report recently issued states that the trade of Alaska for 1912 amounted to \$45,000,000, as against \$20,000,000 in 1903, an increase of 125% in less than ten years. To this total must be added production of gold for the eight months ended August 31, amounting to about \$8,000,000. The bulk of the value of Alaska's trade at this time is represented by copper and canned salmon shipments. For a sparsely populated country which has labored under many difficulties, these figures are remarkable.

#### FAIRBANKS

The 5-stamp Joshua Hendy mill has been started at the Pioneer mine, and there is plenty of ore and water for milling purposes. At the Bluebell lode claim, a shaft is being sunk on a vein two feet wide. The shaft at the Cotton Blossom is down 80 ft., and at 60 ft. a lode was found to be 28 ft. wide. Water has given trouble, and a hoist will be installed. The mill on Ester creek is almost finished. It consists of a 40-ton ore-bin, crusher, automatic feeders, two Nissen stamps, with room for others if necessary. At 85-ft. depth the vein in the claim is 7 ft. wide. The News-boy mill crushed 225 tons of ore valued at \$3750. Two stopes are being opened at the 215-ft. level. At Iditarod the Mohawk syndicate on Flat creek has arranged to sell its property to the Yukon Gold Co. for \$106,000.

#### JUNEAU

The Alaska Mexican, Alaska Treadwell, and Alaska United companies have declared dividends of 30c., \$1, and 50c. per share, respectively, payable on November 29 at San Francisco. During October the Treadwell mills worked 30.45

MERRILL PRECIPITATION PRESSES AT TREADWELL CONCENTRATE PLANT.

days, and crushed 77,924 tons of ore, producing \$193,489 from amalgamation, and cyanide treatment of 1680 tons of concentrate. The net profit was \$101,051. Development covered 725 ft., and the stock of broken ore decreased 5605 tons.

### ARIZONA

#### COCHISE COUNTY

(Special Correspondence.)—Foundations are being laid for a new mill at the Commonwealth mine, at Pearce, which is being developed by a subsidiary company of the Montana Tonopah Mines Co. E. A. Collins is superintendent. The mine has been opened to below 450-ft. depth, and reserves are estimated at 289,543 tons worth \$1,783,100. Two mills have worked at the property, one being destroyed by fire in 1900, and the second shut down in 1904 on account of a cave-in at the mine. The new mill, to crush an andesite ore carrying gold and silver, will consist of the following: Thirty 1500-lb. stamps crushing through a coarse screen, three Hardinge 8-ft. mills, Dorr classifiers, two 5 by 22-ft. tube-mills, eight Pachuca vats 15 by 38 ft., four Oliver filters, and probably zinc-dust precip-

itation. The mine makes about 900,000 gal. of water daily. Pearce, November 20.

According to recent statements, the Guggenheim interests have come into Arizona by the purchase of the interest of the Development Company of America, including the Christmas, Imperial, Congress, and other properties. It is also stated that the Tombstone Consolidated properties are included, and probably the Poland mine. Large bodies of silicious ores are regarded as of great importance to the smelting interests of Arizona.

#### GILA COUNTY

There is nothing fresh to report from the Miami Copper Co., work at the mine and mill being on the usual lines. At the Inspiration large gangs of men are cutting grades and tunnels for the railroad. The Sulphide tunnel of the Live Oak portion of the Inspiration is being enlarged for installation of electric haulage. A No. 24 Star drill rig has been erected at the Southwestern Miami. The Prospector drill-hole is over 140 ft. deep. At the Sho Me property men are completing assessment work; a 50,000-gal. tank is being constructed, and it is probable that churn-drilling will be started soon.

#### MOHAVE COUNTY

The Tom Reed Gold Mines Co. has paid dividends equal to 7% for November, amounting to \$65,000. The monthly output has averaged \$120,000 of late. A new orebody has been opened about 500 ft. from the old ore-shoot. Improvements are being made to the cyanide plant. R. N. Dickman is at the Frisco mines, at Union Pass, examining the property and planning the new mill.

#### SANTA CRUZ COUNTY

The Phelps-Dodge company has acquired the Humboldt group of copper-silver claims for \$10,000, and they will be opened at once. Ore will be sent from Patagonia to the Copper Queen smelter at Douglas.

#### YAVAPAI COUNTY

The adit being driven by the Arizona-Portland Mines Co. is now in 160 ft. Over 5000 tons of ore has been shipped from the Commercial mines at Copper Basin. Ten tons of silver ore, averaging \$300 per ton, was sold by the owner of the Bill Arp mine in the Turkey Creek district. Copper ore has been opened in the Sink to Rise claim at a depth of 25 ft., which is something new, as this is a gold mine.

#### YUMA COUNTY

The lower Eagle adit of the Arizona-Empire mine, 10 miles above Parker, continues to open high-grade copper ore, which has averaged 52% of copper. Ten tons of ore daily is to be shipped for a month, after which the tonnage will be 20 per day. Shipments are also being sent to the Swansea smelter from the American Eagle mine. The main shaft is down 300 ft., and with the reserves of ore it is probable that a concentrating plant will be erected.

### CALIFORNIA

#### ELDORADO COUNTY

A large deposit of gravel has been uncovered at the Maynard claim of the Landecker mine, 1½ miles from Placerville, and averages \$3 per ton. Part of the property has been worked since 1852, but the present find is in unprospected ground, covering 200 acres. At the China Hill mine, 6 miles from Placerville, ore worth \$40 per ton has been cut in a vein 6 ft. wide, in an adit 130 ft. below the outcrop. The ore carries sulphides, and there is a stamp-mill on the property.

#### INYO COUNTY

Work is again under way in the Chidago district after a long period of idleness. The St. Ives is being developed by the Lone Star company of Goldfield, Nevada. The main shaft is being straightened and repaired. Lessees have shipped ore worth over \$30 per ton and left a dump of 400 tons averaging \$15 per ton. Ore reserves are estimated at \$40,000. On the whole, prospects are fairly good at this mine.

## NEVADA COUNTY

At the Morning Star mine, at Badger Hill, rich ore has been opened in a cross-cut. It is highly mineralized, and J. Curnow, superintendent, considers the discovery the best ever made at the mine. Salmon Brothers are also mining good ore in their claim at Badger Hill. The Supreme Court has upheld the Nevada county court's finding for the Champion Mine Co., which was sued by the Champion Gold Mining Co. to enforce a contract for the purchase of the former's mining claims in this district.

## SACRAMENTO COUNTY

The Natomas Consolidated company has commenced to build its No. 7 dredge, which, when completed, will work in Blue ravine, about four miles east of Folsom. The dredge will be of steel, 134.7 ft. long, 46.5 ft. wide, and 9.5 ft. deep. There will be 98 buckets of 9-cu. ft. capacity each, and allowing for usual stoppages, the monthly capacity should be about 155,000 cu. yd. A revolving screen 7 by 35 ft. will separate the fine gravel from the large stones. The bucket ladder will be able to dig from a depth of 58 ft. Blue ravine has produced a good deal of gold in the past. The drift-mining operations which were being conducted there had to be abandoned because there were no proper means of handling water. The new dredge may be finished by April of next year. The company is to reclaim and develop 90,000 acres of land near Sacramento and has arranged with the Oro Electric Co. for a water right sufficient to irrigate this large holding.

## SAN BENITO COUNTY

It is reported that a large deposit of cinnabar has been discovered near Hernandez in this county. Samples of ore have yielded a high percentage of mercury.

## SAN BERNARDINO COUNTY

The United Greenwater Copper Co., in which C. W. Schwab is interested, has taken a 49-year lease on the mining properties of A. Landwehr, at Dale, for \$2,000,000, with the agreement to purchase at any time during that period. There are 38 claims in all, carrying ores averaging \$20 per ton. Royalties to A. Landwehr will be from 3 to 50% of the gross value of the ore mined and treated on the property, and when treated elsewhere he will receive 50% of the net receipts.

## SIERRA COUNTY

The Alaska company, at Pike City, is employing 80 men. Rich ore is being mined just now. The October output was between \$40,000 and \$50,000 from the 40-stamp mill. At the Wisconsin drift gravel property, underground surveys are being made for a new scheme of development. Several nuggets were recently obtained from the True Blue Extension quartz claim. The Omega gravel mine has been acquired by new people, and the adit will be driven 1000 ft. farther. During the past three weeks there have been excellent falls of rain and snow in the Sierras, making a revival of mining generally.

## SISKIYOU COUNTY

The coal mine near Snowden which has lain idle for the past five years will be reopened soon, pumping having been in progress for two months. E. C. Gamble is manager.

## COLORADO

## CLEAR CREEK COUNTY

Work has been started at Silver Plume for the Edison works, which will employ large rolls and concentration, probably as a custom mill for the district. At the drill-hole on Griffith mountain efforts are being made to recover the lost tools which have been interfered with by caving of the hole. Lessees at the Capital mine are busy and making regular shipments of ore.

## GILPIN COUNTY

Settlements for ore from the Pittsburg mine have returned \$200, \$168, and \$81 per ton, respectively. This ore was from the 900-ft. stopes. The Topeka mine is producing 7 cars of ore per day. An electric hoist has been installed by the Bezant Mining Co. A shipment from the

War Dance averaged 2.1 oz. of gold and 3.26 oz. of silver per ton. At the Wild Cat, on the 100-ft. level, good lead and zinc ore has been opened.

The Buckley property, recently taken over by R. P. Morris, E. F. Colbon, J. R. Letcher, J. A. McAlister, Newton Farr, and others, is developing in a satisfactory way. B. T. Lloyd, the general manager, reports that a large amount of gold-silver ore is being developed, some of which assays as high as \$400 per ton.

## LAKE COUNTY (LEADVILLE)

Car shortage continues to hamper shipments from the district and seems to be getting worse. The opinion is that until farmers are supplied with cars the miners will not be relieved. During October the D. & R. G. railroad handled 300 less cars than in September.

The 'interior' shaft in the Yak tunnel, being sunk to develop the Diamond and Vega properties, is down 150 ft. below the tunnel level, and will be sunk another 100 ft. At present there is a heavy flow of water hampering work.

## SAN MIGUEL COUNTY

The United States Government has charged the Telluride Power Co. with taking 122,434 ft., board measure, of lum-

CAMP BIRD MILL.

ber from land in Idaho, between January 1910 and December 1911. The company made 300 poles out of the lumber. Damages are assessed at \$3575.75. On November 18 the deputy sheriff sold all the property and rights of the power company in Colorado, Utah, and Idaho, at Telluride, for \$6,460,000. By this transaction the Telluride Power Co. is dissolved, and a new corporation will have control.

## TELLER COUNTY (CRIPPLE CREEK)

Another meeting of the directors of the Roosevelt tunnel is to be held soon, while data are being secured as to the usefulness of another drainage tunnel 500 ft. below the Roosevelt tunnel. On November 6 water in the Mary McKinney shaft stood at 126.7 ft. below No. 8 level, or at an elevation of 8625.6 ft., showing an approximate total decline of water at that point of 217 ft. Water is entering the 1000-ft. level of El Paso at about 500 gal. per minute at an elevation of 8450 feet.

The Cresson shaft on Raven hill is to be sunk another 100 ft. Sub-lessees have started work at the Requa-Savage mine. As soon as the Nichols shaft of El Paso is in working order the main shaft will be cleaned to the level of the Roosevelt tunnel. This shaft was put through from the tunnel when work was going on in the heading of the drainage bore. On the 1275-ft. level of the Isabella, 700 ft. south of the shaft, a large orebody has been opened. Since April 1908 about 320,000 tons of ore has been treated from the dumps at Stratton's Independence.

## IDAHO

## SHOSHONE COUNTY

The suit of E. J. Carter, of Spokane, against F. A. Heinze

and others of the Stewart company has been compromised and settled out of court, whereat there is rejoicing among shareholders. The company has about \$400,000 in reserve, and dividends are now expected.

The Hecla Mining Co. has paid a 2c. dividend amounting to \$20,000, making \$250,000 for the current year, and a grand total of \$2,600,000.

The introduction of electric power into the Carter district, in the east Coeur d'Alene district of western Montana, is resulting in more active work. A transmission line 50 miles long is being constructed from Thompson Falls by the Iron Mountain Co., and other companies are arranging for a supply. The line is expected to be ready early in December. The Iron Mountain company is employing 70 men; it has a 150-ton mill to treat its ores carrying zinc, silver, and lead. The main adit is in 6400 feet.

## MONTANA

### LINCOLN COUNTY

(Special Correspondence.)—The Big Eight mine, south of Troy, is shipping another car of ore this week, and expects to ship another within the next two weeks. The auto-truck intended for use in hauling ore to town has been found incapable of climbing the big hill, and will be shipped back to Spokane.

Libby, November 21.

## NEVADA

### ESMERALDA COUNTY

Some good samples of silver-lead ore have been on view in Tonopah during the past week, coming from the Thorn-dyke district, 15 miles south of Tonopah, and near the railroad to Goldfield. Quite a small rush has taken place, and prospects are decidedly encouraging. J. Golden recently secured control of the Original Klondyke property, and in addition to development has let several leases on it. About 150 tons monthly are being shipped from the property. Lee and Watson have opened good silver-lead ore about a mile from the Golden property. One vein is 8 ft. wide returning from \$20 to \$70 per ton, and another is 5 ft. wide worth from \$30 to \$60 per ton. Leases have been granted on the property. This district is near the railroad, water, and electric-power line.

At the Florence Goldfield mine high-grade ore is being shipped from the vein which was first opened at the 250-ft. level, and which has been also developed between No. 5 and 7 levels. The 1200-ft. station is being excavated, and the shaft is down to 1270-ft. depth. The Bonnie Clare mill, which is treating ore from the Jumbo Extension, has started again, after improvements to the crusher, and the installation of five more concentrating tables. The daily capacity of the mill is now 100 tons. A shipment of ore worth \$40 per ton is being sent out from the Vernal property near Diamondfield. Development at the Silver Pick is encouraging. Near the Mohawk a seam of quartz and talc, from 6 to 36 in. wide, was cut on a prospecting level at 85-ft. depth. A cross-cut on the 130-ft. level also passed through it, but here it was low grade. At 260-ft. depth the vein is large, though much disturbed, and a raise is now up 40 ft. in poor ore, yet similar in appearance to the Mohawk. There is nothing fresh from the Consolidated property. At the mill all is in good order, and high extractions are being made at the concentrate plant.

The Nevada Coal & Fuel Co., which owns a coal mine near Coaldale, on the Tonopah & Goldfield railroad, has started regular shipments from its property, which contains the only coal mine in Nevada. A shipment of five cars will be sent to Goldfield, and in time the mine may supply the needs of the mining centres.

### EUREKA COUNTY

(Special Correspondence.)—Foundations for the new mill of the Buckhorn Mines Co. are now being laid. The ore being soft, there will be no stamps in this mill, which was designed by J. W. Hutchinson of the Goldfield Consolidated company.

Goldfield, November 20.

The Aurora, one of the most famous old mines of the desert, is being reopened by a syndicate headed by Charles E. Knox, of Tonopah, and Jesse Knight of Salt Lake City. The property was examined recently by J. E. Spurr and assistants for the Tonopah Mining Co., but that concern decided not to undertake to reopen the mine. Mr. Spurr's report, by contract, was given to the mine-owners, and it was upon it that the new syndicate was organized.

### LYON COUNTY

For the seven days ended November 14 the Thompson smelter received 6080 tons of ore, 3148 tons coming from the Nevada-Douglas, and 2288 from Mason Valley. Ten carloads of matte was shipped during the same week. During October the smelter dealt with 27,319 tons of ore producing 1,646,000 lb. of copper, making a total of over 13,000,000 lb. since January of this year.

During October, Hamilton & Pollard's mill at Silver City crushed 800 tons of ore, and the three cyanide plants worked full time. While there is no mining operation of unusual note at this centre, lessees and claim owners are mining a considerable amount of ore of fair grade.

### NYE COUNTY

(Special Correspondence.)—Electric power is a great boon to Tonopah, and it is hard to imagine very profitable work without it, and any interruption of supply shuts

MAIN STREET, TONOPAH.

everything down. On October 29 a short-circuit in the sub-station here started a fire which damaged the plant to a value of \$17,000. Since then the Nevada-California Power Co. has worked hard to get the building and plant in order; but on November 23, at 10:30 a.m., a 'short' was caused by something being dropped on the high-tension wires, and a big fire started again. It may now cost \$30,000 to fit the station properly. All the mines were closed down for 5 hours, but in 24 hours connections were made again for full power and light.

At the pumping station of the Tonopah Water Co. a man was electrocuted on November 22 through a pipe coming in contact with wires carrying 6600 volts. He lived about ten minutes after receiving the shock.

The new mill at the Belmont is working well and shows a general high extraction. Generally the mine is opening well, especially on the 1166-ft. and No. 12 levels. The West End mill was overhauled on November 22, one tube-mill being relined and other repairs made. The company shipped during the week 21½ tons of concentrate and 23 bars of bullion. October profits amounted to \$33,864. The North Star has shipped a carload of ore from between the 800 and 950-ft. levels, where the ore is from 16 to 30 in. wide. From the Extension, 40,144 oz. of bullion, worth \$31,715, was shipped during the week. Two cars of ore have been sent to the Belmont mill at Millers, from the Merger mine. This ore will average \$40 per ton, and it is expected that 300 tons per week will be sent to the mill.

Production from all the mines during the week ended November 23 was 10,554 tons, valued at \$263,850. The *Tonopah Miner* has issued a pamphlet dealing with the district, which states that to September 30 the bullion pro-

duction of the district was \$55,143,248, and dividends totaled \$14,703,314.

Tonopah, November 25.

At Manhattan the Big Four company is pushing development on the 200, 300, and 400-ft. levels, and material for the new mill is arriving from Tonopah, a distance of 45 miles across the desert. A flow of water amounting to about 144,000 gal. has been tapped in the northeast drift on the 250-ft. level of the Earl. From the Pittman-Finlayson lease at the Litigation Hill Merger, 300 tons of ore is being treated at the Associated and War Eagle mills. The White Caps is sending a regular tonnage to the former mill. About 100 tons of ore is to be milled from the Muskett-Wittenberg lease on the Manhattan Consolidated.

The Tonopah Mines Corporation has completed the purchase of 21 claims owned by the Little Tonopah Mining Co., adjoining the Merger mine, for \$250,000. A large shaft will be sunk to 1000 ft. in the Sagebrush claim. The Tonopah Mines Corporation is capitalized at \$300,000, with J. G. Kirchen as president; Seeley W. Mudd, vice-president; Key Pittman, secretary and treasurer.

Surveyors are at work for the Southern Pacific Co. near Manhattan, and it is thought that the line will pass within a few miles, if it does not enter the town.

## UTAH

### SALT LAKE COUNTY

At the Alta Consolidated, at the Brooklyn shaft, connection will soon be made between the bottom level and a raise from the lower adit level. The raise has been in two to four feet of high-grade ore. In a drift started west several mine-cars of ore assaying 28.4 oz. of silver, 42.6% lead, and 0.03 oz. of gold were broken out. This orebody is 1500 ft. from the famous deposit in the Emma property, from which \$7,000,000 was mined years ago.

### SUMMIT COUNTY

Until the two additional roasting furnaces for the Mines Operating company's plant at the Ontario mine are finished, work at the mine and mill is almost at a standstill. The furnaces will have a capacity of 40 tons each, and should be ready in a few days. The Augustin process being tried in this mill is a revival of an old method by which silver in the ore, when roasted with common salt, is converted into a chloride, and a strong solution of salt will dissolve the chloride, which will be precipitated as metallic silver on copper. In 1874 the first mill built in Park City was the Marsac, and in 1875 three mills were treating the Ontario ore. In 1877 the Ontario mill was remodeled, as was also the Marsac, in 1880 and 1882, to the Russell process. In 1890 concentration was tried and remained the process until recently.

Ore shipments during the week ended November 23 were 687 tons from the Daly West, 539 from the Silver King, 339 from Daly-Judge, and 42 tons from King Consolidated. The Daly West recently received as an express 'package' a 12,000-lb. air-compressor which was needed in a hurry.

### TOOELE COUNTY

Regular ore shipments are being made from the old Stockton district. From the Bullion Coalition mine about 1000 tons per month are sent out by the company and lessees, while the Ben Harrison, Cyclone, Galena King, Honorine, and others are also shipping ore.

## WASHINGTON

### FERRY COUNTY

(Special Correspondence.)—In the Superior Court in and for Ferry county, in the case instituted by the Quilp Gold Mining Co. v. the Republic Mines Corporation and J. L. Harper, wherein the plaintiff, alleging that the defendants were and had been extracting and removing ore from the Quilp lode claim, owned by the plaintiff, applied for an injunction to restrain the defendants from trespassing and taking ore therefrom, as mentioned in these columns on October 26. The trial lasted eight days, the plaintiff testifying that, although the defendants had followed their own vein from its apex in the Surprise quartz lode claim,

they had crossed their east side-line and entered the Quilp ground and extracted and removed ore from another and separate vein within the vertical lines of the Quilp lode claim. The defendants testified that they had followed the Surprise vein from its outcrop, on its pitch downward, through and across the westerly vertical side-line of the Quilp ground, to the 700-ft. level; that the 'separate' vein alleged in the plaintiff's testimony is one and the same as that which had been followed by the defendants from the surface, but that it had been partly dislocated and separated within the vertical side-lines of the Quilp claim by

REPUBLIC, WASHINGTON.

a fault, which had been disclosed on the 400-ft. level and afterward on No. 2, 3, and 5 levels of the Surprise workings. The court, after five days' deliberation, decided that, upon an order to show cause why an injunction should not be issued, it was ordered that the defendants and others are enjoined and restrained from entering upon any part of the vein within the vertical lines of the Quilp lode mining claim or taking any ores or minerals therefrom or trespassing thereon. The plaintiff was required to file a bond with the clerk of the court, signed by a responsible surety company, to be approved by the clerk of the court, in the sum of \$15,000. The case so decided is preliminary to one for damages, on account of ore claimed by the plaintiff to have been extracted and removed from the Quilp ground, the property of the plaintiff, the date for the trial of which has not yet been set.

Republic, November 22.

H. J. Lefevre and Jasper King, of the Walla Walla M. Co., have bought the land of the Keller & India Con. Smelting Co., sold at public sale by J. C. Cody, the receiver. Mr. Lefevre bought the smelter and water-rights of this company at a tax sale last year.

### SNOHOMISH COUNTY

Rich copper ore has been found in the mine of the Glacier Peak M. Co., 27 miles from Lucerne. Underground development amounts to about 800 ft. of work. Henry Noll is vice-president of the company.

### SPOKANE COUNTY

The American Mining Congress opened at Spokane on November 25. There is a large attendance of delegates from Alaska, British Columbia, and nearly every state where mining is engaged in. Discussions will cover control of natural resources, Alaskan coalfields, more liberal application of mineral land laws, and a new law for states to provide compensation to injured workmen, the cost to be taxed on the commodity produced.

### STEVENS COUNTY

Machinery is being installed in the Chewelah Copper King mine, and the property will be on a shipping basis soon. S. P. Domer is manager. Mark Mitchell, who is leasing the Blue Star, has installed a pump in the main shaft of the property.

## Personal

Professional men are invited to send news of their engagements and travels. Such news is interesting to friends.

GEORGE E. FARISH was in Denver recently.

LOUIS DECOTO has returned from Colombia.

W. C. RALSTON has returned from Los Angeles.

L. D. GODSHALL was at Kingman, Arizona, recently.

A. CHESTER BEATTY was in San Francisco on Friday of last week.

CHARLES BUTTERS was in Virginia City during the week and has gone to Tonopah.

EUGENE P. KENNEDY was married to Miss Keenan in San Francisco on November 26.

E. RAMMELMEYER has gone to Oberwalten, Saarnen, Switzerland, for several months.

MORTON WEBBER has gone to Tennessee and will proceed to Mexico by way of New Orleans.

A. B. STEPHENS has returned to El Tigre, Sonora, after a six months stay at Mineral Hill, Nevada.

SAMUEL PRICE, Mining Commissioner for Ontario, has resigned, and has been succeeded by T. E. GODSON.

NORMAN C. STINES returned from Siberia on Monday and will make a short stay in San Francisco before proceeding to London.

A. HULSHOFF-POL is visiting metallurgical plants at Goldfield and Tonopah and expects to reach San Francisco by December 5.

H. FOSTER BAIN, D. W. BRUNTON, C. W. GOODALE, and J. W. MALCOLMSON are at Spokane attending the American Mining Congress.

CURTIS H. LINDLEY has returned from Kellogg. He was elected an honorary member of the International Law Association at its recent meeting at St. Paul.

T. J. GRIER, superintendent of the Homestake Mining Co., has returned to his duties after a six months' absence in eastern Canada, recuperating from an illness.

R. H. FLAHERTY, head of the exploratory staff of the Mackenzie & Mann interests, has returned from an extensive trip along the eastern side of James and Hudson bays.

OLD STUDENTS of the Freiberg Bergakademie will meet on December 20 at 7 p.m. at the Hofbräu Haus, Broadway and 30th street, New York City. All Freiberg students are urged to be present.

C. H. MACNUTT was in San Francisco during the week in the course of an extensive tour of inspection of the principal mining districts of this country, and has gone to Los Angeles on his way to Arizona and Mexico.

## Obituary

ISAAC COPELAND, of Sierra county, died at Berkeley, California, November 15.

C. KAUFMAN died in London, early in September, following a serious operation. Early in life he went from California to London and thence to Coolgardie, where for many years he was a prominent figure in the promotion and management of mining enterprises, the Golden Horse-Shoe among others.

DAVID D. DEMAREST died of pneumonia at his home in Berkeley, California, on November 21, aged 88 years. Born in New Jersey, he came to California with the earliest pioneers and settled at Angels Camp, where he engaged in the manufacture of machinery. For over a half-century he lived there, conducting at the same time the D. D. Demarest Co. in San Francisco, until eight years ago, he retired from practice and removed to Berkeley. A pioneer and well known in the manufacture of mining machinery on the Pacific coast, many of the largest mills along the Mother Lode were built at his works.

## Quarterly Report, Ray Consolidated Copper Company

The quarterly report of the Ray Consolidated Copper Co. shows a gross production of 9,295,818 lb. of copper contained in concentrate for the quarter, or an average monthly production of 3,098,606 lb., as compared with 2,374,314 lb. for the first and 2,984,024 lb. for the second quarter. The total production for the first nine months of the year was 25,370,835 lb. During the quarter the total net tonnage of ore treated at the mill was 429,411 tons, as compared with 374,609 tons. Of the tonnage treated during the quarter, 68% came from the territory tributary to No. 1 shaft and 32% from the No. 2 shaft. Of the total, 24% was produced from development work. The average daily tonnage for the quarter was 4667 tons. An average rate of 5000 tons per day was reached during the quarter and maintained during the month of September.

The average assay of the ore treated during the quarter was 1.6147%, as compared with 1.72% for the preceding quarter. The lower grade of the ore, amounting to about 0.10%, taken together with the fact that the tonnage was still derived in large part from the upper levels of the mines and therefore contained considerable quantities of oxidized material, is reflected in a somewhat lower percentage of extraction applying to the third quarter than to either of the previous quarters of the year. The average extraction for the quarter was 67.026%, as compared to 69.37% for the previous quarter. The average extraction for the first nine months of the year has been 68.35%. The total production of concentrate for the quarter was 25,926 tons, containing an average of 17.93% copper. The ratio of concentration was 16.56 tons of ore into one ton of concentrate. The average cost per pound of net copper produced during the quarter, after allowing for smelter deductions, and after crediting the earnings of the Ray & Gila Valley railroad against operating costs, was 10.027c., as compared to 9.954c. for the preceding quarter. The average cost per pound so derived for the first three quarters is 10.047c. This cost includes all operating and general charges, as well as 12½c. per ton for the second and third quarters, or approximately 0.6c. per pound on the third quarter's production, for the extinguishment of mine development expenses.

The constant improvement in the operating costs and conditions is shown by the fact that on a recovery of 21.65 lb. copper per ton of ore treated for the quarter under discussion, as compared to 23.9 lb. for the previous quarter, the per pound cost of production increased only very slightly. The deficiency of over 2 lb. per ton in recovery is, of course, because the ore contained approximately 2 lb. less copper per ton than it did for the previous quarter, and was at the same time somewhat more difficult to concentrate on account of its oxidized content, as previously explained.

The financial results of operations for the quarter were as follows, the disbursed earnings of the Ray & Gila Valley railroad being included under the heading of operating profits: Direct operating profits for quarter, \$640,748; miscellaneous income, rents, etc., \$9965; total net profit for the quarter, \$650,713. These earnings are computed on the basis of 17.13c. per pound for copper, or approximately ½c. per pound less than was actually received for copper sold during the period. The total net earnings for the first three quarters of the year were \$1,497,703.83. During the entire nine months the copper production has been carried at less than the market price in order that the inventory price of copper in transit might be brought down to 12½c. per pound. The entire stock of copper due for delivery from the refineries remained unsold.

During the period the sixth section of the Hayden plant was put in operation, and the seventh section is now well along toward completion, leaving only one to finish, and this last one is also partly completed, all the material and apparatus required being on the ground. The power-plant and all other accessories are completed, with the exception

of unimportant details, and on the whole the additional expenditures necessary to finish the entire plant will be comparatively small. At the mines the installation of the new compressor at No. 1 shaft has been completed and the plant at that shaft is now finished. The plant at No. 2 shaft is complete, with the exception of the installing of an additional crusher and set of rolls in the coarse-crushing plant at that point. The surface improvements, including hoist, ore-bins, crushing plant, etc., at the No. 3 shaft on original Ray Central territory, are about 50% completed, and all the material necessary to finish them is on the ground ready for assembling. The work of sinking this shaft has progressed more slowly than was expected. This has been due largely to the fact that this shaft is deeper than any workings in the vicinity and is therefore draining the entire surrounding territory, and as a consequence experienced more difficulty with handling water than was anticipated. At the end of the quarter there remained 60 ft. of sinking to complete this shaft. It should be finished in November and production of ore from the relatively high-grade orebody in Ray Central territory will be started in December, or in any event not later than January 1.

Development work in all parts of the mining territory progressed satisfactorily during the quarter, and a total of 37,715 ft. was driven in driving, raising, and sinking. This brings the total workings in the mines at the end of September up to 264,000 ft., or about 50 miles. The rate of tonnage production has been somewhat disappointing, although approximately in accord with the prediction in the last quarterly report, where it was stated that it was expected that a rate of 5000 tons per day would be reached in August. This rate was reached toward the end of August and, as previously stated, maintained during the month of September. As additional stoping ground is now becoming available, it is expected that the rate of tonnage increase will be somewhat more rapid during the fourth quarter than it has been in the immediate past. The grade of ore produced during the quarter was not as high as expected, but the reasons for this were operating rather than physical ones. Certain stoping areas expected to produce considerable tonnages of good-grade ore did not become available for actual work as rapidly as anticipated, and it was necessary, as a consequence, to produce the major part of the tonnage from areas previously worked near the upper zones of the ore deposits, and in orebodies known to be low grade. All conditions pertaining to the operations of the properties as a whole, including the labor situation, continue to be generally satisfactory, except as to the grade of the ore, and this is now improving, and the outlook is that it will increase to an average of nearly 2% by January 1.

## Company Reports

### CONSOLIDATED MERCUR GOLD MINES CO.

This company is capitalized for \$1,000,000, in shares of \$1 each. It operates an old mine in the Camp Floyd mining district, Mercur, Utah, which is now about exhausted. Prospecting for new ore was continued throughout the year. A total of 3657 ft. of dead work was done, at a cost of \$17,498. Some new ore was found, which served to prolong the life of the mines a number of months, but no really important discoveries were made, and at this time the ore reserve is seriously depleted. Unless something new is found, the duration of operations is now a matter of only a few months. A number of properties have been examined during the year, in the effort to find a new mine at which the company's present equipment might be utilized, but none of them came up to requirements. During the year ended June 30, 1912, 67,816 tons of base ore, 119,776 tons of oxidized ore, and 14,060 tons of tailing was milled, a total of 201,652, or an average daily tonnage of 560. This had an average gold content worth \$3.27 and the tailing averaged \$0.82 for the year. The average operating cost for the year was \$2.42 per ton, corresponding to an op-

erating profit of 3c. per ton treated, or 31c. per ounce of gold produced. This, with receipts from other sources, corresponds to total net earnings of \$11,047 for the year. During the year a dividend of \$30,000 was paid. The last previous dividend was paid December 19, 1906, including which the disbursements were \$1,205,000, hence the total dividends to date are \$1,235,000. Adding to the above the amounts paid by the old Mercur and De La Mar companies prior to their consolidation, the grand total of the dividends paid out of the property of the Consolidated Mercur Gold Mines Co., is \$3,415,313.

The segregated milling cost was as follows:

	Per ton.
Crushing (201,652 tons).....	\$0.114
Roasting (67,816 tons).....	0.857
Classifying and settling (159,403 tons).....	0.051
Filtering (49,377 tons).....	0.180
Leaching (152,275 tons).....	0.545
Precipitating .....	0.072
Refining .....	0.046
Assaying .....	0.015
General expense .....	0.065
Total .....	\$1.097

The number of tons of sand and dry ore leached during the year was 152,275. The consumption of chemicals was 0.73 lb. cyanide per ton and 15.27 lb. lime per ton. The lime is burned on the premises, and is low grade, so that the consumption was less than 15.27 lb. of pure lime per ton. The leaching cost was as follows:

	Per ton.
Labor .....	\$0.188
Cyanide .....	0.184
Lime .....	0.029
Other supplies .....	0.031
Power .....	0.017
Water .....	0.025
Total .....	\$0.474

The financial statement for the year ended June 30, 1912, is as follows:

Gross value of gold produced.....	\$494,133.65
Receipts from other sources:	
Gold Belt Water Co., dividends..	\$3,300.00
Ground rent .....	570.30
Unclaimed pay checks.....	75.68
Sale of Manning assay office....	25.00
	3,970.98
Total revenue .....	\$498,104.63
Less operating expenses:	
Mine .....	\$263,658.87
Tailing dumps .....	2,414.44
Mill .....	221,193.11
Manning taxes .....	26.01
Furn loss .....	15.13
Total cost .....	487,307.56
Net earnings for the year.....	\$10,797.07
Plus proceeds sale Fairfield lot....	250.00
	\$11,047.07
Balance from last annual report...	84,951.97
	\$95,999.04
Less depreciation written off:	
Stores account .....	\$6,619.17
Manning Leasing Co. stock.....	1,620.23
	8,239.40
	\$87,759.64
Less dividend No. 27.....	30,000.00
Balance of assets, June 30, 1912...	\$57,759.64

COPPER EXPORTS from Chile for the first 7 months of 1912 show an increase of 3400 tons over the corresponding period in 1911.

## Concentrates

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

THE first commercial arc-lighting central station was installed in 1879.

TO the simple alloys of copper and tin which are free from zinc, a considerable amount of phosphorus may be added without causing any harm; but when zinc is present, great care must be taken in the amount that is added.

WIRE is said to have been 'killed' when it is given sufficient tension to produce a permanent set. In other words, when the elastic limit of the material has been exceeded.

IN the copper-rolling mill it is customary to coat the sheets of copper with an emulsion of guano before they are annealed. This causes the oxide to leave the surface when it is plunged into water, and, accordingly, a clean surface is produced.

AIR-LIFTS under ideal conditions of design and operation may be regarded as perfect expansion engines, the air escaping at a pressure equal to that of the surrounding atmosphere. For this reason the efficiency of the air-lift does not decrease with increase of altitude.

GOLD and silver are always found together. At Kalgoorlie alluvial gold has been found which assayed 999.0 parts of gold and 0.9 part of silver per 1000. At the Rio Plata mine in Mexico the cyanide bullion assayed 982.0 parts of silver and 0.2 part of gold per 1000.

AN excellent cement for leather belting is composed of 2 parts pitch, 4 parts (by weight) of India rubber, 1 part shellac, 2 parts linseed oil, and 16 parts gutta percha. The several ingredients are cut into small pieces and afterward melted and mixed over a slow fire. The cement should be used while hot.

A ROUGH blue-print frame that will give satisfaction consists of a sheet of heavy plateglass and a blanket; the blanket is laid in two or three folds upon a table top or other plane surface; the blueprint paper is placed on top, face up, and then the tracing to be printed. The weight of the plate glass is sufficient to hold the three in contact.

ADSORPTION has been defined as "the adhesion of the molecules of gases or dissolved substances to the surfaces of solid bodies, resulting in a relatively high concentration of the gas or solution at the place of contact." Losses of metal from adsorption in treatment plants where milling is carried out in cyanide solution are by no means insignificant. To minimize such losses cement flooring is essential; and arrangements should be provided for washing down the floors and for the return of the solution of water used to the mill-circuit.

SAMPLING gold bullion has led to many discussions, and in a paper on this subject, recently read at the Eighth International Congress of Applied Chemistry, F. P. Dewey, assayer at the Mint, summarizes the following conclusions in sampling deposits of miscellaneous gold bullion weighing over 300 oz.: There are various cases where either a chip or drill-sample may be satisfactory; there are cases where a drill-sample is better than a chip-sample; where an assayer is acquainted with the metal, he may accept a chip or drill-sample; on unknown bullion, it is unsafe to accept any sample except a properly prepared dip-sample; and, in many cases, particularly of cyanide-bullion, the composition of the metal interferes with the actual assaying, and the bullion must be refined before the gold can be accurately determined.

## Book Reviews

Any of the books noticed in this column are for sale by, or can be procured from, the MINING AND SCIENTIFIC PRESS.

**ELEMENTS OF DRAWING.** By George F. Blessing and Lewis A. Darling. 174 pp., index. John Wiley & Sons, New York. For sale by the *Mining and Scientific Press*. Price \$1.50.

This book has been especially prepared for beginners who intend to take a course in engineering or commercial draughting. So many books of similar nature are already available that it would seem to be a difficult task to add anything to the existing literature on the subject. The use and care of the usual instruments, how to sharpen pencils, lettering, draughting room practice, conventional hatchings, free-hand sketching, and isometric projections are all treated at length. The book is copiously illustrated, even to the extent of showing how to make holders for ink bottles.

**MACHINE DESIGN: HOISTS, DERRICKS, CRANES.** By H. D. Hess. 364 pp., index. J. B. Lippincott Co., Philadelphia. For sale by the *Mining and Scientific Press*. Price \$5.

Though principally intended to aid the work of machine design in technical schools and colleges, this book should also prove decidedly useful in drawing rooms as a book of reference. The work is admirably illustrated with good line drawings and graphic tables, which are of great service for quick calculations. Chapter on hoisting machinery refers to that type of hoist required for crane and derrick service, rather than for larger hoisting engines, such as are used for mining. In the chapter on electric hoists no attempt has been made to go into details of design of the electrical apparatus itself, outside of a general discussion of the types of motors developed by manufacturers for this purpose and their application to various requirements for cranes and derrick hoists. As a whole, this work is excellent and will form a valuable addition to any technical library.

**COAL: ITS COMPOSITION, ANALYSIS, UTILIZATION, AND VALUATION.** By E. E. Somermeier. 175 pp., ill., index. McGraw-Hill Book Co., New York, 1912. For sale by the *Mining and Scientific Press*. Price \$2.

This little book has been written by the professor of metallurgy at the Ohio State University, in order to bring to mechanical and power plant engineers, chemical engineers and chemists, and laymen interested in purchase or sale of coal, the newer results on its sampling, analysis, and valuation. The subjects covered include the composition and heating value; chemical analysis; sampling; methods of analysis; determination of calorific value; summary of chemical determinations and records; coal washing; purchase of coal under specifications; fuel gas analysis; and analytical tables. Because of Mr. Somermeier's intimate connection with the testing work begun at St. Louis by the United States Geological Survey and continued by the Bureau of Mines, and his contact with teaching and commercial work, he is especially qualified to write such a book as this. He has succeeded admirably in condensing and clarifying the large amount of material available and has produced a readable book of wide usefulness.

**THE DESIGN OF STEEL MILL BUILDING.** By Milo S. Ketchum. 478 pp., index. McGraw-Hill Book Co., New York. For sale by the *Mining and Scientific Press*. Price \$4.

Mr. Ketchum's works covering the applications of steel structures have been recognized as standard for many years. The first edition was issued in 1903, and was so well received that a second edition was published in 1906. This is the third edition, which has been amplified and enlarged in order to bring the text up to improvements in practice that have taken place during the past six years. The chapters on 'Stresses in Framed Structures' and 'Stresses in

Bridge Trusses' have been rewritten and enlarged. Specifications for steel-frame buildings have been revised and rewritten. Many additions have been made, including two in graphic statics, and appendix III, covering structural drawings, estimates, and designs. The latter contains 78 pages, 30 tables, and 24 illustrations, which furnish much data not readily available. While the title would indicate that steel buildings monopolized the text, the greater part of the data given really applies to steel building design in general.

**A TEXT-BOOK OF PHYSICS.** By Wilmer Duff and others. 686 pp., index. P. Blakiston's Son & Co., Philadelphia. For sale by the *Mining and Scientific Press*. Price \$2.75.

The third edition of a well known book, the section devoted to 'Mechanics' has been prepared by A. Wilmer Duff; 'Wave Motion,' by E. Percival Lewis; 'Heat,' by Charles E. Mendenhall; 'Electricity and Magnetism,' by Albert P. Carman; 'Conductivity of Electricity through Gases and Radio-Activity,' by A. K. McClung; and 'Sound,' by William Halllock. The primary object in the preparation of this work was to provide a textbook for students that would present the laws of physics and the various phenomena pertaining thereto, clearly and concisely, in order that a thorough understanding of the fundamentals would be assured before proceeding with a study of their application. The various co-authors are all teachers of note, who have brought their experience to bear by the preparation of the text to suit the needs of students. While no essential feature has been overlooked in any of the sections into which the book is subdivided, there is an absence of the padding and verbosity that often characterize a work of this kind. It is a publication well worth while, not only for students in schools and colleges, but for older men engaged in engineering practice, who will appreciate the thoroughness and systematic grouping of the subject matter whenever there is occasion to indulge in a little 'brushing up.'

**AMERICAN CIVIL ENGINEERS' POCKETBOOK.** Second Edition. Edited by Mansfield Merriman. 1400 pp., index. John Wiley & Sons, New York. For sale by the *Mining and Scientific Press*. Price \$5.

This work needs no introduction to the engineering fraternity, as the first edition has won for itself a position in the reference libraries of civil engineers that has made it indispensable for the practice of this branch of the engineering profession. The first edition was issued in December 1910, and was so favorably received that a reprint was necessitated three months later. The second edition of 15,000 copies contained two new sections, namely, section 14, giving the elementary principles of steam and electric engineering, which are of special value to civil engineers; and section 15, setting forth the most recent practice regarding the construction and maintenance of highways and streets. Eight new pages are added in section 2 on earthwork computations. Section 3 has been given over entirely to steam and electric railroads and seven pages of additional matter. Many other changes have been made throughout the text, bringing the subject matter up to the minute as far as developments in practice are concerned. Nothing of importance contained in the first edition has been eliminated, and there is no doubt that the second edition of this work will maintain the prestige of its predecessor.

**HANDBUCH DER REGIONAL GEOLOGIE: UNITED STATES OF NORTH AMERICA.** By Eliot Blackwelder. 258 pp., ill., paper covers. Heidelberg, 1912. For sale by the *Mining and Scientific Press*. Price \$4.50.

This forms the second part of the eighth volume of the series of handbooks now being issued under the editorship of Messrs G. Steinmann and O. Wilkens. The books follow a general plan, and collectively will constitute an up-to-date encyclopedia of geology. Mr. Blackwelder's volume is an admirable discussion of the stratigraphy of the United States under the general headings: morphological summary; stratigraphy and formations; outline of geological history;

orographic elements; and economic geology. The value of the book lies in its freshness and the amount of new data included. The chapter on the orographic elements is especially good. On the other hand, that part which relates to economic geology is not as well done as is the rest of the book. In discussing copper, Bisbee, Butte, Lake Superior, and Ducktown are taken as the type deposits, and the account of Butte is based upon the U. S. Geological Survey Folio, later material being ignored. Condensed as the material relating to any one metal must be in such a work, a listing of typical deposits which omits the porphyry copper at Bingham, is glaringly incomplete. So, too, in discussion of gold. The rich deposit at Goldfield, Nevada, is exceptional rather than typical, and the statement that "the term 'orebodies' can hardly be applied fittingly to the Homestake deposits" is permissible only as rhetorical exaggeration. The book closes with a brief summary of the literature of the subject in which the principal sources of data are indicated.

## Recent Publications

The following advance chapters from the 'Mineral Resources of the United States, Calendar Year 1911,' U. S. Geol. Surv., Government Printing Office, Washington, D. C., 1912, have been received:

THE STONE INDUSTRY IN 1911. By E. F. Burchard. 96 pp., 7 plates.

THE PRODUCTION OF COAL IN 1911. By E. W. Parker. 207 pp., 2 text figures.

THE PRODUCTION OF LIME IN 1911. By E. F. Burchard. 76 pages.

THE PRODUCTION OF TUNGSTEN, VANADIUM, URANIUM, TITANIUM, MOLYBDENUM, NICKEL, COBALT, AND TANTALUM IN 1911. By F. L. Hess. 24 pages.

THE PRODUCTION OF NATURAL GAS IN 1911. Text by D. T. Day, statistics by B. Hill. 57 pp., 2 text figures.

THE PRODUCTION OF GLASS SAND, OTHER SAND, AND GRAVEL IN 1911. By E. F. Burchard. 56 pages.

THE PRODUCTION OF COPPER IN 1911. By B. S. Butler. 63 pages.

ZINC AND CADMIUM IN 1911 (SMELTER PRODUCTION). By C. E. Siebenthal. 54 pp., 4 text figures.

LEAD IN 1911 (SMELTER PRODUCTION). By C. E. Siebenthal. 41 pp., 4 text figures.

AN INVESTIGATION OF EXPLOSION-PROOF MOTORS. By H. H. Clark. Bulletin 46. 44 pp., 6 pl. Bureau of Mines, 1912.

IGNITION OF GAS BY STANDARD INCANDESCENT LAMPS. By H. H. Clark. Technical Paper 28. 4 pp. Bureau of Mines, 1912.

COMMISSION OF CONSERVATION, CANADA. REPORT OF THE THIRD ANNUAL MEETING. James White, secretary. 154 pp. John Lovell & Son, Ltd., Montreal, 1912.

RESULTS OF SPIRIT LEVELING IN OHIO, 1911. By R. B. Marshall. U. S. Geol. Surv. Bull. 518. 108 pp., 1 pl. Government Printing Office, Washington, D. C., 1912.

QUALITY OF THE WATER SUPPLY OF KANSAS. By E. H. S. Bailey. U. S. Geol. Surv. Water-Supply Paper 273. 375 pp. Government Printing Office, Washington, D. C., 1912.

METHODS FOR THE DETERMINATION OF WATER IN PETROLEUM AND ITS PRODUCTS. By I. C. Allen and W. A. Jacobs. Technical Paper 25. 13 pp. Bureau of Mines, 1912.

OIL AND GAS DEVELOPMENT IN NORTH-CENTRAL OKLAHOMA. By R. H. Wood. U. S. Geol. Surv. Bull. 531-B. 31 pp., 1 pl. Government Printing Office, Washington, D. C., 1912.

LIGNITE IN MONTANA. By W. R. Calvert, C. F. Brown, F. A. Herald, J. H. Hance, E. Stebinger, and A. L. Beekly. Advance chapter from Bulletin 471, 'Contributions to Economic Geology, 1910, Part II,' U. S. Geol. Surv. Bull. 471-D. 176 pp., ill., maps. Washington, 1912.

## Lunkenheimer 'Puddled' Semi-Steel Valves

The increasing use of high pressures and superheated steam has created a demand for something better than the ordinary cast iron brass mounted valves. To meet this demand, The Lunkenheimer Co., Cincinnati, Ohio, offer their line of 'puddled' semi-steel valves. 'Puddled' semi-steel is an extremely high-grade iron and steel alloy, of very close grain and strength. It must not be confused with the mixtures made in cupolas where the admixture of steel with the iron is beyond control, and the resulting metals sadly lacking in uniformity. Lunkenheimer 'puddled' semi-steel valves have been extensively used in high-pressure plants carrying superheated steam, and in other places where the physical demands on a valve are great, and in every case they have given complete satisfaction. These valves are made in two combinations as regards the material used for the trimmings, and are designated as combinations C and D. The object of these combinations is to suit various conditions of superheat and to meet the specifications of engineers who differ as to the metal that should be used in the trimmings. Combination C is guaranteed for 600°F. temperature, and combination D for 550°. Both combinations are suitable for 250 lb. pressure per square inch. The line includes globe, angle, cross, check, gate, non-return safety boiler stop-valves, etc. For extreme conditions of pressure, superheat, and strain, The Lunkenheimer Co. manufacture the above line made of cast steel, the tensile strength of which is about 80,000 lb. per square inch. For lower pressures and temperatures, the line is made of a high-grade cast iron.

A full description of these valves, together with that of the complete line of high-grade engineering specialties made by The Lunkenheimer Co. can be obtained by referring to their 654-page catalogue, 1912 edition, a copy of which the company will send upon request.

## Catalogues Received

DENVER QUARTZ MILL & CRUSHER CO., Denver, Colorado. Catalogue No. 10. 26 pages. Illustrated. 9 by 6 inches.

GEO. W. MYERS, Kohl building, San Francisco. Pamphlet on 'Ideal' Battery Stamp Stem Guide. Illustrated. 3½ by 6 inches.

WESTERN GAS ENGINE CO., Los Angeles, California. Catalogue F, 'Western Gas Engines.' 64 pages. Illustrated. 9 by 6 inches.

DELAVAL STEAM TURBINE CO., Trenton, New Jersey. Catalogue on Class 'C' Turbines. 47 pages. Illustrated. 3½ by 6 inches.

E. J. LONGYEAR CO., Minneapolis, Minnesota. Catalogue and price list of diamond-drills and supplies. 64 pages. Illustrated. 3½ by 6½ inches.

EDGAR ALLEN AMERICAN MANGANESE STEEL CO., Chicago. Bulletin No. 52, 'The Komata Liner for Tube Mills.' 20 pages. Illustrated. 6 by 9 inches.

UNITED STATES ENGINEERING CO., 80 Wall street, New York. Brochure B. M. 1, 'Briquetting Machinery.' 16 pages. Illustrated. 7 by 10 inches.

THE parts that get the greatest wear in a rock-drill are the cylinder, chest, and air-head. In the common run of drills, in which these parts are made of gray iron castings, a constant source of trouble and expense is found. This weakness has been entirely overcome in the WOOD ROCK-DRILLS by the substitution of vanadium tungsten iron for gray iron in the castings for these parts. Broadly, the vanadium iron in Wood drills gives about 200% more wear than the cast iron commonly used, besides being almost unbreakable. The superior economic value of this construction makes the Wood drill worthy of investigation by all interested in rock-drilling.

## EDITORIAL

CONGRESS is in session again, but matters held over from the spring term are likely to engross the attention of both Houses.

ANNOUNCEMENT that the Wall rolls have been discarded at the mill of the Ohio Copper Company presumably presages the appearance of interesting reading concerning the personnel and activities of the company.

NICARAGUA is chiefly associated in the popular mind with revolutions, but it is productive of much more of benefit. The description of the Chontales district, which we present this week, is of interest and value, both because the western part of Nicaragua is less well known than the eastern, and also because it is written by a well informed engineer who has devoted much study to the district.

SUGGESTIONS as to the exhibit which the mining industry may properly be expected to make at the exposition in San Francisco in 1915 are elsewhere advanced by Mr. Harold French. There is need for urging coöperation, for the work of preparation of a creditable exhibit will be great, but it is only just to add in this connection that apparently the exposition officials stand in need of urging quite as much as the mining men. Though official announcements of the advanced state of preparations are frequently made, it is nevertheless true that the name of the director of the mining exhibit has not been announced, and outside organizations receive little of definite information in response to inquiries as to what should be done in preparing for 1915. More activity is needed inside as well as outside the exposition organization.

SUPPLEMENTING the review of the Eastern metal market, given elsewhere, it is interesting to note that while the copper market has been more or less directly affected by the Balkan war, as has that of tin, though to a lesser extent, other minerals which are important but not so conspicuous in American manufacturing have also been affected, and in some cases seriously. Aside from heavy consumption, high ocean freights imposed because of the war are in part responsible for the advances in the price of ferromanganese, the higher rates even applying to the poorer grades of ore which are exported from Brazil. Ferromanganese is now strong at \$75 for spot delivery, \$65 and upward for first half, and \$61 for last half. Chromite, essential to the steel industry, and of which Turkey and Greece are the principal sources of supply, is higher in price, not alone from the increased demand due to the greater activity everywhere in the making of steel, but because of the desertion of the mines by laborers who have gone to join their national armies. Quotations for Greek and Turkish chromite, which averages 40 to 45 per cent in chromic oxide, vary from \$13 to \$15 per ton of 2000 pounds at the seaboard, according to the size of the lots. Magnesite, of which Austria is the chief source of supply, though California is an important producer, is also affected, but not so seriously, by the troubles in the southeast of Europe.

## The Mining Congress at Spokane

Spokane members of the American Mining Congress may well feel satisfied as they recall the sessions held in their city last week. While the number attending was not so large, nor were the names of the speakers so well known as at the Chicago convention of a few years ago, the meeting was not less interesting and will perhaps prove equally influential. In two particulars the Congress achieved the unusual—the sessions were devoted to real and informing debate, and the local committee must dispose of a surplus before disbanding. The first was in part the fortunate result of chance; the second followed careful planning and brilliant executive work. The preliminary program carried the usual list of distinguished names. Governors, senators, judges, and lawyers, with an occasional mining man, were to have delivered addresses on various phases of the relations of mining to public policy. Practically all these distinguished gentlemen found it inconvenient to attend, and most of them failed even to send papers to be read in their absence. One of the exceptions among the latter was Mr. Henry S. Graves, the United States Forester, who contributed a paper that provoked one of the liveliest discussions of the week, one that at times verged upon acrimony. It is to be regretted greatly that this debate was closed, though without any such plan on the part of the officers of the Congress, without allowing the representative of the Forest Service an opportunity to reply to the various charges and criticisms made on the floor. Most of these were trivial and could doubtless have been easily explained, while such a reply would have necessarily brought into sharper relief the real causes of friction. Those present at the Goldfield meeting of the Congress will recall the fairness with which criticisms of the Forest Service were met by its representative, and substantial good in several particulars followed. Unfortunately, the Spokane meeting, in this particular, seems likely to lead to increased friction rather than to agreement. In the main, however, the discussions were good-tempered and will prove helpful. If occasionally a speaker shot beyond the mark it was doubtless only the unthinking result of active discussion of what to the speaker appeared to be great wrongs. Remembering the point of view of the speakers, the general repression was admirable.

Discussion crystallized mainly around three topics: (1) protection of the mine investor; (2) Alaskan problems and conservation; (3) workingmen's compensation. Remembering the days when the Mining Congress consisted almost wholly of promoters and peddlers of worthless stock, something of the progress of the organization became apparent to one listening to the debate on the first topic. It was generally agreed that the mining industry suffered from the sale of worthless stock. The old slogan, 'outside money keeps the camp alive,' was not once sounded, and the need of real protection was urged from all sides. To the proposal that each state practically censor all stock sold within its borders and pass on the value of the property, the objection was urged merely that it was impractical. The consensus of opinion seemed to be that the state should provide the fullest measure of publicity, with suitable penalties for misstatements, rather than approve or disapprove each proposed issue. This plan will give every investor the means of protecting himself. This, we think, is a sensible conclusion. As a first means of attaining this end, the Congress provided a committee to compile and publish existing laws and compare their efficiency.

Alaskan problems, with which were entangled the leading phases of conservation, and the need of revision of the mining laws, formed easily the main topic of interest for the Congress. The delegates were fortunate in having

on the platform Mr. Falcon Joslin, and on the resolutions committee Messrs. John M. Steele and M. D. Leehey, whose knowledge of Alaska is at once comprehensive and obtained at first hand. Others contributed to the discussion, but Mr. Joslin, by his clear and forceful presentation of conditions met at Washington by the Alaskan committee of the Congress, made possible practical agreement upon an effective program. Briefly, the Congress approved unanimously of the work already done by its committee, and instructed it to work for the building of railway lines, either through government aid or at government expense, and the opening of the coalfields upon the most favorable leasing system to which consent of Eastern senators and congressmen can be secured. In the matter of proposed changes in the general mining law, the Congress endorsed fully the position taken by Mr. E. B. Kirby and his associates, published in full in the *Mining and Scientific Press* last week, and urged the appointment of a congressional commission to hold hearings preparatory to a general revision of the mining statutes.

The third topic actively discussed on the floor was workingmen's compensation. When account is taken of the fact that the Congress is mainly made up and supported by operators, our labor friends may well take pleasure in the fact that the principle of workingmen's compensation was unequivocally endorsed. Defects in existing compensation acts were cited and injustices on both sides were illustrated, but to the fundamental doctrine that each industry should bear its own burdens and that it is better to pay the workman than the claim agent and the lawyer, there was no dissent. In this, as in other matters, the American Mining Congress is reflecting the best sentiment among mining men and keeping a little ahead rather than behind; which is exactly where such an organization should stand.

The entertainments offered to the visiting members and delegates were numerous and excellent. At clubs, theatres, mines, and mills, all doors were open. The excursion to the Coeur d'Alene was well arranged and excellently conducted, and allowed the visitors to get at least a general notion of the scale of the work and the methods employed in that great district. The most enjoyed entertainment was the 'Spokane Diggins,' an old-time mining camp extemporized in a large skating rink. Here 'Brunton's livery stable' fronted the general store, where one could, according to the signs, buy "suits, sardines, shoes, suspenders, and notarie public," while just around the corner 'Big Bertha's' dance hall did a flourishing business, and at 'Dutch Jake's Club' one might bet recklessly on faro or roulette with the 'phony' money liberally supplied to delegates. Amateur boxing matches and vaudeville entertained the street crowds. 'Galena Alley,' a realistic picture of one phase of early mining conditions, had been "closed by the sheriff," and through the whole camp there was excellent order. In the closing hours of the last night one of the dancers, unfortunately, performed as in a modern city slum, and so smirched an excellent and appropriate entertainment. It is but fair to say that this feature was not on the program, and that the chairman of the local committee promptly started a policeman to stop the performance. On the whole, 'Spokane Diggins' was a harmless, instructive exhibition that emphasized progress rather than stimulated retrogression. This session of the Congress must be adjudged to have proved distinctly helpful. Doubtless its influence will be felt widely in the framing of the new legislation that the times demand. Election of Mr. D. W. Brunton as president for the next year, and selection of Mr. Heanen Jennings as vice-president, emphasizes the position the Congress is acquiring among men of rank in mining. The membership is changing and the work of the organization must change also. The new board of directors

will face grave problems of organization and finance, but with the prestige of genuine success and with the cheerful optimism that goes with mining, they should be able to direct the American Mining Congress into fields of even greater usefulness.

### Local Sections of the Institute

Not the least among the important provisions of the revised constitution of the American Institute of Mining Engineers, which we published in full last week, is the by-law providing for the organization of local sections of the Institute, and it may eventually prove one of the most vital. The discussion of Institute affairs during the past year has unimpeachably demonstrated that one of the critical problems of the society is the awakening and maintaining of the interest of the membership at large.

Of the desirability of the organization of local sections there can be little question. To doubt whether the Institute will benefit from their activities is equivalent to urging that a large business firm derives no benefit from the work of branch agencies. In this case the probable benefit is even less in doubt. The securing of desirable new members can be done much more effectively by local groups of members than through the secretary's office, as well as the stimulation of contributions of original papers and discussion, now that the organization has grown to a membership too great for even a committee to know all those who might contribute valuable papers to the *Transactions*. Effective service may be done in many other ways, and the aim should be to encourage organization in such a way as to most effectively secure the maximum of this. The problem may be approached from the viewpoint of securing the maximum of benefit to local members, regardless of its effect on the Institute as a whole, of limiting the sections so rigidly to prevent any possible local action inimical to the interests of the whole society, or of securing the greatest good to the greatest number. It will scarcely be urged that local sections should be allowed *carte blanche* in their activities, since embarrassing complications might thus arise. But to our mind, this fear is an exaggerated one, resembling the gloomy prophecies of speedy disaster when the referendum and recall were enacted in some Western states. Experience has gone to show that the general public exhibits a level of intelligence comparable, at least, to that of its representatives, and in this case it is probably not rash to assume that local members will comport themselves as becomes intelligent men. On the other hand, it must not be overlooked that the organization of a section in any mining centre is an individual problem. In one place, for example, there may be in existence a flourishing social organization of engineers, so that the section must be restricted to technical matters, while in another technical matters can best be coordinated with social activities, to the benefit of both. The work of any given section will, therefore, be largely shaped by the local conditions. Too strict control of branches by the head office leads to a good deal of friction in the business world, and in this case is likely to operate to hinder the organization and maintenance of sections.

Passing from the general to the specific, we believe that two provisions of By-law XVIII need revision before adoption. For the Institute to contribute from its funds for the support of local sections, leaving the latter without means to secure funds except through appeal to the Board of Directors, is at once an artificial and presumably unworkable arrangement. An organization without the power to raise funds is a helpless one, and it is at least doubtful if success is possible under any such arrangement. The permission to solicit voluntary contributions for the purpose is undesirable, and would transform the local secretary into a pro-

fessional mendicant, making his ordinarily arduous and vicarious labors still more unacceptable. The success of any section will largely depend upon its secretary, and his work should be aided, not hindered. If the local section at Douglas, Arizona, for example, should find it feasible to organize as an ordinary club and wish to assess the club members at the rate of \$2 per month, it should be possible for them to do so, and both the Institute and the local members will be the gainer thereby. Common sense and business experience indicate that all members of the Institute resident in the territory of a section should be free to join it when first formed, or at the time of their election, and if they fail to avail themselves of the privilege may only do so later under such restrictions as the section may impose. The funds required by a section should be raised by the members of a section, who will automatically regulate their needs by what they are willing to subscribe. Adjustment of the territory of a section by the Board of Directors is unobjectionable if exercised with discretion. But in the case of the Mining and Metallurgical Society the members in western Nevada are grouped with those of Utah, though for geographical and business reasons they rarely visit Salt Lake City, and are constantly in San Francisco. The needs and convenience of the local members should at least influence the actions of the central governing body.

The provisions in regard to papers presented before local sections are of even greater importance. In this regard also the sections should be largely autonomous, and the provisions of the by-law seem to us based upon a misconception of the proper field of the Institute as a publishing medium. To the transactions of a learned society there should attach a prestige which no other medium of publication possesses. Papers there printed are published simply because they are of permanent value. The technical journals print articles which are primarily interesting and often only of temporary value. If they are also of permanent value, so much the better. A journal must be interesting, otherwise it will fail; the *Bulletin* need not be interesting, for if it contains papers of permanent value the members will preserve it and read it, even though unable to stifle yawns in the process. In other words, the factor of value is the primal one in the publications of a learned society, the factor of interest is fundamental in a journal. On the other hand, interest is essential in a local section. For that reason many of the papers there presented will be unsuitable for publication in the *Transactions*, and the requirement of submission of manuscript may often tend to prevent the presentation of interesting informal accounts of matters which members are willing to talk about, but unwilling to put in print in unalterable form. Engineers when urged to write accounts of work which has been carried on under their direction frequently reply that the experiments were discontinued when the immediate results required were obtained, the investigation was never completed, and the experimenter is unwilling to publish uncompleted work. Large companies frequently discourage publication of articles by their employees, and a local section at Butte, for example, would find the greatest difficulty in securing papers for publication in the *Transactions*, while matter for oral presentation only might be freely offered. In this respect as well the sections should be autonomous. Matter which is sufficiently valuable for publication in the *Transactions* will be held for that purpose by the author (previous publication, of course, invalidating any claim to that privilege), and papers of less interest should be left to the discretion of the local secretary. The work of creating and maintaining interest in a local section will devolve upon its members, and it is not unreasonable to suppose that they may properly serve as the best judges of what is possible and desirable under the conditions which must govern them.

# The Chontales Mining District, Nicaragua

By ARTHUR FEUST

The Chontales district lies on the western side of the Republic of Nicaragua, about 42 miles by road slightly north of east from the port of San Ubaldo, which lies on the northeast shore of Lake Nicaragua. This distance is from San Ubaldo to La Libertad, which is the focus of the western end of the district. The eastern end centres in Santo Domingo, 10 miles east of La Libertad.

## EARLY HISTORY

The district was discovered in the early sixties, the San Juan mine, close to La Libertad, being the first located.

Chamarro, 3 stamps; Los Angeles, 4 stamps; Santa Fe, 3 stamps; and Virginia, 3 stamps. The production of the district is between \$15,000 and \$20,000 per month (mostly from the first five named), which, considering the light stamps (750 lb.), that few are cyaniding even the sand, and none treating slime, and all depending on the available water-power at or close to the mine, is rather a fair showing. This production will be somewhat augmented during 1913 with the erection of four more leaching plants and the first slime plant in the district, at the Babilonia mine.

It was closely followed by discoveries at Santo Domingo, where Thomas Belt, the famous English naturalist, was manager of the Chontales Mining Co. from 1864 to 1868. After meeting with varied success, most of the companies that depended entirely on amalgamation abandoned their properties, and the district was practically deserted until some six years ago, when the cyanide (leaching only) process was first introduced. This, together with the purchase of the Babilonia mine by Bewick, Moreing & Co., started the present revival.

## PRESENT STATUS

At the present time there are eleven producing properties in the district, of which the Babilonia mine, of the Babilonia Gold Mines, Ltd. (Bewick, Moreing & Co.), with its pneumatic stamp of some 35 tons capacity and leaching plant probably holds first place, closely followed, if not surpassed, by the production of the 5-stamp mill of the Cedro mine, without a leaching plant, now being installed.

Following comes the Javali with 19 stamps (10 single cam) and leaching plant; Esmeralda, 15 stamps and leaching plant; Pavon, 1 Husband pneumatic stamp; Costa Rica, 8 stamps; San Juan, 9 stamps; Carmen, 6 stamps;

## GENERAL GEOLOGICAL FEATURES

The geological formation of the Chontales district is everywhere eruptive. Andesites, probably augite andesite (?) predominate, with intrusions of greenstone roughly paralleling the general trend of the veins. The mineralized area consists of a series of roughly parallel fissure veins with a strike varying from N.45°E. at the La Libertad end to N.70°E. at the Santo Domingo termination, dipping in places to the north and in others to the south, but with very slight variation from the vertical plane. There seem to be two principal vein systems; one on the northern and the other on the southern boundary, some two miles apart and 15 miles in length, the area between being occupied by smaller veins which in some cases are approximately parallel to the strike of the larger ones, but which may later prove to be ramifications or branches of these.

The larger veins are generally looked upon as continuous, consisting of lenses of quartz (varying in width from a few inches to 32 ft.) which peter out into stringers or hilos of varying size for a distance and then unite again, forming other lenses. These lenses vary from 50 to 500

ft. or more in length, some consisting entirely of vein matter, while others carry horses of country rock of varying width and length which in some cases are sufficiently wide so as to form three or more distinct orebodies.

The veins at the western end of the district are oxidized to a greater depth than at the eastern end, with one exception, the San Juan mine. The vein matter generally is softer in the mines on the western end and car-

ous angles to the plane of the strike in the orebodies proper, which vary from the width of a knife-blade to 1 in. thick, and which seem to bear some intimate relation to the mineralization of the veins, as there is a considerable rise or fall in the gold content after passing through one of these, besides a distinct change in the character of the mineralization, one side being stained with oxides of iron and the other with manganese. These

INTERIOR OF JAVALI MILL.

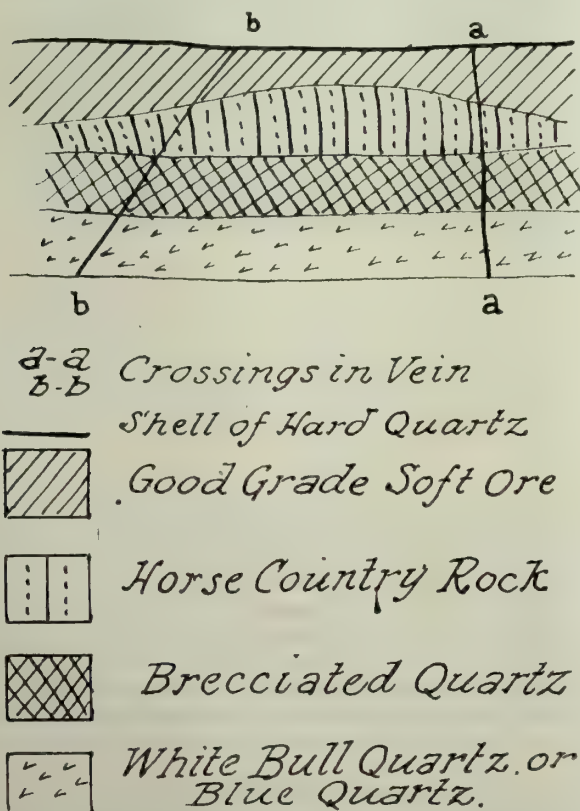

JAVALI CYANIDE PLANT.

ries less silver than at the eastern end. These facts, coupled with surface observations on the depth of overburden, incline me to the idea advanced by Oscar Hershey<sup>1</sup> concerning the Pis Pis district, that the zone of oxidation, which is irregular and indistinct, depends to a

crossings contain principally manganese in the form of pyrolusite, with some quartz, and occur at intervals of 10 ft. or more. They resemble the crossings described by R. Gilman Brown at the Standard Consolidated, Bodie, California, some years ago. See the accompanying sketch showing a horizontal section in the Esmeralda mine.

The vein matter consists of quartz of three distinct types; white 'bull' quartz, at times jasper, nearly always barren or practically so, giving way at times to a dense hard blue quartz which is well mineralized, usually containing the original sulphides; brecciated quartz carrying some valuable mineral; and the more friable, sugary, and ribbon-like quartz which forms the bulk of the ore. Vugs of

HORIZONTAL SECTION, ESMERALDA MINE.

great extent on the thickness of *manta* or overburden, which is practically impervious to atmospheric agencies, and also on the texture of the vein matter at any particular place, as in some instances sulphides have been observed in compact quartz in the outcroppings.

Besides these, other characteristics are crossings at vari-

VERTICAL VEIN SECTION, COSTA RICA.

drusy quartz are found in all except the brecciated quartz, but more frequently in the white bull quartz.

From my observations and assays I am of the opinion that the amount of gold and silver found in the present sulphide areas above the water-level, which is somewhat lower than that in the oxidized areas, indicates to a certain extent the content one may expect to find in depth. These sulphides consist of pyrite with smaller quantities

<sup>1</sup>Mining and Scientific Press, February 17, 1912.

of argentite, galena, and sphalerite, and occasionally chalcopyrite and arsenopyrite. The difference in content I expect to be small, as the walls close to the surface are badly decomposed, diluting the ore, but in depth become harder, allowing a cleaner product to be mined.

#### METHOD OF DEVELOPMENT AND MINING

All the mines in the district are developed by adits at intervals of 20 to 90 ft. vertically. These are connected by raises at intervals of 20 to 100 ft. or more. With the exception of the Babilonia, Javali, and Costa Rica, no systematic development has been attempted. The smaller owners 'gopher' out the ore as fast as they find it, without any attempt at systematic stoping, usually by driving wide levels with a 10-ft. pillar between, and still they politely inform you they are developing, not stoping.

Where stoping is done, the stopes are filled with waste run in from the surface, as walls in the superficial workings crumble and slab off on short exposure. A notable feature in the entire district is the absence of waste dumps of any size, such as are seen being very small in proportion to the work done. The only sinking so far attempted in the district is at the Babilonia mine, where the shaft is now down over 100 feet.

#### TREATMENT OF ORE

On account of the sticky condition of the superficial ores (in the rainy season) nearly all the mines use the slope of a hill as an ore-bin, from which the biggest pieces are sorted and broken by hand or passed through one of various types of jaw crushers, then fed by hand to either gravity or pneumatic stamps, no automatic feeders being used in the entire district. Some mines follow this with arrastres, as these in regrinding save some of the finer gold.

The sand from the plate is collected either in a box from which it is shoveled out, or else run to a pond in which it collects, together with considerable slime. The Javali mine is the only one using a classifier at present. But I found no difficulty in treating sand from well oxidized ore containing 15% -150 mesh (the finest screen available) as long as it was uniformly distributed, but in several cases of poor extraction the slime which caused the trouble was in lumps, producing layers. This trouble was overcome by stationing a boy in the tank while charging same to break these up with a shovel. In treating some 6000 tons of old tailing I obtained an extraction of 88.6% gold, excluding the first month's run on a product which was very irregular. The supplies and quantities consumed per ton were as follows. Cyanide in terms of KCN, 0.639 lb., using both sodium and potassium cyanide; lime, 4.765 lb. (various grades of lime); zinc, 0.277 lb. per ton. The cost per ton, including labor, superintendence, and supplies, was \$0.98. The bullion was 750 to 800 fine. The treatment consisted of a 5-day leach with solutions containing 2 lb. and 5 lb. of KCN in terms of free cyanide. The solution contained not over 0.15 lb. protective alkali in terms of NaOH.

#### SLIME

The slime, which forms 40 to 60% of the product (on the superficial ores), is run to waste except at the Babilonia mine, where it is impounded. But the slime presents no serious difficulties and could be readily treated by any of the various types of agitators and vacuum-filters. When the sulphide problem is approached, which in some cases is close at hand, I believe that concentration and sliming, possibly only sliming, will be the treatment adopted.

#### LABOR

As a laborer the Nicaraguan is inferior to the Mexican, both as a miner and surface worker. There is likewise a vast difference between the Atlantic and Pacific sides of Nicaragua with regard to the question of labor. To begin with, on the Atlantic side the labor consists of Jamaican negroes, Nicaraguans, and Indians, with a large proportion of the former, while on the Pacific side labor is scarcer and operators are dependent on Nicaraguans and

Indians, chiefly the former. Secondly, on the Atlantic side the currency is silver, which does not fluctuate so violently as the paper currency on the Pacific side.

Labor is the critical issue that the mine-owners and operators at Chontales have to face at the present day, for with a poor crop the past year and the unstable monetary and political conditions there are violent fluctuations in the cost of foodstuffs, and in consequence the miners at times barely earn enough to live on. Wages are at present 5 to 8 pesos per day, with board at 5 pesos per day. At the average exchange, 16 pesos equal \$1. To raise the wage scale is suicidal, as the exchange may fall at any time (once the pending loans are arranged), so there is but one alternative, now adopted by the largest operators: to sell foodstuffs at a loss in order to have a plentiful supply of labor until the financial conditions become settled. It is one thing to raise the wage scale, but a rather serious one to reduce it, as the average laborer has no conception of the value of the *billette* and none whatever of exchange rates.

The laborer or the native miner is the keenest 'high-grader' or *güiris* that I have seen. Samples of stolen ore showed as low as \$50 per ton in one instance, and the assayer at one mine informs me that he has assayed the so-called rich streak where they noted 'high-grading' and found it to run only \$25 per ton. The low wage scale necessarily permits their working such a grade of ore at a profit to themselves.

#### TRANSPORTATION

All the freight consigned to the district enters the ports of Corinto or San Juan del Sur; from the former it goes by rail to Granada, and from the latter by carts to San Jorge, both ports on Lake Nicaragua. From Granada and San Juan del Sur by tri-monthly lake steamer service or schooners to San Ubaldo. In the dry season most of the mines get in their heavy freight, or what they can, as the season is short. Freight from San Ubaldo to the mines is done by contractors using bull-carts and pack-mules.

However, once the rains set in, the roads (if such one may call them) become quagmires, and carting becomes difficult; so heavy machinery has to be left until the dry season sets in again. In the rainy season oxen work to better advantage as pack-animals across the plains than mules, for although slower they plow through the mud much better.

Freight rates are at present 30 pesos to La Libertad per *carga* of 200 lb.; from there to Santo Domingo, 25 pesos, and, per additional league, 5 pesos added. This big difference in freight rates from La Libertad on reflects the condition of the road and trails, as from San Ubaldo to Santo Domingo is 42 miles and from the former to La Libertad 10 miles.

#### TIMBER AND FUEL

Although not in superabundance, there is a fair supply of timber for mining and structural purposes. For mine timbers the following are the principal ones used: *nispero* (medlar-tree), *palo de piedra*, *nauzite*, and *barazón*; for structural work, *cedro marchó* and *cedro real* (cedar), *bimbajan*, *areno amarillo*, and *caoba* (mahogany); the first three being superior, as they are not attacked by wood ants; for fuel, *roble* (scrub-oak), *canelo* (cinnamon tree), *guavo*, and *manga larga blanca*; whereas for making charcoal, *nispero* (medlar), *cortez*, and *barazón* are superior.

#### POWER

With the heavy rainfall one would think there was an abundance of water-power available, but such is not the case, and good power sites close to the mines, except at Javali and Pavon, are scarce and hard to develop, and even these are liable to run short in the dry season. Wood as fuel soon becomes costly and is not used, so that in the near future hydro-electric power from the Atlantic side, or its tributaries, or some of the various types of gas or oil engines will have to be used, depending on the scale of operations and capital available. At present Pelton wheels are used everywhere.

# Large Synchronous Motors for Compressor Service

By GIRARD B. ROSENBLATT

The use of compressed air for certain classes of mining operations has been standard practice for a long time. The application of electric power for driving the compressors which furnish the air is also by no means new. It is, however, only within recent years that the advantage of building central air-compressor stations has received any great amount of attention from mine operators.

For large individual or separately owned neighboring properties, there are many advantages to be obtained from a centralized air-compressor station, some of the most obvious of which are the use of large units with consequent increased efficiency, reduced cost per horse-power installed, minimized cost of attendance and installation, and decreased cost of spare units. Other advantages not so pat-

attention from mine operators that it deserves. While direct connection necessitates a large slow-speed motor with very definite starting characteristics, it will usually be found, when viewing the matter impartially, that for units requiring motors of 350 hp. or larger, direct connection of the motor to the compressor-shaft will prove most economical. The economy may not be apparent in the first cost of the apparatus, but when the cost of foundations and buildings is estimated, when the increased efficiency due to the elimination of the belt or rope is ascertained, and when attendance is considered, it will usually be found that direct connection is best for units of moderate and large size.

The next point to consider is the type of motor to be

1200-HP. WESTINGHOUSE SYNCHRONOUS MOTORS, DIRECT CONNECTED TO AIR-COMPRESSORS, ANACONDA C. M. CO.

ent are the possible improvement in the load-factor and the use of a special form of electric drive, both of which tend to reduce the first cost of the installation and the cost of power operation. There are, however, many cases where the installation of a central compressor plant is not justifiable. Electricity usually can be transmitted to better advantage than can compressed air, which is markedly affected by temperature. The problem as to whether a centralized air-compressor plant will prove economical is one that must be decided for each particular case, but it will be found that the economy of centralized air-compressing machinery can often be proved for cases where the advantages are not so apparent on casual inspection. As the policy of centralizing air-compressor stations in mining is one worthy of considerable attention, a few words regarding the selection of electrical apparatus for such stations and a description of one of the largest stations in this country may be of interest.

Air-compressors for the pressure used in mining work (varying from 60 to 100 lb.) are usually reciprocating in type, and compound. They may be driven either by direct-current, induction, or synchronous motors. The motors may be connected to the compressors either by gear, belt, or rope drive, or mounted directly on the compressor-shaft. The use of a gear drive for large units is at present not recommended, except for exceptional cases. Probably for units requiring up to 500 hp., belt driving is at present the most popular, and for larger units rope driving has many adherents. The use of direct-connected engine-type motors has, for some unexplained reason, not received the

used. Except in coal-mining and similar plants, where much direct current is used, the source of available power is almost entirely three-phase alternating current at either 25 or 60 cycles; more generally at 60 cycles. Either induction motors or synchronous motors may be selected to drive the compressors. Both types offer advantages, but the advantages of the synchronous motor are not generally realized. In fact, until recently, the synchronous motor for mining installations has been regarded as something to be avoided. The fact that synchronous motors can be designed with reasonable self-starting characteristics is not generally known, and the fact that a synchronous motor can be designed which will have great stability and will not easily fall out of step is not realized by the many engineers engaged in the mining industry.

The direct-connected induction motor in the sizes under consideration is almost invariably of the wound rotor type with slip-rings to permit insertion of resistance in the secondary circuit during starting. The direct-connected synchronous motor for the same conditions is usually of the revolving field type, provided with a cage winding of the fields, at least to prevent 'hunting', if not to give self-starting characteristics. For either type of motor the speed to meet efficient commercial designs of compressors will vary from approximately 200 to 75 r.p.m. The starting torque required will range from 25 to 40% of full-load torque. Constant speed over wide ranges of load, or rather the maintenance of normal speed under heavy load, is to be desired.

For such service the two types of motors compare as

follows. The induction motor has the distinct advantage that no direct current is required for excitation. It will also exhibit somewhat better starting characteristics in that it will develop the required starting torque with a less draft of current from the supply-lines and develop sufficient starting torque even under conditions of low voltage. On the other hand, the synchronous motor can be designed to develop sufficient starting torque for any ordinary compressor, and will have a better efficiency than the corresponding induction motor. The induction motor will probably have a power-factor between 85 and 90% lagging at full load, while the power-factor of the synchronous machine will be unity, or the current may be leading and thus help to improve the power-factor on the system to which it is connected. While power is charged for on a kilovolt-ampere instead of a kilowatt or horse-power basis, this will mean a marked saving in the cost of power for the synchronous motor.

The induction motor will not be simpler than the synchronous motor. The stator windings on both machines will be of the same approximate type. The phase-wound rotor of the induction motor will be not quite as simple and rugged as the revolving field of the synchronous motor. Both machines will have collector-rings; the induction motor three, the synchronous motor only two. The starting device for the synchronous motor will be no more elaborate or complicated than that of the induction motor, and the air gap on the synchronous motor will be decidedly larger than that of the induction motor, a marked point in its favor. The synchronous motor will maintain a constant speed under all conditions of load. The induction motor on the other hand, will show a falling off in speed practically proportional to the increase in load up to full load, and a somewhat greater falling off in speed above full load. Both motors can be built for a maximum torque which will be well beyond the greatest requirements for the service, and the synchronous motor may be given characteristics that will insure its stability or power to 'hang on to the line' under abnormal conditions. These two facts are not generally realized by operators. Figures confirming this are given below.

In a plant having several units, the disadvantages of having an exciter for the synchronous motors is not so marked as where a single unit is installed, as one exciter may be employed to furnish direct current for a considerable number of synchronous motors. The starting of either type of machine is equally simple. In either case the compressor is 'unloaded' before starting. A self-starting synchronous motor synchronizes itself. If, as is the case in some plants, the synchronous motor is not self-starting, but is brought up to speed by the compressor, with its valves reversed, acting as an air engine, or by an auxiliary starting motor, special attention to synchronizing may still be avoided by the use of an automatic synchronizer.

The selection of a proper synchronous motor is not as easy as that of an induction motor. Any induction motor of the proper real capacity, voltage, frequency, and speed, with a reasonable pull-out torque, to carry it through periods of low voltage, and ordinary starting characteristics, will operate a compressor successfully, though possibly not as satisfactorily as might be the case with a more carefully designed machine. In selecting a synchronous motor for the same service, a number of features must be borne in mind which do not enter into the selection of an induction motor.

The first is the fact that development of the 30% full-load torque usually required at starting necessitates a power supply of from one and one-half to three times normal full-load kilovolt-amperes. A self-starting synchronous motor starts as an induction motor, and at that speed where it changes in action from an induction motor to a synchronous motor the torque suddenly falls to one-half or less of the starting value. The value of torque at this point is called the pull-in torque. The greatest torque is required at starting to bring the parts of the compressor from rest to motion. Thereafter less torque is required to speed them

up, but this torque must not be greater than what is termed the pull-in torque. Many synchronous motor applications have been unsatisfactory through overlooking this fact. The starting torque of a self-starting induction motor may be increased by increasing the resistance of the cage winding, but as this increase in resistance increases the slip of the motor operating as an induction motor, it increases the gap between the maximum speed the motor will attain under load when operating as an induction motor and its synchronous speed, which is its normal speed when operating as a synchronous motor, and the pull-in torque decreases as a result. In a well designed motor the resistance is so proportioned that a good balance between starting and pull-in torque is obtained.

The second feature is the fact that a certain amount of care must be employed in the selection of a proper fly-wheel for use on a compressor to which a synchronous motor is to be direct-connected. The compressor, being a piece of reciprocating machinery driven from a rotating machine, must have a fly-wheel to equalize the uneven efforts required to keep the reciprocating parts in proper motion. In other words, the fly-wheel stores energy through part of each revolution and returns it to the reciprocating parts at other portions of the revolution. The fly-wheel accordingly must generate impulses. In a simple compressor there would be two impulses per revolution; in a compound compressor, four. These impulses will give the fly-wheel a certain period of oscillation, depending on the amount of the impulses and the weight and radius of gyration of the fly-wheel. Care must be taken that this period of oscillation of the fly-wheel does not coincide too closely with the natural period of oscillation of the motor and the electrical circuit to which it is connected. The feature is not one that requires the attention of the user of the compressor, but to insure satisfaction to himself he should make certain that the matter has been given attention by the manufacturer of the compressor motor. For a given combination of synchronous motor and compressor there will usually be a considerable number of fly-wheels, differing in weight and diameter, whose period of oscillation will be absolutely safe. Some may be too light for the mechanical requirements of the compressors. Others may be so heavy that their cost will be inordinately high, but there will always remain a considerable number of reasonable dimensions from which a final selection may be made. As an appendix to this discussion, a brief outline of what has been done in practice may be of interest.

The Anaconda Copper Mining Co., at Butte, Montana, is pursuing the policy of centralizing its air-compressors. Four such central compressor plants have been placed in operation and marked economies obtained by so doing. In the three older plants induction motors with rope drives have been used. The total installed capacity varies from 1700 to 2400 hp. per plant, and the units range in size from 300 to 800 hp. For the most modern plant, direct-connected synchronous motors were decided upon after careful consideration and the size of individual units increased to 1200 hp. Three of the units have now been in successful operation for more than a year. A fourth unit is being installed and two more are to follow, making the ultimate total installed horse-power in this one plant 7200 hp., capable of compressing 45,000 cu. ft. of air per minute to 90 lb. pressure.

Apart from the size of the units and the use of direct-connected synchronous motors, this plant is unique in refinements that have been incorporated to maintain a high efficiency and an even load-factor. An elaborate receiver system is employed, the compressors discharging into large steel cylinders from which the mains leading to the machines using the air draw their supply. The combined capacity of these cylinders is sufficient to equal the total output of the compressor plant for nearly half an hour. Constant pressure is maintained in these receivers hydraulically, the water in the bottom of the tanks being received from an open water-tank on the hillside above the plant, at a sufficient elevation to provide the required pressure of 90 lb. All the air contained in the receivers may thus be used at

full pressure, and it is impossible under any circumstances to exceed this pressure. The receiver system permits the compressors and the motors driving them to be operated always at full load and maximum efficiency. Large variations in demand are taken care of by starting or stopping an additional compressor unit.

It will be seen, therefore, that in designing this station every benefit that might accrue from the centralization of the compressing machinery has been taken advantage of. The cost of buildings, foundations, machinery, and maintenance has been cut down to a minimum per cubic foot of air. Transmission losses between the motor and the compressor have been entirely eliminated. The apparatus is operated at maximum efficiency and the load-factor is so good and the absence of peaks so marked that the power company can afford to make a marked concession in its charge. Further, the synchronous motors employed in this plant are designed to carry their full normal mechanical load with fields overexcited so as to obtain 80% power-factor leading in the motors. With the entire plant of

1500 hp. and 80% leading power-factor in the motors. They are engine type in construction, the spiders of the revolving field being in halves, assembled directly on the shafts of the compressors. At full load they have an efficiency slightly in excess of 95%. A corresponding induction motor designed for a reasonably good power-factor would not have better than 92% efficiency. Accordingly, in this plant of 7200 hp., where there is a saving in efficiency of about 3%, or something over 200 hp., the cost of which when capitalized means a very considerable investment.

The engineers of the Anaconda Copper Mining Co. were at first somewhat fearful that these synchronous motors would not be sufficiently stable on the line, particularly if considerable power-factor correction were attempted with them, and accordingly the manufacturers agreed to guarantee successful synchronous operation without tendency to fall out of step or 'hunt' under conditions of from  $\frac{1}{4}$  to  $1\frac{1}{4}$  load with the voltage varying from 200 to 2600 volts and at various power-factors ranging from 80% leading to 100%. A maximum of  $2\frac{1}{2}$  times full-load torque with

COMPRESSED-AIR RECEIVERS, ANACONDA C. M. CO.

7200 hp. in operation, this feature will permit of enough corrective effect being obtained to greatly compensate for the low power-factor of some 15,000 hp. of induction motors operating elsewhere about the company's properties.

The synchronous motors installed at the Anaconda company's plant are built with squirrel cage windings on the revolving fields. They may in case of necessity be self-started, but are not designed primarily as self-starting motors. As there is almost always some pressure in the receiving system of the compressors, arrangements have been made to reverse the valves on the compressors and permit each one to act as an air-engine and bring its motor up to speed, after which the motor is synchronized in the ordinary manner. As a refinement, an automatic synchronizer has been included in the switchboard equipment, permitting the motor to be synchronized without any attention from the operator, when it reaches the proper voltage and speed. Should pressure in the receivers fail, due to some accident, the motors can still be started by applying alternating current to the armature windings.

As an instance of what can be done in the designing of a synchronous motor of this size, as to efficiency and stability, a description of the motors in this plant is presented. The motors are all rated normally at 1200 hp., 3-phase, 60 cycles, 2400 volts, 75 r.p.m. They have a continuous overload capacity permitting their operation at

the motors operating at unity power-factor was also guaranteed. After operating for over a year the motors have proved that they will more than meet the guarantee regarding stability made for them and have shown themselves in every way equal in operation to any induction motors, while allowing a considerable improvement in efficiency over what might have been obtained from induction motors, and at the same time permitting of large power-factor correction altogether impossible with the induction type. The determination of the Anaconda company's engineers to double the size of this plant, using motors of exactly the same design as those now installed, is good evidence of their satisfactory performance.

MINERAL WATERS in Argentina are to be investigated by the Division of Mines, Geology, and Hydrology of the Ministry of Agriculture according to a general plan which comprises the description and determination of the nature and topography and classification of mineral springs, the properties of the waters, their curative effects, and other data which will serve as a basis of legislation on the matter. It is stated that Argentina is the only country which for hydro-mineral wealth is on a par with France. The radioactive properties of the waters, in view of the great value attributed to this new form of energy by modern science, are considered a factor of great importance.

## Geology of Culebra Cut

By D. F. MACDONALD

\*The slides in Culebra cut are attributable to two general causes: (a) a primal cause, the weak and unstable geological condition of the rocks through which the cut passes, attributable only to nature; and (b) the oversteepness and height of the slopes, the blasting, and other work attributable only to man.

In the main, the weakness, and, therefore, the sliding tendency of the rock is due to peculiar local geological conditions. The presence of fossil oysters, corals, gastropods, and remains of other marine animals in the sedimentary rocks found at intervals across the Isthmus, is evidence that the Atlantic and Pacific oceans were in connection over the present land barrier during Tertiary time. During that period, islands of older rocks, like the present islands of Panama bay, showed at intervals above the shallow ocean which existed where the Isthmian land now stands.

These oldest rocks consist of (a) re-crystallized conglomerates and breccias, as found at Bas Obispo, and locally, near the Pacific. These are overlain by (b) agglomerate lava flows and tuffs, as between Empire bridge and Las Cascadas. The next younger rocks (c) are the light colored tuffs of Pedro Miguel, Miraflores, Diablo ridge, and the lower slopes of Ancon hill. Later than these are (d) the dark soft shales and marly clays, found from one-fourth mile south of Empire bridge to the Miraflores locks. Probably equivalent to these dark shales are the argillites and argillaceous sandstones of Lion hill, Gatun, and Mount Hope. The upper part of the Gatun formation seems to be equivalent to the Bohio conglomerates. Deposited later than (d) are the greenish volcanic clays, unstratified in character, and with red oxidized beds representing land conditions of deposition. This formation contains lava flows; also, lignitic shale beds, showing fossil ferns, and other vegetation, which is confirmatory evidence that while they were being formed above sea-level, swamp conditions prevailed locally. The youngest series of bedded rocks (e) have a basal bed of coral limestone, overlying which are yellowish weathering consolidated clays, a bed of limy conglomerate, and the youngest beds of limy argillite. All of the Isthmian sedimentary rocks are cut by intrusions of basic lava, mostly basalt, and by plugs of meta-breccia, pushed up cold by some of the lava intrusions. The lavas and breccias are strong, but most of the sedimentary rocks of Culebra cut are uncrystallized, loosely cemented, sheared, and cut by fissures and faults, so they are very weak and unstable. Through their interstices and joint and fault-planes they absorb a large amount of the heavy tropical rains, which further weakens them, and which increases their tendency to deform and slide.

There are four distinct types of slide, classified by the geologists as follows: (a) structural breaks and deformations resulting in slides; (b) normal or gravity slides; (c) fault-zone slides; (d) weathering and surface erosion.

The structural break and deformation slides are the most troublesome and most important. Their first manifestations are cracks or fissures, approximately parallel to the side of the cut, and from a few to a hundred yards or more, back from it, and from each other. Each fissure is usually traceable on the surface for several hundred yards, and each gradually widens with time. The next stage of this type of slide is the tilting of the large blocks toward the canal, usually accompanied by upward bulging of the bottom of the cut, opposite the moving block. For a few weeks, or even for a year or more, this tilting, settling, and bulging may continue before the real slide comes. This last stage consists in the collapse of the basal part of a moving block, due to the pressure of its upper part, and to the weakening effects of the deforming and shearing movement that it has undergone. When this stage is reached, the block rapidly disintegrates, and, in a few hours, or a few days, it

becomes a gravity slide of debris at the bottom of the cut.

The causes of this type of slide are the weakness of the rocks, and the height and steepness of the slopes. These conditions induce deformation, or almost imperceptible flow-movement of the high banks toward the excavation, with consequent cracking and shearing of the slope material, and bulging at the bottom of the cut, all of which tends to further weaken the rocks until finally they collapse.

Normal, or gravity slides, occur where the cut intersects beds of porous material lying on top of relatively impervious material, and thus causes a muddy, slippery zone to form along the contact between the pervious upper and impervious lower layers. If the latter dip toward the canal, or if there is much lateral pressure from higher ground, the material above the zone of contact is almost sure to slide. The Cucaracha and Paraiso slides are of this type, but, like most slides of this kind, they are now practically over. This type of slide, it is predicted, will not, from now on, in the progress of the work, be large nor important.

The fault-zone slides are occasioned primarily by sheared and weakened zones in the rocks, due to fault displacements. Where fault-planes are intersected by the plane of the canal slope, large masses of rock in the acute angle between the two planes generally fall into the excavation; or where the fault-plane dips, the overhanging rocks—hanging wall of the plane—often crush downward into the excavation. The most notable fault-zone slides are the La Pita slide, and that about 600 ft. north of La Pita, which, on August 20, 1912, in a few minutes, let down about 300,000 cu. yd. of material and carried away a hundred yards of the East Diversion.

The heavy tropical rains erode and trench the slopes and wash the weathered surface material into the cut. Weathering and disintegration of most of the rocks of Culebra cut is rapid, because the iron and magnesia compounds which they contain are readily oxidized on exposure to the atmosphere. The new oxides formed take up more room than the old product, and the change of volume thus brought about causes the rock to crumble and fall to pieces. These rocks also contain some soluble limy cementing material, which, when leached out by surface waters, helps along the disintegrating process. The loose surface product, which results from this rapid weathering, is swept from the slopes by the heavy tropical rains, and thus fresh surfaces are left exposed for further weathering action. Of course, the material washed into the cut in this way forms no perceptible hindrance to present excavation; still, it may be estimated that it would add about 65,000 cu. yd. per year to the sediment accumulating in the bottom of the canal. At 25c. per cubic yard for removal by dredging, this would swell the upkeep charges by \$16,250 per year. Slopes that are clothed with a carpet of vegetation are relatively free from erosion, hence tropical vegetation will be encouraged to cover the slopes of the canal with its abundant growth, that washing by tropical rains may be minimized.

It is believed that the rock conditions along the canal will limit the slides within certain fairly definite bounds, and that when the slopes have been reduced to the proper angle, the slide problem will be practically solved. This angle will vary from almost perpendicular in the case of strong lavas, to one in five for the weaker rocks, or even one in ten in a few extreme cases, where deformation and faulting have been pronounced. Almost the only remedy of practical importance in the slide problem is to lessen the weight of the high weak slopes from the top, so as to reduce the tendency to slide, and to prevent, if possible, breaks and deforming movements. Slopes which have not moved will stand at a much steeper angle than those of the same material which have been sheared, cracked, and bulged by deforming movements. The first estimate for the excavation of Culebra cut designed slopes that were much too steep for the weak nature of most of the material through which the canal was to be excavated, but though slides of considerable magnitude are yet to occur, the sliding period will eventually be brought to a close, and the ultimate completion and successful operation of the canal cannot possibly be in any danger from slides.

## Disposal of Tailing at El Tigre, Sonora

By DONALD F. IRVIN

The cyanide residue discharged from the plant of the Tigre M. Co. is an all-slime product, about 85% of which will pass a 200-mesh screen. Of the ore before grinding, about 60% is a natural clay slime, the rest requiring re-grinding in tube-mills. This product is handled by Kelly filter-presses, and from them flows to waste.

In common with many mining properties operating cyanide plants in Mexico, the Tigre M. Co. has been obliged to prevent the injury of neighboring stockmen and ranchers by the poisonous effect of cyanide solution in the tailing discharged from its reduction plant. The stockmen are quick to resent such injuries, and in consequence cyanide residues must be judiciously handled, even in districts that are practically a wilderness, if lawsuits and injunctions against operation are to be avoided, to say nothing of bills for cattle poisoned by creek water. It should also be recognized that the Mexican bench, in decisions rendered

Various plans for storing the cyanide residue were considered, as that was decided to be the only desirable plan. Discharging the tailing dry and stacking with a belt-conveyor, in the manner used by the Zambona M. Co. in Sonora, was not feasible, as there is but very little storage room close to the filter plant. Damming the canyon itself is a dubious expedient, as it has a heavy grade and is not wide; furthermore, the summer rains are most violent, and at times approach cloudbursts in their intensity. Hence it was decided to retain the slime upon a high mesa, about two miles down the canyon from the cyanide plant. This mesa lies some 150 ft. above the stream-bed, and is about 40 acres in extent, about one-half of which is adapted as a unit for a reservoir site.

Knowing from previous experience elsewhere, as at Goldfield, that slime dams may be built up from their own semi-dried mud, used as wall material, the work upon the dam was started in the winter of 1911-1912, and also upon excavation of a ditch along the canyon wall from the filter plant to carry the slime to the damsite. The first work was the throwing up of a low preliminary earth and rock dam to hold the first of the slime, until it became dry enough to be useful as wall material. A low ridge in the centre of the reservoir site, running at right angles to the face

TAILING POND.

TRESTLE FLUME.

in suits tried in southern Mexico, has affirmed the prior right of the agriculturist as opposed to the miner, so the rancher has the weight of the law with him in his contentions.

When cyaniding was begun at El Tigre this slime product was discharged directly into Tigre canyon, which is the bed of a torrential mountain stream, in the belief that the natural decomposition of the cyanide contents would be effected before reaching the Bavispe river, some 15 miles distant. The latter stream, during most of the year, carries a large volume of water, and supplies the municipality of Oputo, an irrigated district, some 60 miles south, and other water users as well. A very short run proved that there was poisoning of local livestock in Tigre canyon, so the stream-bed was immediately fenced with barbed-wire. This was possible, as the Tigre M. Co. owns all the land intervening, although it is used as a cattle range by various Mexican and American stockmen on both sides of the canyon. As a preventive, it served its purpose against cattle poisoning in the canyon, but the question of the quantity of cyanide in solution at the junction of the Tigre canyon and the Bavispe river was vigorously raised by the people of Oputo. In their minds, their case was strengthened by an epidemic of typhoid fever, which incited the management of the Tigre M. Co. to further measures designed to absolutely remove all chance of pollution of the canyon water, and coincidentally avoid any legal clash with the irrigation districts on the Bavispe river, although there never was a trace of cyanide found in the latter stream at any time. Solution samples taken in Tigre canyon 50 ft. from its junction with the Bavispe failed to show a trace of cyanide.

of the dam, divides the storage room into two parts, and it was used from the beginning as a means of dividing the pond into two basins, one receiving the flow of pulp while the other is thickening.

Inasmuch as settling recovers a fair amount of solution, in spite of loss by evaporation, and this solution contained small quantities of precious metals, cyanide, and lime, a decanting pipe was placed in each bay of the reservoir and the decanted solution was run through a zinc-box connecting with a triplex Aldrich pump, which can either return the solution to the mill or through a by-pass into the slime ditch above the point where it enters the dam. The pump was installed as a means of recovering all the water possible in the dry season, as well as for the sake of the solution itself. However, the mill is now running on a much smaller water consumption than was at first thought possible, and, as the natural water-supply is more abundant than formerly, the pump is used only as an adjunct to natural agitation of the thick slime tailing in the ditch as it comes from the filter plant to the reservoir. By dilution it thus effects a slight additional recovery of dissolved metal, which is caught in the zinc-box, although, as a rule, this is so small that the recovery thus made is quite insignificant. The dissolved metal in the pulp is now much less than was thought at first could ever be attained, hence the recovery in the zinc-box is small. The amount of solution decanted from the surface of the reservoir will vary with the seasons, naturally being greater in the rainy months—a low figure being 3 gal. per minute and a high being 12 gal. per minute. Percolation is now negligible, the other sources of loss of water being from evaporation and retention by the slime itself.

The essential benefit of the arrangement is that, beyond dispute, all cyanide tailing is kept from polluting the natural waters of the district, and the tailing is preserved on ground belonging to the Tigre M. Co. Although at present further metal recovery is not practicable by current metallurgical methods (they assay only 1.25 to 1.50 oz. silver per ton), at some future time they may represent a live asset. The discharged residue from the filter plant is very thick, and unless diluted by a small stream of water that enters the launder would not flow in the ditch, in spite of its heavy grade, which is 1 in 9, or about 11%. A series of determinations over a considerable period of time on the pulp issuing from the filter plant show an average moisture ratio of  $\frac{1}{2}$  to 1.

Before the additional water was added to the slime ditch the pulp would often back up in the ditch and overflow at the turns, and at every culvert that crossed the small side arroyos the slime would leap over the side of the launders. Raising the dam walls, care of the ditch and of the pulp involve some labor, and for this purpose three Mexican laborers live at the damsite and do all this routine work. These men are paid P2.50 and P2.25, and are the only labor charges incurred in maintaining the work. The carpenter work required in building the distributing launder along the crest of the dam was, of course, charged to construction.

In operating the dam it is thought best to discharge the slime as near the dam itself as possible, so that the heavier deposit may form there and the thinner part gravitate to the back of the pond, where the decanting pipes are placed. The photographs show the arrangement of discharge of the slime into the dam through a trestle flume, and also the manner in which the dam is built up. The trestled flume was chosen as a means of conveying the sluggish pulp along the crest of the dam and discharging it at that point with the minimum of labor and time lost in alterations, as the level of the slime pond rises.

Seeking added stability for the dam, an auxiliary dam was started below the main dam, after impounding of tailing had begun. This was commenced in much the same manner as the main dam was built, save that the slime was run into the second catch-basin through holes made in the wall of the big dam and allowed to flow in a series of small sections.

This lower dam is 50 to 75 ft. from the face of the main dam and is kept about 7 ft. lower. The crest of the main dam is 2 to 3 ft. thick and is seldom more than 1 or 2 ft. above the surface of the pond. The thickness of that portion of the wall that is below the surface of the slime in the pond is indefinite, for it is homogeneous with the slime of the pond itself, and hence it may be considered to be any thickness. This was shown by a washout during the past rainy season, when a crevasse was formed in the face of the dam during a tremendous downpour. The part washed out was narrow and deep, and showed the slime to be uniform, leathery, and compact from top to bottom, and this condition persisted for a number of feet back from the face of the dam. At the present writing (about November 1, 1912) the main dam holds, in round numbers, 60,000 to 65,000 tons of tailing and the crest of the dam is about 20 ft. above the ground-level at the highest point.

This method of tailing storage has no essential feature of special novelty, although it is unlikely that such a long and devious ditch is in use elsewhere to convey the tailing, and the remarkably coherent Tigre slime enables the dam to be built to a height that would otherwise be unsafe. In this connection it may be added that the face of the dam may be built up so as to impound tailing for at least three years at their present rate of increment, before it will be necessary to begin the construction of a second dam on the more roomy site immediately below the present one.

THE October output of the Rand mines was valued at \$16,320,000, against \$14,400,000 for the same month of last year.

## Antimony Mining in New South Wales

By J. E. CARNE

\*Antimony mining ranks fourteenth in the New South Wales mineral industry in total value of production to end of 1910. Owing, however, to unstable market conditions, it has never assumed a permanent character, the output resulting chiefly from spasmodic efforts during boom periods of inflation, with intervening seasons of depression and almost cessation. Under local conditions, even normal prices afford but modest profit when the metal is unassociated with gold. Hence mining for antimony alone practically ceases when market depressions occur. The intermittent character of the industry is best exemplified by the following analysis of the output: Boom prices in the periods 1880-1882, 1890-1894, and 1906-1907 were accountable in ten years for an output valued at £245,644, as against £57,215 for the remaining period of the duration of the industry, which dates from about 1874. During the brief boom of 1906-7 the local value of 50% antimony ore rose to £30 per ton. During the periods of depression, values have receded to even £5. In consequence of the limited demand in 1909 and 1910, the local production amounted to only 95 tons 9 cwt. and 96 tons 17 cwt., respectively, chiefly as a secondary product in gold mining. As an index to ordinary market values of antimony, compared with boom figures, the following averages have been computed from an interesting table of the average monthly prices of antimony in New York for 1901 to 1909, inclusive. These disclose remarkable uniformity when the boom years (1906-7) are excluded. For the seven years 1901-5 and 1908-9 the average price works out at 8.29c. per pound, while for the boom years mentioned the average is 18.96c. The position was no better in 1910, notwithstanding the duty; the production was believed to be less than 75 tons of ore.

In the early eighties antimony reduction works were established at Carangula, in the Macleay River district, at Hillgrove, and Metz. Works were also started at Taylor's Arm, in the Nambucca district, but for a number of years these have been abandoned. During the recent boom, 1906-7, a smelting plant was built by the Metals Smelting Co. at Balmain, and about 32½ tons of antimony produced, but these works closed when prices fell. In the beginning of gold-mining operations at Hillgrove, great difficulty was experienced, owing to the association of antimony with the gold. In 1882-3 Messrs. Newbery, Vautin, and others patented a process for separation of these metals and saving of the antimony, the antimony being volatilized as oxide and recovered in suitable flues, the gold being recovered from the roasted residues by ordinary crushing and amalgamation. The method adopted subsequently at Hillgrove was of this character.

The principal antimony deposits in New South Wales occur near the junction of slate and granite at Hillgrove; at the Macleay river in Permo-Carboniferous or Carboniferous sandstones and claystones; at Nambucca and Bellingen rivers in altered sandstones and slates and schistose rocks, traversed by large dikes; and at other places in Devonian slates and sandstones and gneissic granite.

MACHINES used in mining coal in the United States in 1911 totaled 13,819, an increase of 565 over 1910. Pennsylvania's production of machine-mined coal was 69,131,923 short tons, or 47.76% of the total; and Ohio's production was 26,556,630 tons, or 86.33% of the total. Although the total production of bituminous coal in the United States decreased from 417,111,142 tons in 1911 to 405,757,101 tons in 1910, the quantity undercut, or otherwise mined by machines, increased from 174,012,293 to 177,971,976 short tons.

DISCOVERY of petroleum deposits on the island of Chiloe, in Chile, has been confirmed by the governor of that island.

\*Abstract by the *Australian Mining Standard* from Bull. No. 16, Mineral Resources Series, New South Wales.

## Mining Progress in Rhodesia

### SOUTH AFRICAN CORRESPONDENCE

No other mining district in Southern Rhodesia has come to the front so rapidly as Gatooma. Five years ago there was merely a gangers' hut by the railway track and one or two prospectors' camps in the vicinity to denote that such a place as Gatooma existed. Today there is a large flourishing township, and within a radius of 21 miles no less than 37 gold mills are working. In addition, mine plants are in course of erection and a number of ventures are approaching a stage at which they will require larger plants, so that a further increase in the gold output of the district in the near future may be expected with confidence. By far the most important area in the Gatooma district, is the Eiffel Flats, years ago a favorite hunting ground of F. C. Selous. Today the Eiffel Flats present an animated appearance and in a year there will be even more activity.

The chief property on the Eiffel Flats is the Cam & Motor. Here two extensive veins have been developed, one in the Cam block and one in the Motor claims. As a consequence

MAP OF SOUTHERN RHODESIA.

of the present development work it is estimated that there is developed in the two mines 1,000,000 tons of ore of an average assay value of 46s. per ton. Most of this is in the Motor, where development has been carried down to the fifth level and a large body of high-grade ore has been proved. Recent work has given results of exceptional interest. The first cross-cut is at 105 ft. south of the main shaft and shows a vein 14 ft. wide averaging 33s. 1d. per ton. At 225 ft. the vein is 91 ft. wide, assaying 44s. 2d. Production will commence next year. The method of treatment adopted is somewhat similar to Western Australian practice. A recovery of about 85% is expected from this method. The capacity of the plant will be 180,000 tons per year, but it will be designed with a view to early increase of capacity. It is expected that the equipment will be ready for work about next June, and it is certain that the Cam & Motor will advance to the front rank of Rhodesian mining.

Although the Giant Mines Co. at Gadzema is making a profit of £10,000 per month, the underground position can scarcely be termed satisfactory. At about the sixth level, between the old and new main shafts, a big lenticular mass of ore was found. The width of the orebody at this depth was as much as 140 ft. in places early in 1911, but it was found to pinch below the sixth level. Extensive diamond-drilling operations have been carried out to find the vein in depth, and the consulting geologist of the company, G. S. Corstorphine, believes that the work so far carried out "has very far from exhausted the possibilities of the lode existing below the seventh level." The third bore-hole put down intersected material somewhat resembling the orebody. Bore-hole No. 7 was put down to cut this and bore-hole No.

8 was directed vertically in a zone not yet explored and drilled to a greater depth than any previous hole. It is now announced that three bore-holes have proved the presence of an acid dike below the seventh level, with a strike parallel to the orebody. They also have proved a belt of mineralized schist of the same type as the orebody, with a low gold content and lying on the upper side of the dike. No. 11 is now being drilled to cut the schist body more centrally and is expected to decide whether this body is a news lens of auriferous rock, or is the faulted portion of the orebody in the upper levels. Results from the No. 11 hole will be awaited with keen interest.

For the past 18 months an important prospecting expedition has been at work in a little known portion of Rhodesia. This is the southern portion of northeastern Rhodesia, where the North Charterland Exploration Co. owns much territory. This company organized an expedition in the latter part of 1910, and after months of patient work a promising gold deposit was found at Madjimoio, close to the Anglo-Portuguese frontier. After a certain amount of work had been carried out it was decided to erect a small testing plant, and accordingly a Tremain steam stamp battery was ordered. The latest report is that rich specimens of gold and copper are being found. There seems, however, to be considerable doubt as to whether any

MILL AT GIANT MINES.

of the mineralized areas contain persistent orebodies. Much more work will have to be done before this point is proved, and now that the rainy season is coming on it is improbable that much will be done before next year. However, the discovery of promising gold and copper deposits in northeastern Rhodesia is at least interesting, since only one gold mine is producing in the whole territory; the Sassare in the Luangwa valley. Northeastern Rhodesia is rather inaccessible. The capital, Fort Jameson, is more than 300 miles distant from the nearest point on the railway and all transport is by porters. The country is unhealthy and in the absence of any profitable industries it is probable that no serious attempt to develop will be made for years to come.

## Increased Gold Production in Mexico

Mexico was fourth in rank among the gold-producing countries in 1911, according to the figures of the U. S. Geological Survey, the output for the year being \$29,196,000. This was an increase over the 1910 figures of more than \$4,000,000, despite the unsettled conditions which prevailed in some portions of the Republic during the year. With a return to settled conditions and the continued introduction of modern mining and metallurgical methods into Mexico leading to renewed development of the great metal resources of the country, the gold output may be expected to increase still more rapidly.

AT THE mines of the Sulitjelma company, Norway, the Elmore vacuum plant produced 1150 tons of copper concentrate during the month of October.

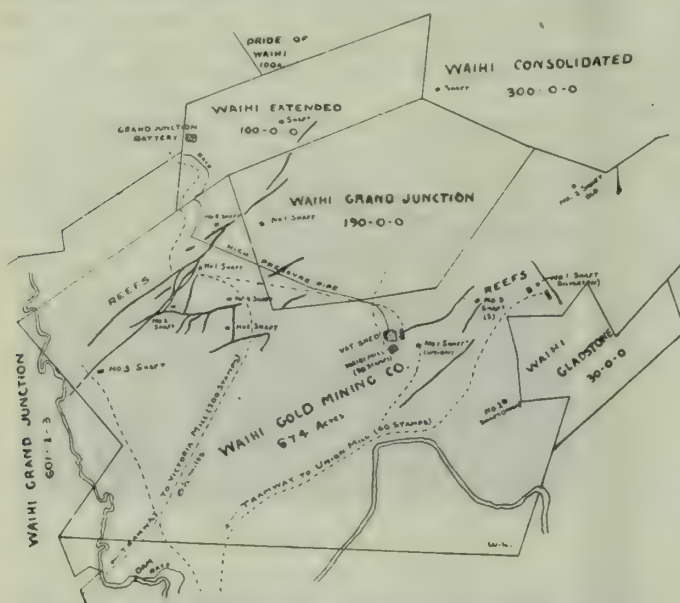

# Precipitation of Gold and Silver by Carbon

By R. K. COWLES

\*This paper is the outcome of experiments carried on and experience gained at the Waihi-Paeroa Gold Extraction Co.'s tailing plant at Waihi, New Zealand. The plant was erected to treat accumulated tailing which had been discharged into the Ohinemuri river by the Waihi stamp-mills. The Ohinemuri river is a common sludge channel for all mining debris, tailing, and ashes from the power-plants, the last being the cause of occasional high residues which gave so much trouble to the management.

The tailing was dredged from the bed of the river into barges by means of a Pohle air-lift, the power being supplied by a 13 b.h.p. Tangye oil-engine driving an air-compressor and a centrifugal pump. The sand was elevated from the barges by bucket-belt elevators over screens, to

PRINCIPAL WAIHI MINES, NEW ZEALAND.

eliminate large particles and rubbish, into storage hoppers, and from there fed direct into four C. Judd Ltd. tube-mills. The method of treatment was fine grinding in a weak cyanide solution, agitation in Brown and McMiken tanks (Pachuca), filtration with turn-over vacuum filters, and precipitation with zinc shaving.

The comparatively high content of the residue in gold gave a great deal of trouble, and it was not until repeated experiments were carried out that the cause of the trouble was identified. While the content in silver remained stationary, the gold fluctuated greatly. To overcome this, finer grinding was tried, with poor results, except that more silver was recovered—the gold still remaining too high. It was well known that carbon would precipitate gold and silver, but its selective action was not known. When fine grinding did not give the desired result, other methods had to be sought. Knowing that there was a variable amount of half-burned coal among the tailing, it was decided to experiment with carbon.

A heavy freshet occurring at that time gave the opportunity on a large scale, as it brought down a large amount of half-burned coal. On the newly deposited tailing experiments were carried out, and it was found that silver residue, just after grinding, was normal, while the gold was slightly high. Samples were then taken every day from the B. and M. tanks and assayed, with the result that the gold content unmistakably increased while the sil-

ver content decreased until such a time when practically all the gold was precipitated, then the content of the silver residue started to rise, thus showing that the carbon had no apparent effect on the silver until nearly all the gold was precipitated. The following are the results of a few assays, showing the action of carbon on gold and silver in cyanide solutions. The samples were first taken from the overflow from the classifier, and then daily from the B. and M. tanks.

Sample.	Gold, oz.	Silver, oz.
No. 1.—From overflow .....	0.088	0.908
B. and M. tanks:		
first day .....	0.098	0.658
second day .....	0.102	0.634
third day .....	0.108	0.628
fourth day .....	0.112	0.672
No. 2.—From overflow .....	0.060	0.860
B. and M. tanks:		
first day .....	0.068	0.672
second day .....	0.088	0.654
third day .....	0.096	0.604
fourth day .....	0.096	0.684
No. 3.—From overflow .....	0.044	0.680
B. and M. tanks:		
first day .....	0.062	0.620
second day .....	0.084	0.610
third day .....	0.100	0.650
fourth day .....	0.100	0.814

No. 4.—Experiments were then made with gold and silver solutions in which ground clinker was placed, the whole being agitated for two days, with the following result:

	Gold, oz.	Silver, oz.
Before agitation .....	0.046	0.642
After agitation .....	0.013	0.504
Precipitated .....	0.033	0.138

No. 5.—Unconsumed coal-dust was also placed in a gold and silver solution and agitated for two days, but no precipitation occurred.

No. 6.—A sample of half-burned coal from the river was assayed, and was found to contain 0.102 oz. of gold and 0.604 oz. of silver.

No. 7.—A sample of charcoal (in small lumps) found floating in the lime tank was assayed and found to contain 1.760 oz. gold and 1.792 oz. silver.

This showed that it was imperative to eliminate the charcoal associated with lime used for settling purposes.

By comparing the time of the river freshets and the slime residue of the tailing taken at that time, it was found that the residue was higher than at any other period. From this it was concluded that fresh carbon precipitated gold and silver more freely than old.

To eliminate the carbon two 6-ft. Union vanners were installed. Though these were overtaxed, the desired result was at once obtained. Besides removing the carbon, the light river sand was also removed. The output of the plant was 80 tons per day, and that amount was run over the vanners. The vanners were driven at about 120 revolutions, with a belt travel of 6 ft. per minute, and with a fall of 8 inches in the whole length. The distributing-box was placed 18 in. farther down than is usual, while the pulp discharged from the lower side. The water-distributer also was placed lower down the table. The sand was from  $\frac{1}{4}$  to  $\frac{3}{8}$  in. thick as it came comparatively dry over the head, where it was washed off with a series of solution jets into a launder.

In the assays No. 1, 2, and 3 there was no apparent precipitation of silver until nearly all the gold was precipitated, but in the experiment No. 4 and assays No. 6 and 7 silver was shown as being precipitated in equal and greater quantities than gold. From this apparent contradiction it is assumed that, while the silver was being dissolved, a very small amount was being precipitated, showing that the dissolution of silver up to a certain point was quicker than the precipitation.

\*From the *Proceedings* of the Australasian Institute of Mining Engineers.

End of the Simmer & Jack

After a chequered career of about seventeen years, the Simmer & Jack East mine has gone under, its failure to keep its head above water being due to a combination of natural and artificial causes. Situated in a low-grade and broken area, the yield has never equalled expectations while, like other properties in the same area, it had to carry a huge capital of ordinary and debenture scrip. It is a unique experience on these fields to see a fully equipped gold mine like the Simmer East put up for sale to the highest bidder, because, as a matter of fact, not more than half a dozen gold mines through the long length of fifty miles have proved failures, or been unable to meet their liabilities and pay dividends at some time or another. The property was controlled and nursed by the Consolidated Gold Fields of South Africa until it was considered injudicious to continue that policy any longer, and following the usual mode of procedure with unsatisfactory or exhausted properties, it is to be absorbed by another under the same control. When put up for sale at auction the other day, the Knights Deep company became a conditional purchaser for a quarter of a million sterling, the necessary amount being supplied by the Consolidated Gold Fields of South Africa to the purchasers for twelve months, free of interest. The Knights Deep has an option to work the mine for a year on certain conditions and to purchase during that time for 100,000 shares to be issued to the Consolidated Gold Fields. Here, then, is a mine with a nominal capital of £700,000, some of which shares have been subscribed for at double their par value and upon whose property debentures to the amount of £900,000 have been issued, acquired by a neighboring concern for 100,000 shares of the nominal value of £1 each. Seeing that the mine is equipped with a 200-stamp mill and can earn working profits ranging from 3s. per ton upward, having quite recently made a profit of £6000 per month, the terms upon which the Knights Deep has acquired the property are certainly advantageous, and will probably result in the Simmer East being purchased on the terms offered during the continuance of the option.

Mineral Production for 1911

In spite of the decrease in the production of iron, the value of the total mineral production of the United States for 1911 reached the enormous figure of \$1,918,184,384. Of this the value of the metals was \$672,179,600, the remainder representing the non-metals. Coal led the list with a value of \$626,366,876; pig iron was second, with a value of \$327,334,624; clay products third, \$162,236,181; copper fourth, \$137,154,092; and petroleum fifth, \$134,044,752. The following table shows the output and value of the ten leading mineral products during 1911.

	Quantity.	Value.
Coal		
Bituminous.....short tons..	405,757,101	\$626,366,876
Anthracite.....long tons..	80,771,488	
Pig iron.....do.	23,257,288	327,334,624
Clay products.....		162,236,181
Copper (from domestic ores).....	1,097,232,749	137,154,092
Petroleum.....barrels	220,449,391	134,044,752
Gold.....troy ounces	4,687,053	96,890,000
Stone.....		76,960,698
Natural gas.....		74,127,534
Cement.....barrels	79,547,958	68,705,136
Lead.....short tons..	406,148	36,553,320

These and other figures of production are discussed in an advance chapter from 'Mineral Resources of the United States' for 1911, by W. T. Thom, of the U. S. Geological Survey. While the total value for 1911 is about \$70,000,000 less than for 1910, it is greater than that of any other year except the banner year of 1907, when the \$2,000,000,000 mark was passed. Indeed, it is only in the last thirteen years that the mineral output of the country has been above the billion-dollar mark. Fourteen years ago, in

1898, it was only \$724,272,854, and ten years before this, in 1888, it was but a little over \$500,000,000.

In spite of the decrease in the total value of the mineral output in 1911, a considerable number of products showed a marked increase, 45 of the minerals for which statistics were collected by the Geological Survey having increased in production, against 21 which showed a decrease. Thus, anthracite coal increased to the value of nearly \$15,000,000; lead and zinc each increased more than \$3,500,000; silver increased \$1,750,000; petroleum more than \$6,000,000; natural gas nearly \$3,500,000; and sulphuric acid nearly \$3,000,000. The products showing the greatest decreases were pig iron, more than \$84,000,000; bituminous coal, about \$18,000,000; clay products, nearly \$8,000,000; and cement, \$2,000,000, although the amount of cement produced was 1,750,000 bbl. in excess of that produced in 1910.

Goldfield Consolidated Report

During the month of October 1912 the total production of the Goldfield Consolidated Mines Co. was 30,573 tons, containing \$456,779, or an average of \$14.94 per ton, according to the report of C. D. Kaeding, assistant superintendent. Of this, 29,782 tons was milled with an average extraction of 90.48%, and 791 tons was shipped of an average value of \$20.24 per ton. The net recovery from all ore was \$13.57 per ton. The total net realization was \$242,163, or \$7.92 per ton. During the month, 4084 ft. of development work was performed. The total cost of mining, development, transportation, milling, office and general expense was \$5.67 per ton, distributed as follows:

Mining (including stoping and development).....	\$3.16
Transportation .....	0.07
Milling .....	1.93
Marketing .....	0.05
General expense .....	0.37
Bullion tax .....	0.04
Marketing ore .....	0.11
Total cost of operation .....	\$5.73
Miscellaneous earnings .....	0.06

Net cost per ton.....\$5.67

In the Combination the 136-BX stope, on the second level, was extended, and produced 505 tons of ore averaging \$26.50 per ton. The 246-C stope, 450 ft. east of the shaft between the third and fourth levels, was extended and produced 518 tons of ore averaging \$38.10 per ton. The sill being cut on the orebody in the 414-C raise produced 276 tons of ore averaging \$32 per ton. The 402-DX raise being run from the 492 intermediate below the fifth level, 250 ft. east of the shaft, discovered ore and produced 88 tons averaging \$34.60 per ton. In the Mohawk the 40 drift on the 150-ft. level, going north from the Sheets-Ish workings, produced 185 tons of \$26.40 ore. The 107-X drift, driven in the hanging wall under the Sheets-Ish workings, on the 250-ft. level, disclosed a body of ore which has not been opened at any other point, and produced 82 tons averaging \$28 per ton. This new orebody should produce a considerable tonnage of good grade ore. The 215-PX stope, between the first and second levels, 560 ft. northwest of the shaft, produced 500 tons of \$30.20 ore. The southern end of the 307 stope, between the second and third levels, was extended and produced 1160 tons of \$26.50 ore. The 490-R stope from the intermediate between the third and fourth levels, and just south of the big 354 stope, was highly productive, yielding 1738 tons of ore averaging \$218.40 per ton.

The 420-S stope in the Clermont, between the 600 and 700-ft. levels, just south of the 413 sill, produced 814 tons of \$55.60 ore. This is the downward extension of the big 413 orebody and will produce a large tonnage of excellent grade ore. The downward extension of the 510 orebody, between the 750 and 900-ft. levels, produced 443 tons of \$23.20 ore. The 700-F and G stopes, between the 1200-ft. level of the Grizzly Bear and the 1000-ft. level of the Clermont, produced 719 tons of ore averaging \$67.60 per ton.

The 802 stope on the 1300-ft. level of the Grizzly Bear was extended and produced 227 tons of \$45 ore. The stope carried up from the 220 drift in the Jumbo No. 2 produced 791 tons of \$41 ore. A winze has been started on this ore-shoot, and the south drift on the 300-ft. level is being advanced to open the downward extension of the ore.

## Eastern Metal Market Review

During November the Eastern metal market was characterized by flurries of activity with very little sustained buying. The best movements were in tin. While basic conditions are good, and consumption very fair indeed, the market within the month has been adversely affected by the disturbed political conditions abroad, the presidential election, two holidays, and the tendency which develops toward the close of the year of curtailing heavy buying in order that yearly statements may be made as favorable as possible. As for the foreign market, it must be expected that conservatism will prevail until there is less war-talk, with its consequent effect on markets and finance. The general tone of the market is optimistic, as it is recognized that buying comes in waves rather than in a steady stream. There have been no heavy declines in the month except in lead.

### COPPER

While there was at one or two periods in November fair buying movements in copper, quiet prevailed at the end of the month. Domestic consumers, by reason of contracts, were not obliged to enter the market heavily during the month, and their needs are covered for at least a part of December. They are not so well supplied, however, that they can put active buying far off into the future, and favorable prices probably would start activity. About the middle of the month buying for export got a good start, but a renewal of fear that the Balkan war would embroil other than the original contestants halted the movement, and to the present foreign buying has not been resumed with any force. In this connection it may be mentioned that exports of copper for the month, up to and including November 30, totaled but 18,771 tons, the lowest for any corresponding time in two years, and an indication that Europe has bought less copper than was supposed, also that she must have a goodly store of the metal on hand. Prices in November advanced, the month setting in with a quiet market and quotations for 're-sale' or 'speculative' lots of electrolytic ranging down to 17¼c. f.o.b. New York, cash, and 17¾c. delivered, cash 30 days, prices which prevailed but a few days when they advanced with a decidedly improved demand. The increase in stocks of 13,679,377 lb., as shown by the copper producers' statement for October, had little effect, as the figures had been anticipated and discounted. The upward trend in prices continued and caused consumers to again become reluctant to buy and trading eased off again. Then came the short-lived selling to Europe heretofore mentioned. Today finds the principal agencies holding to full prices of 17½c. cash, New York, for electrolytic, although the metal could probably be obtained from second hands at 17¼c. cash, New York, for January to February delivery, and there is a tendency toward further weakness. While the manufacturers of brass and copper products are doing a satisfactory business, the rush has subsided and they are approaching a normal state of activity as a result of curtailment which has been noticed about election time. The Waterbury average or price paid for copper in October by large consumers in the Naugatuck valley, Connecticut, is 17¾c. W. A. Clark is quoted as saying that he thinks the copper outlook good, despite the present dullness; also that producers do not want to see prices go higher. He pointed out that at the present rate of consumption there is only about two months' visible supply of the metal in the world.

### TIN

Statistics available on November 1 showed that in October there had been delivered into United States consump-

tion 3850 tons of tin, a very fair quantity in view of the dullness of the market in that month. November opened with moderate sales, and the first ten days were quiet, but from November 10 to 16 there was the best demand for many weeks, and from 700 to 800 tons, mostly for spot and nearby, changed hands, the prices ranging around 50c. or lower. It was demonstrated during this period of activity that when tin exceeds 50c. buyers are disinclined to enter the market. In the week from November 17 to 23 there again was a big volume of sales very quietly negotiated which totaled over 1000 tons, the selling beginning at 49½c., the larger proportion of business being for deliveries running ahead to April, with the bulk for February, while considerable spot metal was taken also. This period of activity was brought to an end by renewed war talk abroad of a disturbing kind, which caused a reaction in London, and this caused lower prices in New York and a loss of confidence among buyers; but inquiries are coming forward again. Deliveries into consumption in November were officially reported at 4300 tons, and the amount available is estimated at 5100 tons. In stock and landing November 30 there was 1559 tons of tin. The auction sale of 2700 tons of Banca tin in Amsterdam, Holland, on November 28 realized a price equivalent to 49.55c. per pound c.i.f. New York.

### LEAD

The American Smelting & Refining Co. made two reductions in the price of lead in November, both of which were in entire accord with the expectations of the trade. On November 4 the price was cut \$7 per ton, to 4¾c. per pound New York, which the other interests followed. It was said that so great was the dullness even following the decline that there were more sellers than buyers. November 21 the largest interest announced another reduction, which also was followed by independents, to 4½c. New York. With a season approaching in which demand usually is dull and competition still keen, the feeling continues unsettled.

### SPELTER

This metal has hovered around 7½c. New York during the month, sagging a little at times, but recovering. Reports were current early in November that the United States Steel Corporation had placed orders for 2000 tons of foreign spelter to be sent abroad again in finished products, thereby enabling the company to obtain the advantage of the drawback duty. The activity of the galvanizers and brass mills has meant a large consumption of spelter, a good part of which was contracted for at higher prices than now prevail. It has been predicted that there will not be any substantial declines in price in the near future in view of the approach of cold weather, which ordinarily causes interference with production.

### ANTIMONY

In the early part of the month there was considerable profit-taking on the part of dealers in antimony who undersold the import prices of 10½c. for Cookson's, 10c. for Haslett's, and 9½c. for Chinese and Hungarian grades. The re-sale prices were from ⅓ to ¼c. lower. Toward the end of the month prices were still lower for re-sale lots, and those quoted were: 10¼c. for Cookson's, 9½ to 9¾c. for Hallett's, and 9 to 9¼ for Chinese and Hungarian.

### ALUMINUM

The market for this metal has been firm throughout the month, and because of the inability of large interests to supply the metal for early delivery considerable foreign aluminum has found a market at good prices. In fact, aluminum has been much inquired about, both in ingot and product form. A representative of a leading interest said recently that his company was as busy as it cared to be. The statement is borne out by inquiries from consumers as to where the metal can be procured. Vast quantities of it are going into cooking utensils, of which the sale is being pushed, while the automobile industry is a great consumer. Prompt delivery aluminum is quoted at from 26 to 27½ cents.

## Discussion

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment. Insertion of any contribution is determined by its probable interest to the readers of this journal.

### Sticking to the Job

The Editor:

Sir—It seems to me to be not at all surprising that many mining engineering graduates find other lines of endeavor more attractive, especially when they see nothing better ahead of them than the job of shoving a transit. I am one of the older graduates and can boast of a variety of experience in different kinds of jobs as miner, surveyor, assayer, instructor, superintendent, and consulting engineer, and after some thirty years of observation, I have become impressed with the conviction that the greatest possibilities for the graduate are on the practical end of the mining business. Many are trying it, and some have met with enviable success. It is a tradition established for ages with the average mining captain that "No dam man can show me anything in my mine"; and no matter how many thousands of dollars the engineer sees wasted in a year underground, any suggestion which he may make for improvement is met with the declaration, "It can't be done." Some engineers complain that no suggestion is given any attention, especially on the part of the directors, unless it comes through the man underground. Then why not become the man underground yourself, if you are strong enough to stand it? And if you are not strong enough or willing to stand it, the other fellow will certainly have the advantage. There may be some danger if you stick to a job too long that the job may stick to you.

CILMINEER.

Houghton, Michigan, November 18.

The Editor:

Sir—The illustrated joke on 'sticking to the job,' in your issue of October 19, is humorous and worthy of a smile, but, like most jokes, should not be taken too seriously, as 'Sonorense' appears to have done in his communication to you in your issue of November 9. 'Sticking to the job' has more significance than most young men appear to realize. On leaving the college with his diploma in his trunk, he may think that his days of study are a thing of the past, whereas the exact opposite is the fact. He must stick to his studying. The man who expects to succeed as a mining engineer must be willing to stick to his present job until a better is offered; he must be willing to spend ten or twelve hours in his employer's work, and then two or three hours in studying the mining magazines and latest books on mining, thus keeping abreast of the times on the best practice of mining all over the world. Unless he is willing to 'do this he had better choose some other vocation. There is room at the top, but this applies only to the man who succeeds. It avails nothing for a man to declare that he is 'unlucky' or that he has no 'pull.' He will probably have to suffer many hard knocks, and see many men moved ahead of him, but if he be a good student, a hard worker, and perseveres to the end, the chances are very much in favor of success being his portion.

S. F. S.

Charcas, S. L. P., Mexico, November 15.

### Mining Conditions in Antioquia, Colombia

The Editor:

Sir—My attention has recently been called to a letter published in your issue of October 26, 1912, signed by Louis L. Maire, on 'Mining Conditions in Antioquia, Colombia.' Mr. Maire's letter is apt to give a decidedly erroneous impression of mining conditions in Colombia, and he indulges in exaggerations which are at variance with the experience of others in that country. Mr. Maire states "Antioquia is

undoubtedly a rich country in minerals. Most of the streams carry gold in quantity that in California would be considered profitable to work." He then goes on, however, to exaggerate the difficulties naturally encountered in a new and undeveloped country, but ignores the fact that several million dollars of gold are being annually extracted from Antioquia mines, and that while there are several important enterprises, a very considerable part of this production comes from mining on a small and primitive scale.

But the most misleading statement is that "clear titles to property are almost impossible to secure." This is, of course, rank nonsense. Nor is it any trouble to denounce and secure adjudication of a mine. I have now in my office under examination several titles of mines in Antioquia, which were discovered and located (by giving a preliminary *aviso* to the Alcalde or Mayor) on January 31, denouncement before the Governor of the Department made in February, possession given by the Government in July, and the definite title issued on October 30 of the same year. All these proceedings were taken by Americans.

The fees are very small; the denouncement fee for a gold or silver, quartz or placer mine being 50c. and the fee for title being only \$4 plus a few sheets of stamped paper. The only parts of the proceedings which involve any expense at all are the possession proceedings, when the expenses of transportation of the Alcalde or Inspector of Police and his secretary have to be paid. Even the fees of the surveyor are low, and the annual taxes are extremely moderate, being \$1 per year for each claim. The size of a placer claim is 2 by 5 kilometres, and a vein mine consists of three pertenencias.

I have known prospectors to travel and discover good mining property at an expense of \$75 per month, so that when Mr. Maire says "the cost of living is extremely high and traveling costs a small fortune," he is wide of the mark. Of course, if the prospector is of the silk-stocking type and desires an abundance of imported luxuries, he will have to pay accordingly. I do, however, agree with Mr. Maire that Colombia is not a poor man's mining country. Only scientific prospecting and development on a comparatively large scale, say, \$25,000 up, will pay the American who has a higher standard of living than the native, but for the miner with some capital or backing and for the capitalist, Colombia today seems to offer one of the best fields in the world.

P. J. EDER.

New York, November 18.

### The Measure of Precision

The Editor:

Sir—Having much appreciated the sound common-sense paper of F. P. Rolfe, I was very sorry to see the impolite treatment given that gentleman by the *Mining and Scientific Press* in the issue of June 22. Mr. Rolfe's answer in your issue of October 12 again reminds me of the subject.

In making a measurement of width on a lode, one naturally takes it as nearly as it would seem practical, under average conditions, to work it. As Mr. Rolfe says, "lode-widths are usually measured to the nearest inch." As a matter of fact, those who live around mines come to realize that miners never break ground to the nearest inch. It is often impossible to say exactly where the wall or limit of the ore is to two or three inches. The sampler gets into a habit of taking each measurement in about the same way, which will not usually coincide with the way the ore is mined to within an inch or two. In other words, he makes a constant error. In his 'Principles of Mining,' H. C. Hoover puts this constant error at 10% for sampling the average mine by assays. Most mining engineers will agree that the constant error in measuring the width of a vein is more than one inch. Quoting Mr. Rolfe's article, therefore, "it is mathematically incorrect to calculate the average width to anything less than a whole inch." "The writer has not been able to find this principle definitely stated as a law in a mathematical textbook, but it would appear only a matter of common-sense that, in determining the mean of a number

of quantities, the result should be expressed to the same degree of accuracy as that observed in measuring the several quantities." This is true wherever there is a constant error, and while it is true that all measurements should be made, and are made by all practical people, to within the limits of the constant error, Mr. Rolfe's statement will follow.

I venture to suggest, Mr. Editor, that when you were writing you had before you the article by H. S. Munroe, which you published two weeks afterward in your issue of July 6. Now it happens that Mr. Munroe was not talking about the accuracy required in taking measurements, but about the accuracy of a mean of several possible measurements as being representative of the mean of an infinite number of quantities which it would be impossible to measure.

To illustrate the difference, suppose two measurements are made of a lode, one 6 ft. and the other 10 ft. The mean is 8 ft. If each measurement is made to the nearest inch, we may say that the mean of the two quantities is 8 ft. to the nearest inch. It is very improbable, however, that the lode will actually average 8 ft. to the nearest inch when it is mined. Applying the formula you quote, the mean probable error is over 16 inches, which is a very much greater quantity than the one inch which represents the accuracy to which the measurements were taken. It is also more "than the difference between tweedledum and tweedledee."

I think the *Mining and Scientific Press* should realize that some of the best of us are apt to have weak spots in our training, and that therefore we should refrain from using such terms as "nonsensical flapdoodle" when we happen to find some one else's soft spot. I do not refer only to the one article, but I take this opportunity here where the spot really happened to be hard enough to strike fire.

The formulæ quoted by Mr. Munroe and used by Mr. Garthwaite are not applicable to the use to which they put it; that is to say, to the general sampling of a mine. It must be evident that if, by extremely close sampling, the absolute average of the surface exposed in the drifts and raises of a mine were known, it would not be equivalent to the average of the material when mined. As a matter of fact, the subject does not admit of any exact mathematical treatment, but requires the application of ordinary common-sense to the deduction of approximate working methods.

In an article written about ten years ago and republished in T. A. Rickard's 'Sampling and Estimation of Ore in a Mine,' I gave a practical method of determining the mean probable error. It is based on dividing the blocks of ore into parcels, each of which is as compact a figure as possible; that is, not a long thin figure. A square block like that illustrated in Fig. 1 may thus be

FIG. 1.

FIG. 2.

divided into eight right-angle triangles. Then one side only of each triangle is a sampling face.

Suppose now that, in Fig. 2, which is one of the triangular packages, samples are taken at A and B, two points which are near two corners of the triangle. We presume that the average of these two samples represents the face to a little greater degree of accuracy than the average of the whole face would represent the whole tri-

angle. This is a fair common-sense assumption. The mean probable error (according to the formulæ quoted by Mr. Munroe) is given by the deviation of either of the two samples from their mean, multiplied by a constant (which under certain assumptions is 0.6745). We therefore take half the deviation of either of the two samples from their mean to be approximately the mean probable error of sampling the triangle. It is not intended that only two samples should be taken on each triangular face. It is evidently better to take more than two, but the mean probable error must not be thereby decreased, as it would be by the formulæ used by Mr. Munroe. It must still remain the average of all the deviations of the samples from their mean; namely,  $d_1 + d_2 + d_3 + \dots + d_n$

where  $d$  is, as before, the difference between each sample and the average of them all, and  $n$  is the number of samples. The mean probable error thus estimated is not reduced to zero by taking an infinite number of samples along the face, as it is by the formula which you quote.

I am not presuming that the mean probable error is not reduced by taking a number of packages; that is, compact triangles. In fact, my article in 'Sampling and Estimation of Ore in a Mine' was intended to show this as much as anything. When all the triangular packages in a mine have been combined, however, my method shows that there is a much greater probable error than that given by the probability formulæ quoted by Mr. Munroe.

BLAMEY STEVENS.

Temascaltepec, Mexico, October 26.

[Mr. Stevens, like Mr. Rolfe, is apparently led into error by failing to distinguish between the physical operation of measuring the width of a vein, which is subject to a variety of experimental errors, and the mathematical operation of determining the average of a series of measurements, a process which is subject to a rigid and exact analysis. He further compounds this confusion by introducing such factors as the practicable stoping width of a vein, and the error in sampling, which leads to much the same result as though a biologist, in endeavoring to make out the details of muscular structure, were to put a whole quarter of beef in the field of his microscope. Correct conclusions concerning mathematical problems can only be attained by careful analysis of the problem, and can only be clearly expressed by precise use of language.]

Mr. Rolfe's statement, which Mr. Stevens quoted, is a perfectly general one in regard to the average of the mean of several measured quantities, and contains no qualifying statement as to constant, or other, errors. Applying this general statement to the measurement of the width of a vein is to say that the average of a series of measurements of the width no more closely approximates the true width than does a single measurement. With one who does not see the fallacy of such a statement discussion is surely useless, since logic is futile. Such a statement made before a mathematical society would have provoked comment beside which our characterization of it would seem almost Chesterfieldian.

Not improbably, however, both our correspondents are endeavoring to indicate that though the measurements are taken to the nearest inch, they are in reality nowhere near so accurate and it is, therefore, permissible and desirable to express the average only to the same degree of precision as the original measurements apparently possessed. Following a similar line of thought, students in assaying were formerly taught that it is unnecessary to weigh the fluxes used in assaying, since it is necessary, in any case, to estimate the amount required. Generalization concerning such compounding of approximations is impossible. Estimating the quantity of flux required is certainly convenient, and is often safe, especially if the operator is experienced. It is, on the other hand, apt to lead to serious errors at times. Similarly, if the accuracy of measurement of a variable quantity is low, if the number of measurements is too few to give a true average, or if a constant error is involved, then it may be justifiable and desirable to

arbitrarily modify the results obtained by ordinary mathematical processes. This, however, is an experimental detail and is aside from the topic under discussion. To repeat, the measurement of the width of a vein is a physical operation, limited and governed by a great number of experimental conditions. The determination of the average of a series of measurements is a mathematical process, of which the principles are as immutable as the laws of the Medes and Persians. Mr. Rolfe, Mr. Munroe, and ourselves were all discussing the accuracy of the mean of several measurements, if the English language can be taken at its face value. Mr. Stevens is discussing the measurement of the width of a vein. To take up the rest of Mr. Stevens' interesting letter in detail would both require too much space and take us too far afield. Two points, however, require attention. The statement that the average of two measurements, one being 6 ft. and the other 10 ft., and both accurate to the nearest inch, is 8 ft. to the nearest inch, involves the assumption that the vein increases uniformly in width from the 6-ft. point to the 10-ft. point. If no assumption is made as to the vein (which may pinch to less than 1 ft. between these two points), the probable error is a little over 16 in. Finally, in regard to the probable error as computed by Mr. Stevens, it surely must be unnecessary to point out the error of his statement that  $\frac{d_1 + d_2 + d_3 + \dots + d_n}{n}$  does not have a

value of zero when  $n$  becomes infinitely great.—EDITOR.]

### California Miners' Opportunities at the Panama-Pacific Exposition

The Editor:

Sir—Probably the most important business which the California Miners' Association will transact during its convention in San Francisco, December 9 to 12, will be the serious consideration of tentative plans relating to the scope and character of California's exhibit of mining and metallurgy at the Panama-Pacific Exposition. It will lie largely with this representative body of practical men whose technical knowledge and wide experience have made these industries all that they are today to urge the early initiation of the work that must be done before 1915 in making California's exhibit of its mineral wealth a worthy representation of the progress of the Golden State. Many members of this Association have expressed themselves to me as strongly favoring the adoption of a definite policy on the part of the California Miners to coöperate with the Exposition authorities in making the mining and metallurgical exhibit of this state unique and the most comprehensive of its kind in the history of world's fairs. There is no reason why this ambitious program should not be accomplished.

We've got the men,

We've got the mines,

We've got the money, too. . .

The experience of Frederick J. V. Skiff, director-in-chief of the Panama-Pacific Exposition, as the director of the exhibit of mines and metallurgy at the Columbian Exposition, and as director of exhibits at the St. Louis Fair, has specially fitted him to supervise the planning and installation of such a display as the California mining industry deserves.

A golden opportunity presents itself to the mining men of this state to show to the world how wide is the range of its mineral wealth, and how rich are the rewards of those who exploit its resources. Beyond all doubt the California mining exhibit could be made one of the star attractions of the Exposition. The whole world associates the very name of California with that alluring word, gold. Every visitor will be drawn by every instinct of curiosity and every impulse of sentiment to see what California will have to show the world in its display of the historic features and the technical and economic progress of its most famous industry. Our guests will not be satisfied with a hurried lodge-podge of ore and machinery, all too obviously advertising the private interests of favored firms or corporations. They will expect to see a faithful repro-

duction of the development of mining and metallurgical methods from the days of '49 to the dredges and stamp-mills of 1915. In its entirety, the impression of the immense mineral wealth of this state must be as inspiring a spectacle as the panorama of the Panama canal itself. In fact, even this colossal enterprise does not represent a much greater excavation of rock and earth than has been dug and blasted and hydraulicked from the flanks of our Sierra Nevada. Well may the miners of California boast of the proud fact that the pioneers and their successors have produced enough gold to pay five-fold the cost of constructing the Panama canal. It is fitting that an area be reserved commensurate with the achievements of California miners, not only in regard to their services to the state and nation, but to the world.

Because of the exigencies of spaces, California's exhibits have heretofore occupied a more restricted area than will be necessary at our great fair. Its display at the Louisiana Purchase Exposition at St. Louis in 1904 covered a space of 43 by 103 ft. But between Harbor View and Golden Gate park there will be no excuse for crowding. California miners have now the opportunity to reserve a piece of ground of sufficient size to do some justice to the wonderful mining possibilities and realities of this state. Indeed, there are many good reasons why California's mining exhibition should be shown to be in every sense in a class by itself. A separate building constructed upon the Spanish mission plan with spacious patios would be most attractive in its exterior and interior. California granite, marble, sandstone, slate, terra-cotta, brick, and other building materials should compose its structure. Perhaps its steel frame could be put together with every girder and every bolt the product of California iron ores. Within its walls ores, oils, and other mineral products would be displayed. Models would show the operations of mining and metallurgical work. Photographs and moving-pictures should give a vivid portrayal of the different phases of the mining industry from its early stages to the present time. There will be unlimited opportunities for the mining counties of California to vie with one another in the presentation of interesting films depicting the discovery and development of their mineral deposits. Then there may be most effective ways of arranging arrastres, rockers, long-toms, Mexican ladders, and other primitive appliances so as to contrast strikingly with the improvements of today.

But one roof cannot house the ensemble of California's display. The long and rainless summer season at San Francisco will permit open-air features such as have never been possible elsewhere. This favorable condition will enable us to present a most graphic representation of the mineral resources of California and their exploitation. It will be necessary and practicable to select a site, preferably upon a steep slope, where the various mining ventures so successfully operated in California may be arrayed, *en echelon*, one feature rising above the other.

The whole plan might be a reproduction of a cross-section of the Sierra Nevada, contiguous to the Mother Lode. On a flat space in the foreground a modern dredge could be shown at work. Above it would lie two low foothills, between the contour of which might appear placer-mining scenes. Prospectors, either in the flesh or in the form of wax dummies, could be seen at work with pick, shovel, and pan. Periodically they would strike 'pay-dirt.' Then the varied conditions of gravel-mining should be reproduced in their logical succession. Rockers, sluice-boxes, wheelbarrows, buckets, and windlasses would be followed by hydraulic mining on a more or less comprehensive scale. Old river channels would then be revealed on the ridges, and there drift-mining would be duplicated. All the dynamic geology of the erosion of auriferous strata and the concentration of 'pay-streaks' in the beds of ancient and modern streams could be shown at low cost.

Elsewhere a miniature of the Mother Lode might appear. Silhouetted conspicuously against the sky-line would stand the 'gallows-frames' where hoists would lift skips laden with quartz apparently from the depths of the earth. The familiar adits and shafts could be made as natural

as in real life. Mules and men and Lilliputian locomotives would emerge from the mouths of adits drawing tram-cars laden with ore. The methods of shaft-sinking, stoping, mine-timbering, drilling by single or double hand, as well as by modern machines, should all be shown. Systems of supplying pure air to miners and the newer arrangements for promoting their safety should also be represented. In the background above this section of the Mother Lode a panorama effect of the High Sierra should tower. These snowy peaks would indicate the inexhaustible wealth of water and power representing the power of millions of horses waiting to be harnessed.

Another terrace could show the course of the canyon of the Sacramento through the famous copper belt of Shasta county, with the great white dome of Shasta looming majestically over the scene. There the copper ores could be shown on the successive stages of their journey from the mine to pure metal. Smelting plants would produce matte and blister copper, while electrolytic refineries would turn out salmon-red cathodes and ingots. Other features of mining work could be shown in a highly instructive manner. Steam-shovels burrowing busily, aerial tramways transporting ore across canyons, hydraulic elevators rattling away with their floods of muddy water and gravel, belt conveyors, and other ingenious labor-saving devices in vogue in California could be shown in operation.

#### METALLURGICAL METHODS

The plan of the terrace effects would be particularly advantageous in arranging the metallurgical exhibits of California, as it would be convenient to bring the ores by gravity to the mills and reduction works. As the gold-bearing quartz is trammed or hoisted from the levels of the model mine it should be conveyed to the grizzlies and rock-crushers in sufficient quantities to keep a 5-stamp mill running throughout the Exposition. Visitors could be given a vivid impression of the way the gold is won from the rock by watching the automatic feeders shake the crushed ore down into the mortars where the dropping stamps would crush it to pulp. The process of amalgamation upon the silvered plates would be interesting, while the clean-up and retorting of the cheesy balls of amalgam would be fascinating. Then the motions of the concentrators and the various styles of vanners would exhibit another phase of the recovery of gold and silver. The roasting and chlorination of sulphides would follow in the natural order. Tailing would be transferred to a series of cyanide vats, where the leaching and newer agitation methods would be shown, together with the ultimate precipitation of the gold in the zinc-boxes, or by its recovery by electro-deposition.

Other metallurgical methods employed in California would be interesting. The smelting of ores will be most instructive. As an unique feature of metallurgical work in this state, it will be especially desirable for the Government to coöperate with the California Miners by giving an exhibition of its up-to-date electrolytic bullion refinery now being operated in the San Francisco Mint. A number of prominent mining men believe that at least a thousand tons of auriferous quartz could be run through a mill at the fair, the proceeds of the clean-ups covering the expenses of operation. The mining of other minerals and the refining of their products would illustrate the wide range of the mineral industry in California. Crude borax could be hauled from a miniature Death Valley and purified. Salt and the recovery of alkaline compounds would likewise be all part of California's great show. Of economic importance second only to gold, would be the oil exhibit. Models would show the occurrence of oil in porous strata, the methods of drilling for it, and the derricks. Illustrations of gushers will tell the story of many millions of dollars a year derived from this source. Then the storage of petroleum, its transportation by cars and pipe-lines, and its final distillation and separation at the refineries, in so far as the details may be made public by the refining companies, would be a valuable feature of California's mineral exhibit.

#### ECONOMIC IMPORTANCE OF THE EXHIBIT

The men who will be chosen to plan and install California's great mining exhibit must not only be practical miners and metallurgists, but they should possess powers of imagination which will enable them to exercise artistic taste and to evince a sense of the esthetic in evolving the details of this display. No mining district in all the world has had so romantic a history. Its retrospect should inspire California Miners to make the most of their opportunities to set forth the daring deeds of the Argonauts, and the achievements of the two generations that have kept up their good work.

When one considers the cost of making so elaborate a display, the transient nature of its glory is an apparent factor. Great as is its educational value, all will agree that practical results must be later accomplished. The fundamental purpose of exhibiting the multifarious phases of the mining and metallurgical industry of California is to promote the material welfare of the state. Each exhibit should represent most clearly just what is being done by our miners, and what may be accomplished by those who will follow their example by investigating the rich mineral resources within our borders. With each stage of mining operations there should be shown certified cost-sheets, giving in detail the expense of taking rock out of the ground and of extracting its content of the various metals and products. Each stage from stoping ore to stamping bullion, together with overhead and incidental charges, should be shown on the debit side. To the credit of the mines would appear the receipts from the bullion and mineral products sold. Thus each exhibit of the mining, metallurgical, and oil industries would have a more practical interest to the visitor by showing the economics of their operation on a commercial scale.

All mining men who saw the California mining exhibit at the Midwinter Fair in San Francisco in 1894 will recall the lasting impression it made upon all who beheld its many interesting features. Although we do not regard our little local fair as in the class of the Columbian or Louisiana Purchase Expositions, there was much merit in this endeavor of energetic and public-spirited Californians. How much this exhibit of mining and metallurgical activities of nearly nineteen years ago really helped these industries it is impossible to estimate. But all mining men who have with broader vision watched the remarkable development of the mineral wealth of this state since then now fully realize that the cost of this exhibition in the Midwinter Fair was returned many times over in the influx of capital which followed. Today there are vast riches in the mineral districts of California awaiting the investment of capital which will surely be attracted to this state if the demonstration of the results being obtained by our producing mines are properly displayed by capable men.

HAROLD FRENCH.

Berkeley, California, November 27.

PLACER mining has been carried on continuously in the Bonnichfield region of Alaska since 1903, and although the production of gold there has never been large, the output has been steady. The inaccessibility of the region and the high cost of transporting supplies to it have prevented the mining of any but the richest ground, but if the proposed Government railroad to the interior by way of Susitna and Nenana valleys should be built, the mining industry would be greatly stimulated. A schist belt, similar to that in which most of the Alaska gold districts occur, crosses the Bonnichfield region, so that the geologic conditions are favorable for the discovery of additional gold-placer areas. Veins containing iron sulphide and some gold have also been found, and although these are not now being mined, it is possible that the region may some time support a considerable lode-mining industry.

NITRATE production in Chile for the year ended June 30 amounted to 2,469,000 tons, of which Europe took 1,711,000, United States 503,000, Great Britain 132,000, and all other countries 114,000.

## Special Correspondence

### BLACK HILLS, SOUTH DAKOTA

REPORT OF MINE INSPECTOR.—DIVIDENDS PAID.—GOLDEN  
REWARD ROASTING PLANT.

The annual report of R. L. Daugherty, State Mine Inspector, covering the fiscal year ended October 31, has just been issued, and shows the mining industry of the Black Hills to be in a highly prosperous condition. The gold production is greater than ever before, and the accidental deaths are only one-half of the smallest number previously reported. With 3000 men at work underground in the Black Hills, there were during the year but 3 deaths from accidents. The report gives the following statistics of production (except the average per ton, which I have calculated):

Name of producer.		Production.	Av. per ton.	Employees.
Homestake .....	1,529,474	\$6,596,000	\$4.312	2600
Golden Reward .....	52,583	323,847	6.158	133
Wasp No. 2 .....	158,840	308,596	1.942	100
Mogul .....	59,384	242,568	4.085	86
Trojan .....	62,061	.....	.....	111
Lundberg, Dorr & Wilson .....	21,264	77,497	3.644	14
New Reliance .....	12,984	34,268	2.639	32
Victoria .....	3,347	14,672	4.382	32
Deadwood Standard .....	3,500	9,382	2.680	28
*Smaller companies and individual shippers.....	22,236	416,969	.....	642
Placer mining (estimated) .....	.....	11,800	.....	30
Totals .....	1,925,673	\$8,035,599	\$4.166†	3808

\*This includes the bullion production of the Trojan, but does not include the employees and tonnage of that company.

†Average.

The Homestake paid \$1,310,400 in dividends during the year and the Wasp No. 2 \$85,000. Operations by close corporations such as the Trojan, Richmond Operating Co., and Golden Reward, together with Lundberg, Dorr & Wilson, lessees, and individual mine-owners bring the profits of the year to over \$1,500,000.

The Homestake operated continuously throughout the year. The most important work was the completion of the Spearfish hydro-electric plant. This, with the Englewood plant, gives the company a total of 5450 hp. There was being used, on October 31, 2850 hp., and the work of changing to electric power about the plant is still in progress. The average stamp-duty at the Homestake for the year was 4.182 tons per stamp per day, for the 1000 stamps for the 366 days of the year, not calculating lost time, which is almost negligible. The Wasp No. 2 makes a big record, when the value of the ore is considered. The Golden Reward is doing important work in erecting a roasting plant. It is the first company of recent years to attempt the roasting of the blue and sulphide ores of the Bald Mountain district as a preliminary to cyaniding. The operation of the plant will be watched with much interest, as its success will mean much to the miners of that district, where there are large quantities of good-grade milling ore that cannot be treated by the methods in use at present.

Among the group of smaller producers mentioned, New Reliance, Victoria, and Deadwood Standard operated only a portion of the year. Lundberg, Dorr & Wilson treated large quantities of custom ore, mainly from the Mogul, after the burning of that company's mill in March last. The figures given represent ores from the Big Bonanza and Buxton mines. Placer-mining shows a small output, and it appears that the dredge at Mystic has not operated with much success. Aside from the precious metal production, the report mentions the sandstone quarries at Hot Springs, which during the year turned out \$80,000 of building material, and the United States Gypsum Co., at Rapid City, which operated seven months and produced \$31,000 of gypsum products, including stucco and building tile.

### BUTTE, MONTANA

LEACHING PROCESSES.—A NEW COMPANY.—ELECTRIFICATION OF RAILROADS.

The much-heralded leaching treatment of chrysocolla in the granite at Butte is likely to prove anything but perfectly plain sailing. In the first place, it has been generally held that chrysocolla is not easily soluble in sulphuric acid solutions of the strength usually considered permissible in leaching practice. Then again, there are iron and calcium minerals in the gangue of the silicate ores which are probably equally as soluble as the copper and which will tend to foul the solutions and probably cause other troubles. But assuming that the copper has been satisfactorily secured in solution as copper sulphate, it is next proposed to precipitate the copper by electrolysis. That this is a possibility is, of course, well known, and that it is done commercially in the electrolytic refining of copper is equally

well known. But that it can be carried out profitably on the dilute solutions derived by leaching methods has been heretofore considered impracticable by electro-metallurgists. The stumbling-block, of course, is the resistance of the dilute solutions. It is considered poor practice in an electrolytic copper refinery to permit the copper sulphate solutions to fall below 15%, or the sulphuric acid solution to fall below 6%. When the solutions become weaker than this, the current consumption increases unduly. Some recent experimenters claim to have overcome the various difficulties, and it may be that they will be overcome in practice. However, it is well to call attention to some of the difficulties, in view of the fact that a popular impression is gaining ground that the general methods to be employed are new and especially applicable to the chrysocolla at Butte.

A. B. Wolvin, president of the Butte & Superior Copper Mining Co., has organized the Butte-Duluth Mining Co. to take over the Montgomery, Macarona, and portions of the Altoona, Amazon, and Colleen Bawn mining claims. The property lies east of the East Butte mine and adjoins the claims of the Bullwhacker Copper Co. The ground is believed to contain large bodies of silicious copper ore, which it is proposed to mine by means of steam-shovels. Stripping of the slight overburden is now in progress preparatory to beginning work with the shovel. It is proposed to ship the high-grade ore direct to smelters, but the low-grade ore will be leached on the property. A 500-ton leaching plant is planned, and the construction of the first unit of 100 tons is under way.

Several of the small, irregular producers of the Butte district have sunk shafts to surprising depths, in view of the showings. The Davis-Daly, Raven, Tuolumne, and Butte-Alex Scott companies all have shafts in the neighborhood of 2000 ft. deep, but there is comparatively slight production to show for all this work. So that the popular cry for depth seems, after all, not to be the panacea for every failure to produce profits.

The proposed hydro-electric power companies' consolidation, discussed in a recent letter, is probably a preliminary step in the long-talked-of electrification of the transconti-

mental railways in their steep hauls over the mountains. The Butte, Anaconda & Pacific railway expects to use 8000 hp. for its line between Butte and Anaconda, and it is now announced that the Chicago, Milwaukee & Puget Sound railway is considering the electrification of its line over the Continental divide, and possibly also the Belt mountains divide and the Coeur d'Alene mountains divide. From 16,000 to 20,000 hp. would be required for these purposes. If the railways begin using electric power, Montana water-power will be rapidly developed and utilized.

### JOPLIN, MISSOURI

NEW MILLS AT MIAMI.—FEDERAL LEAD CO. ENTERS DISTRICT.—NEW FIELD IN OKLAHOMA.

At Miami, Oklahoma, four mills are being built. They are the Mizpah, the Cactus, the Chapman & Lennan, and the Prairie. Within a week or two work is to start on the Carson & Dodson mill. Each of these plants has a capacity of 250 tons; they are modern in design and should add greatly to the output of concentrate from the district. Gas-engines are used in each mill, and air-compressors are employed for operating the drills. New development down to 324 ft. shows ore, a slanting zone having been reached which is touched at comparatively shallow levels in the eastern part of the district but which dips steeply to the west. Because of the heavy volume of water in the lower ground pumping operations have lowered the water only to the 224-ft. level. In the deep workings lead ore is especially abundant, often equaling the average zincblende in alluvial. Any one of these mills in the ordinary district would show a capacity of 350 tons, but due to the complex character of the Miami ores more careful milling is necessary. The initial grinding is to  $\frac{3}{8}$  in. instead of  $\frac{1}{2}$  in. as is the practice in other districts.

Development on an extensive scale has been started by the Federal Lead Co., one of the largest lead-mining concerns in the Flat River district of eastern Missouri. The advent of this big company in southwestern Missouri means much to the Joplin district. Following an extensive drilling campaign southwest of Prosperity, shaft-sinking has started. Thin sheet ore, 2½% zincblende and 1% lead, has been found. It is similar to the sheet ore of the other big mines of that district. The Federal company has also found a deeper run of ore, at 230 ft., on the old Troup farm, south of Webb City, and shafts will be sunk. Former development on this land, which resulted in a heavy output of ore, was conducted at much shallower levels.

A separate plant for the treatment of sand and slime is being constructed at the Coahuila Mining Co. property at Duenweg, and all the old tables will be removed and replaced by new tables in the new plant. The new plant is of steel and concrete, and contains eight sludge tables in addition to the classifiers, settling-tanks, and other machinery necessary to treat the ore in the best manner. Recovery of the fine is growing to be recognized as an important factor in local milling practice.

Northwest of Lincolnville, Oklahoma, a new zinc and lead field is being opened. The nearest mines are those of the north Miami field, 2½ miles to the south. Prospecting with churn-drills has been going on in this isolated region for a number of months, but little news of the important discoveries that have been made has leaked out. Following strikes in several drill-holes, a number of shafts are being sunk. The region lies in a rolling prairie country that is celebrated because of its luxuriant crops of timothy hay. Shafts are now being sunk by J. O. Goodwin and J. M. Cooper, of Baxter Springs, Kansas; Ward and McReur, of Kansas City and King Springs, Missouri; Beck & Co., of Joplin; Price & Co., of Joplin; Mark Hall, of Joplin; E. H. Evans, of Onawa, Iowa; George Meece and William Waugh, of Joplin; and a number of other companies. Zinc and lead ores, sometimes occurring in rich pockets, but more often found in thin disseminated ground, are found at a depth of 155

ft., continuing down to 165 ft. and sometimes reaching to 185 feet.

A siphon system of draining the drifts of the Chapman & Lennan mine at Galena, Kansas, is interesting in that it has reduced pumping expense to a minimum. There is, in fact, no expense in keeping the siphon system in operation. The siphon is in the workings of the old Prudential land, recently taken over by Chapman & Lennan. A big area of old ground has been developed, but does not drain to the pump-shaft owing to intervening ridges of ground, representing the barren streaks in the old ore pockets. Formerly a 10-hp. motor was employed to lift the water over one of these intervening walls, and this necessitated a big expense. Since the laying of a 2-in. siphon pipe the motor has been taken out. The pipe was laid from the water-filled drift over the obstruction and with a 20-ft. fall there was suction enough to keep the water going after the pipes were once full and the stream started.

### SALT LAKE CITY, UTAH

ACTIVITY AT ALTA.—WALL ROLLS DISCARDED.—FUTURE OF SOUTH UTAH.

Alta is the scene of increased activity, despite the fact that winter always finds it snowbound. The most important event has been the announcement of an extensive campaign of deep development by the Michigan-Utah. This company, which is a consolidation of several properties, has developed several good bodies of ore above the level of the Solitude adit, which reaches about 800 ft. under the mountain, but the consensus of opinion of several engineers who have been making thorough examinations is that deep development is the proper policy, especially with a view to finding a continuation of the old Emma ore-zone. The company has ample funds for a thorough campaign. The \$200,000 bond issue has been paid off, and money for exhaustive work has been provided by new interests which have entered the company, headed by the Boston firm of Hornblower & Weeks. At the same time negotiations are in progress looking toward a consolidation of the Flagstaff, Columbus, and Columbus Extension properties to drive a long adit to drain and develop these mines at depth. One of the greatest handicaps of the district for years has been the heavy flow of water, which has prevented deep development until consolidation and strong financing made long drainage adits possible.

D. C. Jackling, president of the Utah Copper Co., announces that the property is again producing the normal amount of ore for the first time since the strike was declared. The mine is sending out 20,000 tons per day, which is the highest point ever reached. The other mines are in operation, but they have not yet fully reached normal. The Utah Copper, which employs largely unskilled labor, has found it easier to get men than the underground mines, which must recruit their forces with skilled miners. Steady progress is being made, however, although it may be some time before all the mines have full crews. Following the visit of Martin Miles, of London, representing English stockholders, the New Utah-Bingham is resuming work. The company has been reorganized and funds provided for further development. Ohio Copper has abandoned the Wall rolls and will replace them with other crushing machinery. The company has increased its production to between 1800 and 2000 tons per day and is planning to enlarge the mill to handle 3000 tons. The Utah Metal Mining Co. has not resumed operations since the strike, but the announcement is made that it will start soon, and that the long bore will be completed some time next spring. There is still about 1300 ft. of work to be done to complete the task of running under the mountain from the Bingham to the Tooele side, and provide means of transportation to the Tooele smelter, as well as facilities for deep development of many of the Bingham mines.

The International Smelting & Refining Co. has not yet resumed operations in the copper smelter, closed as a result of the Bingham strike, but has two of its lead stacks operating steadily. It is stated that the other two

stacks will be ready in January, and that ore is available to keep them all going. Local shareholders are debating seriously over the future of South Utah, which has just issued a report showing a net loss for the year ended June 30, 1912, amounting to \$31,114. This is the old Cactus mine, reorganized as the Newhouse Mines & Smelters Corporation, and again reorganized as the South Utah. Salt Lake people bought heavily of Newhouse stock on 'inside' information when the shares were quoted around their highest point, and many of them have stuck with it in the hope that a profitable mine would yet be developed. The report shows that the ore contains 1 to 1.6% copper, but is so scattered and the difficulties in milling are so great that the cost of producing copper reached 15½¢. per pound. The company secured an average price of 13.45¢. per pound. The optimistic hope that high copper prices may enable the company to keep going and possibly develop new orebodies. Meanwhile, plans are being made to use a portion of the mill to treat the lead-zinc ores from the neighboring Horn Silver mine. Another mine which is confessedly on the ragged edge, but which is showing surprising vitality, is the old Consolidated Mercur. The annual report shows net operating earnings of \$10,797, with dead work done amounting to \$17,498. The company will keep on work, continually looking for new ore, so long as it can break even.

### JOHANNESBURG, TRANSVAAL

OPTIMISM IN RAND JOURNALISM.—WHAT THE MINES SHOW.

The articles by T. A. Rickard, 'Persistence of Ore in Depth,' appearing in the *Mining and Scientific Press* August 24 and August 31, have attracted some attention here, more particularly where the East Rand Proprietary property comes in for attention. The local technical journal does not seem pleased with being charged with avoiding giving publicity to Mr. Hellmann's testimony as to the impoverishment of the Rand blanket ores in depth, but perhaps your contributor does not know that, apart from the policy of the local technical journal being not to decry the Rand or draw attention to its shortcomings, its aim is rather to please the mining groups and one group in particular, than circulate the whole truth about local mining affairs. Every paper of any influence on the Rand is expected to pursue the same course; the local mining journal is not the only one pursuing this policy, and therefore is to be equally blamed with the rest, the only explanation being, perhaps, that "needs must where the devil drives."

There are, however, when all is said and done, few mining fields in the world where the veins are so persistent in depth as on the Rand. What makes their persistence perhaps most remarkable is the fact that they are conglomerates, naturally the most uncertain of any of the sedimentary rocks. That these conglomerate reefs maintain their value in depth is, however, quite another matter; the bulk of the reliable evidence available on the Rand being that gold content has declined in depth. It is scarcely correct to say that in every case the gold content has decreased, but there are certainly six reliable decreases to one reliable improvement.

Starting on the Western Rand, no mine, perhaps, has suffered through falling grade as much as Randfontein Estates. The Champ d'Or outcrop mine always was a profitable one, while its deep-level relation is closed down because it was unprofitable. The same, but less striking, state of affairs exists between Vogelstruis Estate and Vogelstruis Deeps, but the conditions are reversed at the Main Reef West, which recovers 31s. per ton as compared with 27s. for its neighbors at the outcrop, the Aurora West and New Unified mines. The next reliable instance may be found in that the Robinson and Ferreira mines recover 40s. per ton, while the Robinson Deep has to be satisfied with 32s. per ton. The Village Main also recovers about 40s. per ton, while its neighbor to the dip obtains but 30s. per ton.

Much has been said about the City Deep being an exception to the rule, for here the recovery averages 36s.

6d. as against an average of 32s. 5d. among its four outcrop neighbors. But in every other instance going east, the gold recovery has consistently decreased with depth, the present recovery of 28s. 6d. per ton at the Geldenhuys Deep being represented by 21s. 6d., the average recovery of the Jupiter mine, now the deepest gold mine in the world. Then comes Simmer & Jack with 22s. 9d. per ton recovery, as compared with 16s. 10d. for the Simmer Deep; while if the gold recovered at Brakpan, 32s. 6d. per ton, is compared with that at Benoni, New Kleinfontein, and New Modderfontein, 34s. per ton, it will be seen that even the celebrated Brakpan mine barely holds its own with the average of the outcrop mines in the matter of the grade of ore sent to the mill. It will therefore be seen that out of twelve reliable instances extending over a length of fifty miles on the Rand, only two instances of an improved yield in depth can be quoted, and in these instances the improvement is about a pennyweight per ton. It is, of course, impossible to predict at what depths mining on the Rand will become unprofitable, since as much depends upon working costs as upon gold content; but the Simmer Deep, with a gold recovery of 16s. 10d. per ton and working cost of 15s. 9d., although fully developed and in full swing, has not succeeded in paying a

FILTER PLANT, CROWN MINES.

dividend. A similar state of affairs exists at the Jupiter mine, with a gold recovery of 21s. 6d. and working cost of 19s. 9d. But these two mines are situated in notoriously low-grade areas and afford no indication of the depth at which the other mines may be placed in a similar position.

### BOSTON

DOW TROUBLES.—NEVADA-DOUGLAS DIVIDEND.—LAWSON AT IT AGAIN.

The aftermath of the Dow troubles is being looked after by degrees in Boston, and it is apparent that every effort will be made to have the companies formerly sponsored by Dow placed on a clean, strong basis. Notices have been mailed to stockholders of the Franklin Mining Co. advising them of a special meeting called for December 18, to take action regarding litigation to be instituted against the former directors arising out of the Dow trouble. The directors have decided, in order to forestall criticism, to have proxies to the meetings run to others than themselves. Accordingly, proxies accompanying the notices run to Herbert M. Leland and Harry M. Stonemetz, members of Stock Exchange firms. Franklin is the only one of the so-called Dow properties which is on a producing basis, and it is believed in Boston that if the difficulties in which Mr. Dow left it can be tidied over, it will give a good account of itself.

Stockholders of the Nevada-Douglas Copper Co., at Yerington, have received notice of a dividend declaration of 12½¢. per share by the directors, payable February 1, books closing January 10. This is the first dividend to come from the Yerington, or Mason, district, but will be

followed by one from the Mason Valley Mining Co. in March. The Mason Valley dividend will probably be 50c. per share and will be designated as a quarterly payment. It is not understood that the Nevada-Douglas directors have committed themselves to a quarterly dividend as yet, though stockholders are hoping the company will be able to pay dividends of at least 50c. per year, since \$1 per year was freely predicted on copper selling at a lower figure than at present during the promotion period. The Nevada-Douglas dividend declaration was apparently disappointing, as the stock sold off freely immediately following the announcement. With all stock outstanding, the 12½c. dividend calls for a distribution of \$125,000. A. J. Orem, the president, reports that the large floating indebtedness which the company had at the beginning of the year has been paid, current expenses met, and money is now accumulating in the treasury. Nevada-Douglas enjoys the unique distinction of having been promoted independently in Boston in the face of the hostility of the Stock Exchange and its official organ.

The present copper movement seems to be so strong that it is even reviving the dead 'wild-cats.' Recently it has been noticed that stock of the Iron Cap Copper Co., of Globe, is very scarce, owing to improved conditions at the property. Recent developments at the Superior & Boston are also helping the Iron Cap. This company will be recognized as the reorganized National Mining Exploration Co., which formerly enjoyed an active market on the Curb and which secured a loan of \$100,000 from N. L. Amster some time previous to Mr. Amster's financial difficulties. The National Mining Exploration, now the Iron Cap, adjoins the Arizona Commercial, and it was thought at one time when Arizona Commercial was itself active and strong, that the smaller company would eventually be absorbed by it. Both companies fell on evil days and had to be re-organized, and National Mining Exploration was largely forgotten by traders.

Stockholders of the Bay State Gas Co., which was taken over by Thos. Lawson for the purpose of raising working capital to 'play the market,' will doubtless be glad to hear of Lawson's winnings, as there are nearly 4,000,000 shares of Bay State Gas outstanding, belonging, it is said, to nearly 100,000 people. The sum of \$100,000 divided among 4,000,000 shares would mean a dividend of 2½c. per share, or about 10% on the present selling price of Lawson's much touted Bay State Gas or National Stock. On Tuesday November 19, the annual stockholders' meeting of the Bay State Gas Co. was held in Wilmington, Delaware, and the usual Lawson method of holding an annual meeting was gone through with. Lawson himself failed to appear on the scene, as was the case in the Trinity and First National meetings, but sent a representative. In the Bay State Gas meeting his secretary, Mr. McSweeney, represented him. As usual, a brief statement was made vicariously from Lawson and a good deal was said about the exceptional charter which the Bay State Gas Co. holds, this seemingly being the principal and most cherished asset of the company. It was stated that the funds of the company's treasury had been used for speculative purposes. It was admitted that the Government had investigated the company, but had finally given it a clean bill of health. When Mr. McSweeney was asked if Lawson's advertising bills were being paid out of the Bay State Gas treasury funds, he replied in the negative, saying "this was all Mr. Lawson's personal matter."

### MELBOURNE, AUSTRALIA

ANOTHER VICTORIAN 'HOPE'.—AN AUSTRALIAN ALASKA GOLD MINES.—LOW WORKING COST.

In Victoria the chief excitement in the mining world during the past three or four weeks has been in connection with a development in the old and long-neglected Beaufort field. In the 50s when gold rushes were more plentiful than strawberries, its alluvial richness attracted a large number of diggers, many of whom made large fortunes. But, its surface wealth exhausted, the district was

suffered to sink into the sleepy sadness characteristic of the abandoned mining field, and so it remained until recently a syndicate was formed to endeavor to find a deep channel. Some twenty drill-holes were put down, and eventually a shaft was sunk, which at a depth of 117 ft. was still in wash. As, however, the existence of a deep channel had been demonstrated by drilling, sinking was continued to a depth of 182 ft., and a drift was driven at 175 ft. This drift is now in 235 ft. in workable ground. Several drifts at different levels have developed a block of ground 350 ft. long and 200 ft. wide, from which 164 fathoms of gravel has been taken out, yielding 548 oz. of gold, the gravel treated having ranged in value from 2 to 12 oz. gold per fathom. The width of the channel is not yet determined. This property is known as the Hope. Adjoining it on the west is the West Hope, which has also found, by means of drilling, an auriferous channel, presumably an extension of that in the Hope. The prospects of the Hope and of at least two or three neighboring properties are distinctly favorable. There is no indication of trouble from water, firewood is abundant, and is obtainable delivered at 66c. per ton. It is estimated that a yield of a little over ½ oz. per fathom will clear all expenses, so that, if the average yield of 3½ oz. be maintained, there will be an ample margin of profit.

If Victoria has a promising little discovery in an old and long-deserted field, New South Wales has a still more promising one that cannot by any manner of reasoning be described as small. It is also in an area that has been worked for many years, but its delayed development has not been due, as in the case of the Victoria district, to its surface riches being worked out, but to the fact that it has never received fair treatment, having always been worked upon an inadequate scale. The scene of this new-old discovery is Yalwal, some 18 miles west of Nowra, the southern terminus of what is known as the South Coast line, a railway running almost due south from Sydney along the coast. The original discovery was made in 1871, but from then until quite recently it never had a show. It is essentially a large low-grade orebody that requires to be worked upon a tremendous scale, but its occasional enriched areas have simply been picked at here and there on the surface.

The gold occurs mainly as an impregnation in quartzites, slate, and conglomerates, and it is waste of time to attempt to mine the small intersecting quartz veins; the whole material must be extracted and treated if the work is to be done at a profit. That is what the Yalwal Exploration Syndicate, for whom Ernest W. Spencer, formerly general manager for the Consolidated Gold Mines of New Zealand, has been sampling, surveying, and appraising the field for the past 16 months, is preparing to do. The auriferous zone has hitherto been limited to an area ¾ mile long and ¼ mile wide, being bounded by granite and dolerite. The gold-bearing belt is divided into two parts by a gully, on one side of which the sulphide zone is reached within 70 ft. of the surface, while on the other the oxidation indicates a depth of at least 200 feet.

Costs are not expected to exceed \$1.50 per ton, including the treatment of slime, and Mr. Spencer expects to reduce them to \$1.20 when a plant for the treatment of from 500 to 700 tons per day has been constructed. In fact, I understand that Mr. Spencer, though with a natural caution he announces that he expects the costs not to work out ultimately at more than \$1.20, really anticipates that they will be reduced to considerably less than \$1. If so the expected gross content of \$2.20 per ton will yield a handsome profit. The latest bulk test of 1300 tons gave by amalgamation and cyanidation about \$5.55 per ton with 200 tons of the richer sands still in the vats. The slime is said to contain 40% of the gold, and has not hitherto been treated in any way. Assays show the slime to be quite as rich as the sand. Apparently the vein here is a very big thing; the biggest Australia has had occasion to welcome for many a long day. It is to be hoped that it will come up to expectations.

## General Mining News

### ALASKA

#### JUNEAU

During October the Alaska Mexican 120-stamp mill worked 30.72 days and crushed 19,740 tons of ore, producing \$23,326 in free gold and \$25,258 from 408 tons of concentrate. The realizable value was \$48,584, and net profit \$18,959. The average per ton milled was \$2.46. Development covered 406 ft., and the stock of broken ore increased 3975 tons.

The Alaska United Ready Bullion and 700-Ft. Claim mills worked 30.48 and 30.60 days, crushing 18,704 and 19,677 tons, respectively, yielding free gold worth \$59,302 and \$54,514 from 966 tons of concentrate, the total realizable value being \$112,677 and net profit \$62,018. Development covered 326 and 128 ft., while the stock of broken ore increased 2468 and decreased 1204 tons, respectively.

#### NOME

Nome will have a greater winter population this year than before. The number of people entering the district for the year to date is 1605, and the number leaving is 1287. Several parties will operate on the beaches and dumps during the winter. About 25 men will remain around Taylor creek and several will take out winter dumps in the Kougarok district.

### ARIZONA

#### COCHISE COUNTY

A 400-ton smelter, costing about \$400,000, is to be built at Douglas for the Shattuck & Arizona mine. Shares of the latter have recently advanced, caused by persistent rumors of a consolidation with Calumet & Arizona which appear to have no foundation.

#### GILA COUNTY

The Gibson continues to make regular shipments of ore to the smelter, and may soon increase its working force. The Castle Dome, six miles west of Miami, is attracting attention. The rock here is mainly granitic, as distinguished from the schist formation of Miami, Inspiration, Live Oak, and other properties. At the South Live Oak drill-hole No. 4 is down 765 ft. in schist. Much caving has hampered drilling operations. At 1246 ft. the Southwestern Miami stopped drilling No. 8 hole. Development at the Superior & Boston has been encouraging of late.

#### GRAHAM COUNTY

During the year ended August 31 the Shannon Copper Co. produced 16,406,336 lb. of copper, 2615 oz. of gold, and 170,695 oz. of silver, worth \$2,594,866. Operating costs were \$1,678,737; freight, refining, etc., \$231,900, leaving gross operating profit of \$684,229. Interest, development, and taxes reduced this to \$560,614, while other revenue left a surplus of \$596,738. Assets include cash, copper, and stores worth \$611,725; liabilities include accounts payable, interest on bonds, and taxes, totaling \$176,833. Dividend No. 4 absorbed \$150,000. The surplus stands at \$1,683,180. The net cost of copper, after deducting gold and silver content, was 11.42c. per pound. All departments have shown general improvement in their ability to operate at lower cost. The Shannon-Arizona Railroad Co., a subsidiary of the Shannon Copper Co., earned \$15,723 above interest requirements. The latter's fiscal year will be changed to conform to the calendar year.

### CALIFORNIA

#### AMADOR COUNTY

(Special Correspondence.)—At the Hardenburg mine the new 3-compartment shaft is down 1075 ft. A station and 300-ton ore-bin have been cut at the 1000-ft. level, and a cross-cut driven west to the old Hardenburg vein, and a drift is being driven on this vein. The formation is typical of the Mother Lode in this district. The 1000-ft. level gives more backs below the workings of the old mine than can be economically worked from one level, so at 850 ft. an-

other chute and station is being cut out, from which point cross-cutting and driving will be started. A 20-stamp mill, the ironwork of which is being made by Knight & Co., Sutter Creek, is being built, and will be finished in the latter part of January 1913. Power throughout will be electric, supplied by the Pacific Gas & Electric Company.

Jackson, November 25.

#### INYO COUNTY

During October the mill of the Skidoo Mines Co. crushed 717 tons of ore for the company and 435 tons for lessees, producing bullion worth \$15,551, including \$3264 from royalties and custom milling. Operating and development costs totaled \$5034, leaving a net profit of \$10,517 for the month.

#### KERN COUNTY

A rich discovery of gold ore is reported at the Tropico mine, near Rosamond, the next station to Mojave on the Southern Pacific railroad, and 80 miles from Los Angeles by automobile. The mine is in a detached section of the foothills near the Tehachapi range, at an elevation of 2600 ft. A drift, 190 ft. long, has opened ore worth from \$5 to \$1000 per ton; a winze and raise driven from the drift have returned \$560 per ton. Another orebody 15 ft. wide, with high value in gold, has also been opened. The country rocks are rhyolite, dacite, and andesite. The Tropico M. & M. Co. holds a bond and lease on the claims and is composed of Los Angeles men.

The Yellow Aster M. & M. Co. is employing 225 men. A storage tank to hold 500 tons of oil is being built at the southwest end of the glory-hole.

#### NEVADA COUNTY

At the 700-ft. level of the Fruitvale mine a station has been cut out and a raise driven to the hanging wall of the vein. Work has been temporarily suspended at the Black Bear claim. Rich ore has been discovered at the True Blue mine.

#### PLUMAS COUNTY

The Lost Creek district was extensively worked about 1862, and produced a large amount of gold where 'break-outs' occurred from the gravel channel higher up in the Mooreville ridge. According to gravel miners, the proper channel has never been opened, as a long bedrock adit was necessary to reach it. A company interested with G. Sanborn, manager of the Antlered Crest mines, near La Porte in this country, expects to start work on this long adit this season, using Burleigh drills.

#### SHASTA COUNTY

In the president's report to the stockholders in the Northern California Power Co., it is stated that within seven months two of the smelters in the county will resume work. Rate cutting by the Sacramento Valley Power Co. had reduced the Northern company's earnings, and the Sacramento company's entire holdings were purchased for \$1,760,500. Gross earnings for the past fiscal year were \$706,933. The present load is 34,740 hp., leaving 20,000 hp. installed and ready for delivery as soon as storage is finished. There are at present 7450 customers for power, light, and water.

The large dredge, costing \$150,000, belonging to the United States Gold Dredging Co., working between Redding and Middle Creek, sank in the river on November 29. The boat is said to have a weak hull, and this is the second time it has sunk. The machinery will be saved.

#### SISKIYOU COUNTY

This county was represented at the American Mining Congress, at Spokane, by gold and quartz specimens worth \$12,000, in charge of C. L. Proebstel and L. A. Nash. The exhibit is the property of the county and is displayed at public expense. Large nuggets and pans of coarse gold are in the cases. The county plans to enlarge the exhibit for display at the San Francisco exposition in 1915.

#### TUOLUMNE COUNTY

The Gold Mountain Water Co. has sold its entire Sonora water system to the Sierra and San Francisco Power Co. for about \$40,000. It is intended to thoroughly develop the system, and renew pipes about Sonora.

## COLORADO

### CLEAR CREEK COUNTY

(Special Correspondence.)—The new 10-stamp mill situated near the portal of the Empress adit on Covode mountain will be started within ten days. Ore will be treated from the Pioneer mine. S. L. Work is operating under bond and lease. An important discovery has been made on the Bloom property situated on Democrat mountain. In the breast of the adit a 6-in. streak of polybasite has been found which shows assay values of 179 oz. of silver per ton. Crist & Sons are the owners. Parker & Co., leasing on La Plata mine, have started shipments of ore which bring a settlement of 1320 oz. silver per ton. The vein is 5 in. wide. Ground has been broken for the new mill to be erected at the Pelican mine by the Clifford Exploration Co. The plant will adjoin the Pelican mill and the initial capacity will be 100 tons. Edison concentrating machines will be installed. The Enterprise mine on Douglass mountain is receiving attention. This is a zinc property and a 10-in. orebody is exposed in the breast of the adit. D. M. Titus is owner. E. Wing has taken a lease on a block of ground on the Silver Glance mine on Democrat mountain. Driving has been started on a streak of ore 3 in. wide which is worth 391 oz. silver

MAP OF COLORADO.

per ton. A heavy tonnage of lead and zinc concentrate is being finished at the Scotia mill. Ore is being treated from the Pelican mine, work being done through the Diamond adit. F. Graham is lessee.

Georgetown, November 26.

### GUNNISON COUNTY

At 1300 ft. from the portal of the Copper Mountain adit of the Brant Independent Mining Co., a 2-ft. orebody has been opened. At the time the ore was thought to be 'rosin' zinc, but tests gave no zinc in the ore. Examinations made at the Golden School of Mines and by a specialist at St. Louis proved that the mineral was strontianite.

### LAKE COUNTY (LEADVILLE)

The Arkansas valley plant is blowing in a new furnace, making five in full blast, and all of the roasters are working full time. Car shortage is improving daily. The Balkan war has affected the labor market in Leadville, and the Arkansas plant has difficulty in securing sufficient men. A zinc buyer for one of the largest zinc companies in the United States recently stated in Leadville that there is no question that the day will come when zinc plants will be able to handle 18% ore profitably, but at present all the plants are getting plenty of ore of a good grade and few bother about the low-grade material.

### OURAY COUNTY

During the past two months several alterations have been made to the mill of the Wanakah Mining Co. A grinding-pan is now used for regrounding tailing. Slime tailing is run over a Deister table, which produces a very clean concentrate. Concentrate is now handled automatically. It is elevated to a sampler, from which it flows to a series of settling-tanks, each holding one carload. When filled, a car is placed opposite the door of a full tank, and the concentrate is allowed to fall into the car. Mr. Moule designed this system and it works well.

### ROUTT COUNTY

Final plans have been made for the erection of a 400-ton mill and smelter for the Royal Flush mine at Hahn's Peak. H. O. Granberg, manager for the company, stated that over 10,000 ft. of development has been done, and \$200,000 spent in the mine alone. The mill will be situated 2½ miles north of Hahn's Peak, and will be connected with the mine by a tramway 7700 ft. long.

### TELLER COUNTY (CRIPPLE CREEK)

The water trouble at the Vindicator and Golden Cycle shafts, at the east side of the district, has now been overcome by the installation of electric pumps in the latter shaft. The water is lifted to the 100-ft. level, and then flows through the Roosevelt tunnel, at a reduced cost compared with steam pumps. The electric pumps consist of two sets of 175-hp., 30-cycle, 2300-volt motors, driving triplex pumps at the 1600-ft. level, each pump lifting 400 gal. per minute. The motors are of the two-speed type. On a 24-hour basis the units will have an 85% load-factor. It is expected that the new pumps will save their cost in 15 months. On November 24 burglars broke into the Wild Horse mill, on Bull hill, and stole precipitate valued at \$600 from the zincboxes, and got clear away. They were evidently familiar with the plant.

## IDAHO

### BLAINE COUNTY

At the Wilbert mine considerable development is being done, and the large surface orebody has been put in shape for winter work. At present there is a 25-ft. face uncovered. The ore deposits are flat and show layers of ore in which there is some waste mixed. Since the mill started there has been a gradual improvement in the concentrate produced. Three additional concentrating-tables were installed in November which increased saving by over 5%, and when two others are at work extraction will be about 80 per cent.

### SIIOSHONE COUNTY

(Special Correspondence.)—Drilling and shoveling contests were held during the visit of the American Mining Congress to this district, and proved of interest. In the former, the trial consisted of drilling 15 minutes in hard grano-diorite, using ⅞-in. steel and a 9½-lb. hammer, and was won by Stokes and Germain, who drilled 36⅞ in., followed by other teams doing 32⅞, 32½, and 32⅜ inches.

In the shoveling trials, 3 cu. yd. of 1-in. stone and sand had to be shoveled over a 3-ft. wall. This was done in 7 min. 2 sec., 8 min. 15 sec., and 8 min. 20 sec., respectively. Wardner, November 30.

Development at the Snowstorm Extension group is promising. The adit has been driven 1900 ft., and the face is about 1500 ft. below the surface. One cross-cut has been driven 380 ft. and two others about 30 ft. each. There is plenty of water and timber on the property. The annual meeting of the Black Traveler Mining Co. was held last week at Mullan. The vein has been cut at a depth of 320 ft., and has been opened for 87 ft., showing 18 in. of ore worth from 6.5 to 11.5% of copper and 6 oz. of silver per ton. At the Marsh mine the new owners will spend \$50,000 in developing the silver-lead orebodies in the property. New machinery is on the ground. From an orebody on the 800-ft. level 60 tons per day is being produced. The Empire Mining & Development Co. has acquired the King and Wonder claims on Pine creek. High-

grade copper ore has been opened in the 1800-ft. level of the National Copper mine adit, which is 4500 ft. long.

During October the Mammoth mill treated 16,933 tons from the Stewart mine and saved 73.12% of the silver and 84.59% of the lead, the concentration being 8.31 to 1. Mine expenses were: breaking ore, 41c. per ton; tramming, 15c.; gravity tram, 3c.; timbering, 49c.; shoveling 31c.; and other sundry costs bringing the total to \$2.14 per ton. Development cost 23c., making mine costs \$2.38 per ton. Milling costs totaled 32c. per ton. The month's output was worth \$109,540, and net profits were \$62,255.

Visitors to the sessions of the American Mining Congress at Spokane visited Wallace on November 30. There was a dinner and entertainment in the evening. On Sunday morning they inspected the large electric hoist at the Hecla mine. From Burke the mining men went to Mullan, and electric trams carried them two miles into the mountain

PART OF IDAHO.

to see the large underground station. The Morning mill was inspected, and the McQuisten tubes seen in operation. Sunday afternoon the visitors spent at Kellogg, where are the Bunker Hill & Sullivan and Federal company's Last Chance mines.

The Federal M. & S. Co.'s net earnings for October were \$116,000, as compared with \$87,000 in September and \$60,000 in August. The company operates the Last Chance mine at Wardner, the Morning at Mullan, and Standard Mammoth at Mace.

## MICHIGAN

### HOUGHTON COUNTY

The Calumet & Hecla Mining Co. has declared a dividend of \$12 per share, calling for a distribution of \$1,200,000, and a total to date of \$122,650,000. The Superior Copper Co. is developing the West lode, which is said to be averaging 50 lb. of 'mineral' per ton. The Quincy has declared a dividend of \$1.50 per share, making a total of \$5 per share for this year. The copper production for 1912 is estimated at 22,250,000 lb., as against 22,252,943 lb. during 1911, and profit as \$1,280,000, against \$489,737. Total cost per pound of copper is 10.63c. During the first ten months of the current year Calumet & Hecla has produced 58,301,646 lb. of copper; Osceola, 14,792,925 lb.; Ahmeek, 13,568,955 lb.; Tamarack, 6,450,004 lb.; Isle Royale, 6,696,-

291 lb.; Allouez, 4,474,780 lb.; Superior, 3,401,709 lb.; and Centennial, 1,370,435 lb. The Calumet & Hecla Co. is making a large installation of 65 motors, of 40 hp. each, for equipping its mines and smelters with electric drive. The motors are being supplied by the General Electric Company.

## MONTANA

### FERGUS COUNTY

The New Mine Sapphire Syndicate, a British corporation, shipped over two tons of raw sapphires last week from its Yogo mines to the London office. About two such shipments are made annually to Europe, where the sapphires are cut into gems. Many are then returned to this country for sale, having to bear the addition of heavy import duties. The raw stones are heavily insured against loss during transit. The Yogo sapphire mines are now the largest in the world, and the occurrence of the gems is unique. They are found in disseminated crystals through basic dikes called monchiquite by petrographers. The dike rock slacks on exposure, and the sapphires are concentrated from the resulting material either on concentrating tables or in sluice-boxes.

### SILVERBOW COUNTY

(Special Correspondence.)—Sunday work has been resumed at the mines of the Anaconda company, but the continuance of the same depends on the ability of the smelters at Anaconda and Great Falls to deal with the ore which is being hoisted. The shaft of the Tuolumne mine is down 2000 ft. Net earnings in October were \$33,000. There is little prospect of a dividend this year. The Butte-Alex Scott has opened a vein of rich ore on the 200-ft. level. Ore shipments are to be increased to 250 tons per day. A vein 20 ft. wide, averaging over 4% copper, was opened on the 1800-ft. level. At the North Butte, on the 2600-ft. level, an orebody has been proved 15 ft. wide, carrying bornite and glance, and will average 6% copper with gold and silver. Thomas F. Cole and other Duluth capitalists have been in Butte for several days, and have organized the Rainbow Lode Development Company.

Butte, November 27.

## NEBRASKA

Considerable interest has been aroused in the discovery of soluble potash salts in certain lakes in western Nebraska which are shallow and are from 50 to 500 acres in extent, occupying depressions among the sand hills. Jesse lake covers about 400 acres and varies in depth from 30 in. to dryness. Samples of water tested at the Mackay School of Mines, at Reno, Nevada, showed the following results:

Sample.	Gm. soluble salts per 100 c.c. dried.	K <sub>2</sub> O in total salts.
No. 2 .....	2.90	29.91
No. 3 .....	3.34	40.09
No. 4 .....	47.72	24.97
No. 5 .....	1.32	....
No. 6 .....	2.08	....

Concentration varies with the different stages of the lake. Experiments are being made on the property either to market crude salts or extract the potash and other by-products.

## NEVADA

### ESMERALDA COUNTY

A suit has been filed in the District Court against the owners of or claimants to the Dewar claim, in the Klondyke district. The case is somewhat complicated, but the property is regarded as one of the best in this promising district near Goldfield.

The estimated November production of the Goldfield Consolidated Co. is as follows: Ore treated, 27,614 tons; gross value recovered, \$429,000; operating expenses, \$185,000; net realization, \$244,000.

### CLARK COUNTY

A lease has been taken and work started on the famous 600-ft. level of the Quartette mine. From this level ore termed 'crysocolla,' containing free gold, was mined, and

large dividends were paid. A cave-in occurred some years ago and the stopes were lost, and it is expected that much skill will be needed to get through.

#### NYE COUNTY

The ore from the Steffner lease of the Manhattan Consolidated company is refractory, and a roasting-furnace is to be erected at a cost of \$12,000. Antimony has kept extraction down from 65 to 80% by amalgamation and cyaniding, and 96% is expected to result from the new process.

Word was received at Manhattan last week that potash had been discovered by the Railroad Valley Saline Co., which has been drilling during the past summer, and a rush has set in for that district. An automobile load of Tonopah men has gone out, and others will follow.

#### STOREY COUNTY

All the pumps in Ward shaft have been taken out, the station at 2100 ft. braced up, and the shaft closed indefinitely.

### NEW MEXICO

#### SOCORRO COUNTY

Development at the Ernestine M. Co. continues in the same excellent grade of ore. Before using the new automatic sampler for the custom ore business, the equipment at the Deadwood mines is undergoing a series of tests in conjunction with the old system of sampling, to determine its accuracy, and after a few further adjustments, all ores will be handled by it. The mill is running steadily, averaging 350 tons per week. Grading is under way for the permanent shaft at the Johnson mine of the Oaks Co. and plans are being perfected for extending the adit through to the end-line. At the Pacific, good ore is coming from the stope and the several development headings. The Consolidated, being worked under lease from the Socorro Mines, is yielding an excellent grade of milling ore. Work has just been started on the Trilby group and it is the intention to ship ore to one of the custom mills. A gasoline hoist may be purchased within a few weeks. Some of the best ore now milled in the district is coming from the Little Charlie mine of the Mogollon Gold & Copper Co. Arrangements have been made with one of the local plants to furnish current and an electric hoist will be installed.

### OREGON

#### GRANT COUNTY

(Special Correspondence.)—At the Ben Harrison mine, at Granite, the mill construction is finished, and 20 stamps, vanners, and a tube-mill are being installed. By the end of the current year it should be working full time. The mine is well developed to a depth of 500 ft. with an adit, and a shaft in the adit 100 ft. A 16-drill, electrically driven air-compressor has been installed.

Granite, November 19.

### SOUTH DAKOTA

#### LAWRENCE COUNTY

Two of the Black Hills operators, the Wasp No. 2 and Golden Reward, have installed Donaldson tilting furnaces for melting precipitate. Many advantages are claimed for this furnace, and in this district, where good coke is expensive and not easily secured, these crude-oil furnaces are desirable.

Open weather so far this fall has materially benefited the miners who are doing outside work. There has yet been no snowfall worth mentioning, a decided contrast to last year, when by the middle of November there was deep snow and good sleighing. Indications point to a mild winter, a boon to the operators, some of whom were forced to shut down last winter on account of the severity of the weather.

### UTAH

#### BEAVER COUNTY

Operations at the South Utah mine during the year ended June 30 resulted in a loss of \$31,114. The report of production from the general manager covers the period from September 1, 1910, to June 30, 1912, when 426,002

tons of ore was milled, averaging 1.142% of copper. The yield was 5,747,983 lb. of copper, 47,002 oz. of silver, and 2413 oz. of gold. Ore shipped totaled 701 tons, averaging 12.39% copper with some gold and silver. The ratio of concentration was 12.51 to 1. The total cost per pound of copper was 15.5c. Between the 700 and 800-ft. levels there remain 90,000 tons of 1.5% copper ore, and 15,000 tons of 1.4% ore between the 700 and 600-ft. levels. Assets include copper, gold, and silver, and supplies on hand worth \$138,318.

#### SALT LAKE COUNTY

It is stated that after several months' trial of the rolls of E. A. Wall they have been discarded, having proved unsatisfactory. He has instituted a suit against the Ohio Copper Co. for \$36,000 for payment for the rolls. Between 1700 and 2000 tons per day is being treated in two sections of the mill. It was in the second section, temporarily out of commission, that the Wall rolls were installed in an effort to secure a better recovery from the copper ore. When other machinery is installed the mill should treat at least 3000 tons per day. In compliance with the reorganization plan, there has been canceled bonds worth \$240,000. Less than 50,000 shares remain to be taken by the underwriters. On November 27 the ore shipments from the Utah Copper mines was 21,000 tons. Wages have been increased from December 1.

#### UTAH COUNTY

During the year ended November 1 the Colorado Mining Co., at Provo, produced 11,191 tons of ore worth \$247,899, with a net value of \$153,636. The fiscal year started with cash on hand totaling \$110,748, and closed with \$103,060. When the Knight mill is working, low-grade ore from the mine can be handled at a profit.

### WASHINGTON

#### STEVENS COUNTY

The Aurora Copper Mining Co., at Chewelah, will spend \$100,000 in new plant. It will be a duplicate of the United Copper, and have 100 tons capacity. The ore from the mine will be carried by aerial tramway a distance of 5280 ft., with a fall of 750 ft. It is intended to consolidate the power-plants of these two mines. The new machinery at the Copper King mine is now working, and 20 men are employed on three shifts. An official map of the Chewelah mining district is being prepared by R. B. Thomas, mineral surveyor.

### CANADA

#### BRITISH COLUMBIA

At Grand Forks smelter the Granby company is constructing a second slag conveyor, really an addition to the present system. The original plant, which is a belt conveyor, carries slag or waste material to the north end of an old dump, while the present installation will convey slag to the south end. During the week ended November 23 the Granby smelter treated 23,844 tons, one furnace being down for a few days, the total for the current year being 1,118,459 tons. The shipping mines of the Boundary district sent out 35,168 tons during the week. The British Columbia Copper Co. treated 15,255 tons at the smelter at Greenwood, making a total of 580,180 tons for the year.

It has been decided to increase the capital of the Kootenay Gold Mines Co. to \$500,000. On the Hardscrabble vein 900 ft. of driving has opened over 10,000 tons of ore. Platinum has been found in the dikes cutting the orebody.

#### YUKON

The Yukon river terraces on the left limit, seven miles below Dawson, which were staked early in October, are to be the scene of the most systematic undertaking in deep-channel placer mining in the history of the Yukon. It is proposed to drive an adit from the face of the hill through the bench and avoid shaft-sinking. It will also serve to drain the claims. This is the first adit started in the Yukon to sink for channels, or what is locally called 'second bed-rock.'

## KOREA

The Chosen Mining Co. has just bought a Lane slow-speed mill for its plant at Yeng Byen, and if the results obtained are as satisfactory as anticipated six or seven more mills of the same type will be installed. These are the first mills of the kind to be employed in Korea, and the results obtained in operation on the Yeng Byen ore are awaited with much interest.

## MEXICO

(Special Correspondence.)—Notwithstanding reports to the contrary issued from Mexico City, the country is in a state of chaos. Many mining companies have been robbed of money, powder, rifles, mules, and all kinds of supplies, and it is never known when other bands of rebels will descend on the districts. As the fear of Diaz recedes to the background, the lawless element of the country grows bolder and bolder.

Calabacillas, Sinaloa, November 18.

## CHIHUAHUA

Rebels have captured W. N. Fink, superintendent of the San Toy Mining Co. at Santa Eulalia, and are holding him for \$5000 ransom. The money was sent out by the company, and he was released, and stated that he had been fairly well treated. The rebels took horses from the San Toy corral, and stores worth \$5000 from Ketelson and Degetan stores in the town. They also went to the Santo Domingo camp for plunder, but retired on learning that the camp was armed.

Mining men in this state say that a revival in the mining industry is evident, judging by the number of denouncements made each day, while more prospectors than ever are in the hills.

At the end of the 1100-ft. adit, at a depth of 650 ft., of the Julieta mine at Troya, a rich orebody carrying gold has been cut. This mine is owned by Santa Rosalia people, and is managed by Paul Ginther. During the revolution the property was worked as usual.

At the smelter at Morse a new clubhouse for employees is being erected, with a special apartment for the women of the colony. J. R. Enlow is superintendent. On November 15 the smelter treated 800 tons. Paul and Henry Ginther, of Santa Rosalia, have acquired 1300 hectares of surface and underground rights in the Cerro de las Cruces section of the Carnargo district, containing large deposits of iron ore. These are near the projected Chihuahua-Monclova railroad, which the National Lines railroad will soon begin constructing.

A Canadian syndicate, headed by Paul Ginther, is to build a 2000-ton cyanide plant costing \$1,000,000, at Parral. It will be the largest mill in Mexico. The syndicate is acquiring more mining properties in the district and Minas Nuevas.

The Rio Tinto company has resumed work after a two weeks shut-down. The property is now protected by a garrison of Federal troops. In partnership with several others, Victoriano Huerta has made the following denouncements: 32 pertenencias on the Rancho de Avalos and 30 pertenencias in the Sierra del Carrizalillo in the Santo Domingo section of the Aldama municipality in the state of Chihuahua. J. H. Williamson, of Chihuahua, denounced 54 pertenencias in the terreno de la Hacienda de Tabalaopa, municipality of Chihuahua. Murray Crossette, of Cusihiuriachic, has denounced 30 hectares in the municipality of Cusihiuriachic and district of Benito Juarez. W. J. Wallace, of Cusihiuriachic, has denounced 10 pertenencias in la Sierra de Los Angeles in the municipality of Cusihiuriachic and district of Benito Juarez. Raymond Allison, representing Paul Ginther, has denounced 300 hectares in the Sierra de las Cruces in the district of Camargo and municipality of Santa Rosalia. Edgar Kock, of Parral, has denounced 6 pertenencias on the San Juanico and La Almanca ranches in the district and municipality of Parral. J. C. Gonzales has denounced 21 hectares in the mineral of Buena Vista in the municipality of Santa Barbara, and 6 hectares in the mineral and municipality of the same place.

## Personal

Professional men are invited to send news of their engagements and travels. Such news is interesting to friends.

C. F. TOLMAN has gone to Idaho.

CHARLES A. CHASE is at Telluride.

H. A. STROUT is here from Nevada.

W. M. BEAMAN is in San Francisco.

C. A. NONES has gone to New York.

FRED J. SIEBERT was in town recently.

D. W. BRUNTON has gone to St. Louis.

H. V. WINCHELL is at Wallace, Idaho.

HENRY KRUMB was in Missouri recently.

ERNEST GAYFORD was in Montana recently.

BERNARD MACDONALD has returned to Parral.

R. B. LAMB is in Cobalt on examination work.

R. ROBERTS is in Rossland, British Columbia.

FRED T. GREENE is in the Coeur d'Alene district.

J. H. G. WOLF has gone to New York and Philadelphia.

W. W. GRANGER has returned to Denver from South Dakota.

A. N. WINCHELL was in Minneapolis this week and has gone to New York.

RALPH ARNOLD was in San Francisco during the week and has gone to Texas.

E. L. BECK, of Goldfield, Nevada, has gone to Charcas, San Luis Potosi, Mexico.

FREDERICK G. CLAPP is at Bartlesville, Oklahoma, reporting on oil properties.

FREDERICK LAIST was in San Francisco last week and has returned to Montana.

C. A. H. DESAULLES is manager for the United States Zinc Co. at Pueblo, Colorado.

TAKESHI KAWAMURA has returned to Tokyo by way of Siberia, reaching there on October 25.

L. D. GODSHALL has been appointed manager for the Tecopa Consolidated Mining Company.

H. C. HOOVER has been elected a member of the board of trustees of Leland Stanford University.

WALTER LYMAN BROWN has returned to the Gold Coast as manager for the Abbontiakoon Mines, Limited.

J. W. MALCOLMSON and L. R. BUDROW were in San Francisco this week and have gone to Tonopah and Goldfield.

F. W. BRADLEY, L. L. JAMES, and JAFET LINDBERG are delegates from Alaska at the California Mining Association meeting.

HOWLAND BANCROFT expects to spend December in Boston, New York, and Philadelphia, returning to Denver near the holidays.

J. B. TYRRELL left for England on November 30. His address while in England will be 224 Salisbury House, London, E. C.

R. E. HAZARD, president of the Sambenigno Mines & Estates Co., Ltd., was in New York recently and will visit Europe before returning to Colombia.

ROBERT LINTON has recently been in Colorado examining some lead-zinc properties in the Kokomo district, and is now engaged in an examination of iron ore properties in Cass and Marion counties, Texas.

## Obituary

JOHN P. JONES died at Los Angeles on November 27. Born in Hereford county, England, in 1828, he was brought, at an early age, to Ohio, and in 1849 joined the rush of gold seekers to California, where between 1850 and 1867 he was prominent as an Indian fighter, miner, sheriff, and state senator. He went to the Comstock in 1867, where he became superintendent of the Kentuck and Crown Point mines. His faith in the Crown Point made him a rich man when the bonanza was discovered in 1870. Elected United States senator from Nevada in 1872, he held that office for over thirty years, retiring in 1903.

### LOCAL METAL PRICES

San Francisco is not a primary market for the common metals except quicksilver. The prices quoted below therefore represent sales of small lots and are not such as an ore-producer could expect to realize. Ore contracts usually call for settlements on the basis of Eastern prices, less freight and treatment charges. The prices quoted are in cents per pound, except in the case of quicksilver, which is quoted in dollars per flask of 75 pounds.

San Francisco December 5.

Antimony.....	12-12c	Quicksilver (flask).....	41
Electrolytic Copper.....	18-18c	Tin.....	52-53c
Pig Lead.....	4.60-5.55c	Spelter.....	84-84c
Zinc dust, 1400 lb. casks, per 100 lb., small lots \$9.50-9.75; large \$7.50-8.50			

### METAL PRICES

(By wire from New York.)

NEW YORK, December 4.—Copper is now quiet and sales are nominal; buyers are holding off for better prices. Lead is still quiet and weak with little demand. Spelter remains quiet. Average daily prices for the past week, in cents per pound, based on wholesale transactions, standard brands, are given below.

Date.	Electrolytic Copper.	Lead.	Spelter.	Silver, per oz.
Nov. 21.....	17.43	5.60	7.23	62
" 22.....	17.38	5.49	7.18	63
" 23.....	17.38	5.49	7.18	63
" 24.....	Sunday.	No market.

" 4.....	17.38	4.20	7.10	63

### SILVER

Below is given the average New York quotation, in cents per ounce, of fine silver for the months indicated:

	1911.	1912.		1911.	1912.
Jan. ....	53.81	56.25	July .....	52.57	60.67
Feb. ....	52.23	59.06	Aug. ....	52.17	61.32
Mch. ....	52.76	58.37	Sept. ....	52.43	62.95
Apr. ....	52.32	59.20	Oct. ....	53.37	63.16
May ....	53.31	60.88	Nov. ....	55.77	62.73
June ....	53.04	61.29	Dec. ....	54.85	....

### COPPER

Daily quotations on copper as published in this column represent average wholesale transactions on the New York market and refer to electrolytic copper. Lake copper commands normally from 1-5 to 1-4c. per lb. more. Below are average monthly quotations in cents per pound:

	1911.	1912.		1911.	1912.
Jan. ....	12.29	14.09	July .....	12.47	17.19
Feb. ....	12.26	14.08	Aug. ....	12.41	17.49
Mch. ....	12.14	14.68	Sept. ....	12.20	17.56
Apr. ....	12.02	15.74	Oct. ....	12.19	17.32
May ....	11.99	16.03	Nov. ....	12.61	17.31
June ....	12.39	17.23	Dec. ....	13.55	....

### COPPER SURPLUS

Figures showing the visible supply of copper at the beginning of each month are now widely available. Below are given the amounts, in pounds, known to be available at the first of each of certain months.

	U. S.	European.
January 1911.....	122,030,195	230,264,280
January 1912.....	89,454,695	178,329,920
February ".....	66,280,643	153,820,800
March ".....	62,939,988	141,125,680
April ".....	62,367,557	137,806,000
May ".....	65,295,368	134,176,000
June ".....	49,615,643	117,801,600
July ".....	44,335,004	107,817,920
August ".....	50,281,280	113,285,760
September ".....	46,701,376	112,743,680
October ".....	63,065,587	107,396,800
November ".....	76,744,967	

### UNITED STATES PRODUCTION AND CONSUMPTION

(Compiled from reports of the Copper Producers' Association)

	Production.	Domestic deliveries.	Exports.
October 1911.....	118,255,442	64,068,656	60,084,349
November .....	111,876,601	68,039,776	67,049,279
December .....	122,896,697	65,988,474	79,238,716
Total for 1911.....	1,431,938,338	709,611,945	754,932,733
January 1912.....	119,337,753	62,343,901	80,167,904
February .....	116,035,809	56,228,368	63,148,096
March .....	125,694,601	67,847,566	58,779,566
April .....	125,694,001	69,513,846	53,252,326
May .....	126,737,836	72,702,237	69,485,945
June .....	122,315,240	66,146,229	61,449,650
July .....	137,161,920	71,093,120	60,121,600
August .....	145,628,521	78,722,418	70,485,150
September .....	140,089,819	63,460,810	60,264,796
October .....	145,405,453	84,104,734	47,621,343

## LEAD

Lead is quoted ordinarily in cents per pound or dollars per hundred pounds delivered at St. Louis or New York. The difference is normally 15c. per hundred pounds, and any larger or smaller difference is promptly met by sales. The daily price in New York is published each week in this column. Below are the average quotations by months:

	1911.	1912.		1911.	1912.
Jan. ....	4.48	4.43	July .....	4.50	4.71
Feb. ....	4.44	4.03	Aug. ....	4.50	4.54
Mch. ....	4.39	4.07	Sept. ....	4.48	5.00
Apr. ....	4.41	4.20	Oct. ....	4.27	5.08
May ....	4.37	4.20	Nov. ....	4.30	4.91
June ....	4.34	4.40	Dec. ....	4.45	....

## ZINC

Zinc is quoted as spelter, standard Western brands, and based upon St. Louis or New York delivery. While New York quotations, as a matter of convenience, are commonly used, relatively little spelter actually goes to or comes from New York. The bulk is shipped direct from the plants in the Mississippi Valley to manufacturers, due allowance being made for freight. New York daily quotations are published in this column each week. Below are given averages by months:

	1911.	1912.		1911.	1912.
Jan. ....	5.45	6.42	July .....	5.70	7.12
Feb. ....	5.52	6.50	Aug. ....	5.95	6.96
Mch. ....	5.56	6.57	Sept. ....	5.86	7.45
Apr. ....	5.40	6.63	Oct. ....	6.10	7.36
May ....	5.35	6.68	Nov. ....	6.38	7.23
June ....	5.50	6.88	Dec. ....	6.30	....

Zinc-dust is quoted separately, the price being based upon the cost of spelter in Illinois and the cost of preparation. About half the zinc-dust used in the United States is imported through San Francisco. Delivery prices are determined largely by quantities and contracts.

## QUICKSILVER

The primary market for quicksilver is San Francisco, California, being the largest producer. The price is fixed in the open market, and, as quoted weekly in this column, is that at which moderate quantities are sold. Buyers by the carload can usually obtain a slight reduction, and those wanting but a flask or two must expect to pay a slightly higher price. Average monthly quotations, in dollars, per flask of 75 lb., are given below:

	1911.	1912.		1911.	1912.
Jan. ....	44.60	43.75	July .....	48.00	43.00
Feb. ....	48.40	46.00	Aug. ....	50.00	42.50
Mch. ....	52.50	46.00	Sept. ....	47.50	42.12
Apr. ....	50.90	42.25	Oct. ....	46.12	41.50
May ....	46.50	41.75	Nov. ....	45.50	41.50
June ....	46.50	41.30	Dec. ....	44.50	....

## TIN

New York prices control in the American market for tin, since the metal is almost entirely imported. San Francisco quotations, averaging about 5c. per lb. higher than New York, are quoted weekly in this column. Below are given average monthly New York quotations in cents per pound:

	1911.	1912.		1911.	1912.
Jan. ....	41.25	42.53	July .....	42.40	44.25
Feb. ....	41.61	42.96	Aug. ....	43.32	45.80
Mch. ....	40.16	42.58	Sept. ....	39.75	48.64
Apr. ....	42.18	43.92	Oct. ....	41.18	50.01
May ....	43.11	46.05	Nov. ....	43.12	49.92
June ....	44.61	45.76	Dec. ....	44.65	....

## Current Prices for Chemicals

(Corrected monthly by Braun-Knecht-Heimann Co.)

Prices quoted are for ordinary quantities in packages as specified. For round lots lower prices may be expected, while in smaller quantities advanced prices are ordinarily charged. Prices named are subject to fluctuation. Other conditions govern Mexican and foreign business.

	Min.	Max.
Acid, sulphuric, com'l, 66°, drums, 100 lb. ....	\$0.75	\$1.00
Acid, sulphuric, com'l, 66°, carboy, 100 lb. ....	1.00	1.50

## Current Prices for Ores and Minerals

(Corrected monthly by Atkins, Kroll & Co.)

The prices are approximate, subject to fluctuation, and to variation according to quantity, quality, and delivery required. They are quoted, except as noted, f.o.b. San Francisco. Buying prices marked \*.

	Min.	Max.
Antimony ore, 50%, 100 ton. ....	*\$22.00	\$25.00
Arsenic, white, refined, 100 lb. ....	0.054	0.054
Arsenic, red, refined, 100 lb. ....	0.08	~0.09
Asbestos, according to length and quality of fibre, 100 ton. ....	100.00	350.00
Asbestos, lower grades, 100 ton. ....	5.00	50.00
Asphaltum, refined, 100 ton. ....	10.00	20.00
Barium carbonate, precipitated, 100 ton. ....	42.50	45.00
Barium chloride, commercial, 100 ton. ....	42.50	45.00
Barium sulphate (barytes), prepared, 100 ton. ....	20.00	30.00
Bismuth ore, 10% upward, 100 ton. ....	*75.00 upward	
Chrome ore, according to quality, 100 ton. ....	10.00	12.50
China clay, English, levigated, 100 ton. ....	15.00	20.00
Cobalt metal, refined, f. o. b. London, 100 lb. ....	2.50	
Coke, foundry, 2240 lb. ....	14.50	15.00
Diamonds:		
Borts, according to size and quality, 1 carat. ....	2.00	15.00
Carbons, according to size and quality, 1 carat. ....	50.00	90.00
Feldspar, 100 ton. ....	5.00	25.00
Firebrick:		
Bauxite, 100 M. ....	175.00	
Magnesite, 100 M. ....	190.00	275.00
Silica, 100 M. ....	42.50	47.50
Flint pebbles for tube-mills, 2240 lb. ....	19.50	22.50
Fluorspar, 100 ton. ....	10.00	15.00
Fullers earth, according to quality, 100 ton. ....	20.00	30.00
Gilsonite, 100 ton. ....	35.00	40.00
Graphite:		
Amorphous, 100 lb. ....	0.014	0.024
Crystalline, 100 lb. ....	0.04	0.13
Gypsum, 100 ton. ....	7.50	10.00
Infusorial earth, 100 ton. ....	10.00	15.00
Magnesite, crude, 100 ton. ....	5.00	7.50
Magnesite, dead calcined, 100 ton. ....	20.00	25.00
Magnesite, brick (see firebrick).		
Manganese ore, oxide, crude, 100 ton. ....	10.00	25.00
Manganese, prepared, according to quality, 100 ton. ....	30.00	70.00
Mica, according to size and quality, 100 lb. ....	0.05	0.30
Molybdenite, 95% MoS <sub>2</sub> , 100 ton. ....	400.00	500.00
Monazite sand (5% thorium), 100 ton. ....	150.00	200.00
Nickel metal, refined, 100 lb. ....	0.45	0.60
Ochre, extra strength, levigated, 100 lb. ....	2.25	3.25
Platinum, native, crude, 100 oz. ....	45.00	50.00
Silica lining for tube-mills 2240 lb. ....	32.50	35.00
Sulphur, crude, 100 ton. ....	20.00	25.00
Sulphur, powdered, 100 ton. ....	40.00	45.00
Sulphur, 80%, 100 ton. ....	16.50	18.50
Talc, prepared, according to quality, 100 ton. ....	20.00	50.00
Tin ore, 60%, 100 ton. ....	475.00	500.00
Tungsten ore, 65% .....	425.00	475.00
Vanadium ore, 15% V <sub>2</sub> O <sub>5</sub> , 100 ton. ....	150.00	180.00
Wolframite (see tungsten ore).		
Zinc ore, 50 % up, 100 ton. ....	*15.00	20.00

## Concentrates

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

**METALLIC** filament lamps from Germany during the seven months of 1912 numbered 20,000,000, valued at \$6,000,000.

**MOLTEN SILVER** absorbs oxygen in large quantities. The gas is given off as the metal solidifies, and results in a blistered appearance of the bullion.

**I**N the gasoline-engine cylinder, the highest temperature reported is in the neighborhood of 4000°F. This is at the hottest portion of the exploding mixture of gas and air.

**METRIC CARAT** as the standard of weight for diamonds has been adopted by 50 leading jewelers of the United States. Under this standard a carat will weigh 200 mg., a reduction of 5.3 mg. from the old system.

**COAL** production of the world in 1911 totaled 1,300,000,000 short tons, of which the United States contributed 496,221,168 tons; Great Britain, 304,518,927 tons; and Germany, 258,223,763 tons, these three countries producing over 80% of the world's supply.

**REDUCERS** used in assaying are argol, flour, or charcoal. The relative reducing powers of these are, respectively, 1, 2, and 4. The lower powered reducers are generally preferred because the increased quantity required insures a more even distribution throughout the charge.

**PROOF** of the annual labor required by statute on unpatented mining claims is made by filing of affidavits to that effect. In Nevada the affidavit must be filed within 60 days after the completion of the work. It has been held that a single affidavit may cover the work on several claims, but in jurisdictions where the point has not been raised it is well to avoid the possibility of controversy by filing separate affidavits.

**THIRTEEN** nuggets weighing over 1000 oz. of gold each, have been found in Victoria, Australia. Their names and weights are: Nugget of 2844 oz. gross weight found in 1857; Welcome Stranger, 2520 oz. in 1869; Welcome, 2217 oz., in 1858; Blanche Barkly, 1743 oz., in 1857; Precious, 1717 oz., in 1871; Canadian, 1619 oz., in 1853; Lady Hotham, 1777 oz., in 1854; Sarah Sands, 1117 oz., in 1853; Viscount Canterbury, 1114 oz., in 1870; Heron, 1008 oz., in 1855; and three nuggets of 1034, 1011, and 1000 oz. respectively.

**GEOLOGICAL SURVEY** parties numbering 13 were employed in Alaska during 1911, including 12 geologists, 4 topographers, 2 engineers, and 30 packers, cooks, and other auxiliaries. The length of the season ranges from three to six months. The areas covered by geologic exploratory surveys amounted to 8000 square miles; by geologic reconnaissance surveys, 10,550 square miles; and by detailed geologic surveys, 496 square miles. Sixty-eight stations for measurement of stream flow were maintained in the Yukon-Tanana region.

**ZINC-DUST** is an impalpable powder which forms in the distillation of zinc when the zinc vapor is cooled too rapidly in the condensers or is diluted by too large a volume of gas. It may constitute a large proportion of the metallic zinc obtained in electrothermic zinc smelting; but in ordinary retort smelting it usually amounts to between 3 and 10% of the reduced zinc. The powder consists of metallic zinc, with about 10% of oxide, which probably exists as a film surrounding the metallic particles. Marketable zinc-dust must not contain more than 10% of zinc oxide, and must

pass through a 100-mesh screen. Its most important use is in precipitating gold from cyanide solutions, and is also used in the dyeing industry, fireworks, making hydrogen, and electrozincing.

**T**O produce high-grade cyanide bullion after the acid treatment of zinc-box precipitate, the zinc sulphate must be completely removed. The ordinary clean-up press does not as a rule wash efficiently. The treated precipitate should be allowed to settle as soon as all action has ceased in the acid tub. The zinc sulphate solution is then pumped through the clean-up press, and the settled precipitate agitated with a large bulk of hot water. Dilution with hot water should be carried on while filling the press. The cakes should be finally washed with clean hot water and air-dried.

**C**OST of forwarding sectionalized machinery over mountain trails is not entirely dependent on weight. A good mule will stand a double load of 200-lb. on each side better than a single load of 300 lb. in small compass. In the latter case the load shifts easily, causing the animal considerable discomfort. Loads of mixed machinery are often rearranged during the journey to suit the fitness or unfitness of particular mules. Loose fittings, bolts, and sundries should be securely sewed up in sacking before being boxed, since the average *ario* has no compunction about opening up even small cases if he thinks that the load may be distributed to better advantage by so doing. All markings on sectionalized machinery should be indelible, since the constant loading and unloading of the packages soon obliterates any ordinary paint mark.

**ANTHRACITE** produced in Pennsylvania includes an appreciable quantity of usable fuel recovered from the old culm banks by washeries, and the unsightly monuments to the wasteful methods of early times are disappearing from the landscape in the anthracite region. The quantity of coal recovered in the 22 years since the first washery was constructed in 1890 has amounted to about 50,000,000 long tons, considerably more than the total production of anthracite at the beginning of the period. In 1911 the washery product amounted to 4,136,044 long tons. In addition to the coal recovered from the culm banks, 94,647 long tons in 1911, and 91,833 tons in 1910, were recovered from the bottom of the Susquehanna river by dredges. In the bituminous regions the principal use of washeries is to improve the quality of the slack coal used in the manufacture of coke by reducing the ash and sulphur, although considerable quantities, particularly in Illinois, are washed in the preparation of sized coal for household use. The quantity of bituminous coal washed at the mines in 1911 was 12,543,114 short tons. The washeries yielded 10,999,481 tons of cleaned coal and 1,543,633 tons of refuse.

**M**EASUREMENT of stream flow by means of floats is easily carried out and gives results sufficiently accurate for many purposes, such as estimating the supply available for mining operations. The floats in common use are the surface, subsurface, and tube or rod floats. A corked bottle with a flag in the top and weighted at the bottom makes one of the most satisfactory surface floats, as it is affected but little by wind. In flood measurements good results can be obtained by observing the velocity of floating cakes of ice or debris. In all surface-float measurements the observed velocity must be multiplied by 0.85 to 0.90 to reduce it to the mean velocity. The subsurface and tube or rod floats are intended to give directly the mean velocity in the vertical. Tubes give excellent results when the channel conditions are good, as in canals. In measuring velocity by a float, observation is made of the time taken by the float to pass over the 'run'—a selected stretch of river or creek 50 to 200 ft. long. In each discharge measurement a large number of velocity determinations are made at different points across the stream, and from these observations the mean velocity for the whole section is determined. The area used in float measurements is the mean of the areas at the two ends of the run and at several intermediate sections.

## EDITORIAL

**S**MELTER FUME is not always obnoxious and an unusual case of its utility is seen at the mines of the Société des Mines de Cuivre de Catémou, east of Valparaiso in Chile. To lower the cost of food the company owns and operates ranches and vineyards, and it has been found that the SO<sub>2</sub> in the smelter gases is remarkably effective in protecting the grape vines from the ravages of the *Phylloxera*. Perhaps California metallurgists may one day find a suitable field for their activities in the Sacramento and San Joaquin valleys.

**H**OMESTAKE metallurgy has been pioneer work in many particulars, and the great mine 'which made South Dakota famous' is known for more than mere size. We present this week a general account of amalgamation as practised in the Homestake mills and will later publish accounts of other phases of the work. Mr. Allan J. Clark and Mr. W. J. Sharwood have collaborated in preparing an extensive paper on the practice and costs in the Homestake mills, which was read before the Institution of Mining and Metallurgy, November 21. It is from this, through the courtesy of Mr. Sharwood, that we abstract.

**C**OMPETITION on the Yukon is anticipated next year. The White Pass company, in an effort to stimulate traffic, has reduced rates to Dawson and announced the intention of running boats down the river to Fairbanks. In retaliation the Northern Commercial Company, operating steamers from St. Michael to Dawson, proposes to cut rates and make a stronger bid for traffic by the all-water route. Any lowering of rates will be of large benefit to the mining industry in the territory affected, and if it results, as it should, in stimulating new development, it will finally benefit the transportation companies as well. The Far North needs more and cheaper transportation above all else. The railway and steamship lines operating in that territory have severe conditions to meet and costs will always be high, but in many instances, at least, rates may be lowered to the mutual advantage of the companies and their patrons.

**W**ATER is a distinct menace in the California oilfields, and it is well that the association of the petroleum producers which has been formed in Kern county is showing so much activity. The results from the limited amount of work already done toward protecting the wells is so encouraging that a meeting was held in San Francisco last week for thorough discussion. Laws now in force are inadequate to meet the present situation, and Mr. W. E. Sutherland suggests that oil districts be organized under the Wright law providing for drainage and reclamation districts. Necessary funds are to be provided by assessment based on total production, and each district is to have the widest latitude in administration, since the problems differ so greatly in different districts. A law to this effect is to be introduced at the coming session of the California legislature, but concerted action is necessary to secure its passage, and the miners should join with the oil producers in their effort to safeguard so important an industry.

**S**ALE of the App mine under foreclosure marks the close of a mining enterprise long controlled by the late W. A. Nevills. The mine passes to the Central Land & Trust Company, of which Mr. T. W. Patterson, of Fresno, is president, in satisfaction of a deed of trust to cover a claim for \$155,000. It is one of the best known properties on the Mother Lode and has been reputed to contain a large reserve. The property became involved through repeated borrowings by Mr. Nevills. Repeated examination has failed to confirm his estimates of the amount of ore developed, and several prospective sales have therefore failed despite the excellent situation of the mine and the known presence of a large ore-shoot. A bad cave in the workings has complicated the situation.

**D**ISCUSSION at the meeting of the California Miners' Association held in San Francisco this week chiefly centred about the pragmatic phases of conservation of natural resources. In a meeting of those interested in the operation of mining properties it was only natural that the undesirable features of Federal administration of public lands, as affecting the mining industry, should become the subject of earnest and vigorous protest, and a superficial observer, noting the fervor of protest and the absence of any reply other than the paper written by Mr. W. C. Mendenhall and read by Mr. Charles G. Yale, might carry away a distorted view of the real situation. It was interesting to note that the appeal that the prospector should have the fullest opportunity to fare forth with his faithful burro in search of a treasure trove never failed to evoke the loudest and most prolonged applause. Similar discussion characterized the meeting of the American Mining Congress at Spokane, and has marked all recent meetings of mining men in the West. There is much to be said on the miners' side of the case; nevertheless many arguments adduced overlook the incontestable fact that this is 1912 rather than 1862, and by no possibility can Cripple Creek, the Klondike, Goldfield, and Tonopah be restored to pristine virginity. The general unrest on the part of the miner is none the less evidence that improvement can be made in the present situation. Unfortunately there is no general agreement as to what should be done. Chiefs of Federal bureaus respond to attacks made upon them by showing that in some cases complaint is based upon misunderstanding, and in others that the fault is in the law which they are charged to administer. Certainly there is need of change in the law and in practice as well. In the days of its infancy the California Miners' Association showed itself able to make its voice heard at Washington, and useful legislation was the result. Discussion is futile unless it ends in a well considered plan of action. Much as has been said of the present situation, it has not yet been covered adequately. Those who have taken part are mainly interested parties whose viewpoint is that of self-interest. What is needed is careful study by impartial men whose purpose is that of securing the maximum of good to the body politic. Responsibility for the laws rests with Congress, and to that body the miners must look for any permanent relief. Before Congress can enact legislation, however, that will be more than patch-work, it must be informed, and the only practicable way to inform Congress is through a study of the situation, in the West itself, by a competent investigating committee. Last year both the Forest Service and the Land Office were investigated at length by Congress, and it is worth noting that the miners did not present their complaints in any detail or in force. This was probably because the sessions of the committee were held in Washington. What is needed now is a real study of the difficulties as they exist in the West. This is the first prerequisite; securing the appointment of such a

committee and provision that it be composed of interested men is an achievement which should present no great difficulty to the California Miners' Association, and would constitute a real step toward remedial measures.

### Colorado's Testing Plant

An experiment of more than usual interest is being made at the Colorado School of Mines at Golden. In the effort to obtain the maximum of service for the state from the plant and equipment of the school, an unusually large and complete testing works has been built for treating ores in carload lots or even larger quantity. The building is of steel and concrete construction, and resembles an ordinary concentrating or cyaniding mill more than the conventional laboratory. It provides large open spaces, well lighted, and properly furnished with power, water, and other essentials. It is equipped with crushing, screening, roasting, concentrating, and other metallurgical machinery, all of full working size. Cyanidation and other equipment is to be added. When completed there will be little to differentiate this from other metallurgical mills save in the variety of the equipment and the presence of unusually complete supplementary laboratories. While all mining schools now maintain metallurgical laboratories, the school men have generally contented themselves, through choice or necessity, with more modest equipment.

In planning the testing works at Golden, Mr. Victor C. Alderson, the president, and his associates, had in mind three purposes: (1) To provide a working laboratory where students might become familiar with the actual machinery and actual processes used in metallurgy; (2) to furnish a testing works where any reputable engineer might conduct his own tests on ore at a nominal expense for use of plant; (3) to open the way for systematic research on the minerals and ores of Colorado with a view to better and more complete methods of treatment. With all these purposes, engineers within and without the state are doubtless in entire agreement, however much they may question the wisdom of the means employed when it comes to consideration of details.

Those in responsible charge of mining schools have ever before them the problem of maintaining a correct balance between theory and practice in the four years that students remain under their charge. For many years instruction was almost wholly in theory, and the future engineer was left to acquire his knowledge of practice in after life. Gradually, as the need of giving the students 'perceptive centres' came to be recognized, laboratory instruction was introduced. There is a fascination about machinery that goes to the head of an American like wine, and machinery in the laboratory leads to more machinery, until it has been questioned whether in certain institutions the instructors have not been lost in a maze of belts and cog-wheels. A large and imposing laboratory has advertising value, just as have the 'real pump and real water' seen on the modern stage. With our American trait of measuring success by numbers, any added equipment that resulted in more students and gave leverage for larger appropriations, loomed large. Unconsciously, we hope, instructors in the mining schools came to be swayed by the subtle spirit of the times, and scrambled. So far as training of mining and metallurgical engineers is concerned, we are firmly of the belief that fewer rather than more schools are desirable, and less rather than more elaborate machinery. In the school, students should be trained in theory and grounded in principles; in the field, the mine, and the mill are the places to learn practice, under the men who are doing things and under conditions involving responsibility such as students must learn to meet before they become engineers. If the

new plant at Golden had no other purpose than student instruction, we should look upon it as representing wasted money—money that might better be spent in sending the students to see the many excellent metallurgical plants that are found throughout Colorado. Fortunately the new testing plant is adapted to other uses, and with them we have more sympathy.

In every mining district the visiting engineer finds elaborate and well built mills that stand idle. In a large number of instances the reason lies in the fact that the mill was not properly designed to treat the ore available to it. Out of this fact and the insistent need that it indicates, has grown the business of testing ores in quantity, preliminary to designing and building a new mill. The largest and most successful companies never neglect this precaution—and they have their reward. At the Flat River mill of the Federal Lead Company, for example, there is a complete testing plant in which Mr. H. A. Guess tries proposed processes of treatment on ores from the scattered Guggenheim properties. The Anaconda Copper company maintains an extensive and expensive department for experiment and research. Nearly all manufacturers of mining machinery are prepared to demonstrate by test the efficiency of their devices on lots of ore shipped by possible customers. Independent commercial ore testing works, such as those of Ricketts & Banks, the General Engineering Company, Henry E. Wood & Company, and the California Ore Testing Company, are found in the principal cities, and in them ore in any quantity will be studied and tested. Competent engineers connected with these works will design treatment plants and will try on an ore any reasonable combination of standard equipment. It is impracticable for every engineer to maintain his own testing works, and equally impracticable for all to be permitted to run tests in private plants. There is therefore a field, how wide only experience can determine, for a general plant, free to the use of all engineers at nominal expense. We understand that owners of the commercial testing works in Colorado raised no objection to establishment of the state works at Golden, taking the broad ground that of any resulting increase in testing work, they would be able to obtain their share, and aside from that they would be better prepared than other engineers to use the state plant. Just how the matter will develop in practice remains to be seen, but any move to increase the care spent in selecting equipment and designing treatment plants, is highly to be commended. If the plant at Golden leads engineers and owners to know before they build, it will rapidly yield in savings far beyond its cost.

The third, and, as we see it, most important use to which the new testing works is to be put, is the definite study of materials and processes. It is proposed to use it to stimulate the mining industry of Colorado and to secure better results in treatment. Here lies a wide field in which there can be no competition. Colorado is a state of widely varied resources, and from being a gold-silver state is fast becoming one famed for the diversity of its mineral production. The tungsten and vanadium industry, but recently developed, suggest the possibilities that lie in development of entirely new industries. Improvement of old methods is not less important, since in Colorado as elsewhere thousands of tons of minerals are annually wasted because present conditions or present knowledge do not permit the making of a closer saving. No radical change is to be expected, but gradually the skirmish line of science must be followed by advance guard of technology, that the heavy infantry of industry may conquer new fields. The State never misuses money when it adds to human knowledge, and such a plant as that at Golden, rightly used, is potential of untold benefit. It must, however, be used. It avails

nothing to erect a building and assemble machinery unless men and funds be also supplied. But the first part of the task is accomplished, and the Colorado legislature about to assemble should make a definite annual appropriation in amount sufficient to assure full use of the equipment. We may differ as to details in the matter of the design and use of the new laboratory, but if it be made a Western Charlottenburg, the hopes of its founders and the wishes of its friends, among whom we count ourselves, will be justified.

### Decanting of Slime

Proposals to revert to decantation for general treatment of slime in cyanidation, are atavistic. The first great step in successful treatment of slime was the application of filtration to the problem. Fine material may be treated by decantation, but filtration introduces notable economies. The reason, as also the limitation to successful application of decantation, is not difficult to see when the behavior of finely ground material in solutions is analyzed. There is more pore space in a fine mud than in coarse sand settled in water, but the spaces between individual solid particles are narrower. It follows that the channels or openings through the mass are smaller and more tortuous. The mass is less permeable, and to obtain the same rate of flow extra force of some sort must be given to the liquid material which it is proposed to pass through the mass of solid particles. In settled sands the open spaces are sufficiently large to permit gravity alone to pull solutions through the mass at a rate that makes commercial results possible in treatment plants. With slime, to obtain the same rate of flow requires a vacuum or pressure.

The proposal to obviate this difficulty by continuous agitation and decantation has been made many times, and plants designed on this plan are in successful operation treating finely ground material that is really a sand. In them the individual particles are kept freely floating, each completely surrounded by solution, and never allowed to completely settle. As a result, there are no pore spaces, and the particle rather than the mass becomes important. The plan is ingenious and there is a field for such treatment plants, but not, we believe, a universal one. The reason lies in the difference in specific gravity between sulphides and silicious particles. The very ores that most need sliming for successful treatment are those in which the gold and silver is locked in the sulphides. It is to release this gold and silver that the ore is slimed. In practical operation of treatment plants where concentrates are cyanided, it is universally true that the sulphides are found to require more time for treatment than the other material. The relations of the valuable to waste metal are closer and complete solution of the gold and silver is harder to obtain. In continuous agitation and decantation, the first particles to settle are sulphides, and with them goes much of the gold and silver. The result is that the material which should receive the longest treatment really escapes from the system first, and there seems no general way to avoid this without completely destroying the process itself. The old process of decantation is available for coarse material; continuous decantation can be used on coarse and finer material and is useful for taking off the richer solution before vacuum filtration. For slime the best treatment is by filtration, and it is worth noting that the old Australian method, not covered by patent as it happens, of pressure filtration with hand cleaning, is still used. Our New York contemporary sees in decantation the future of slime cyanidation. We hold that for general use it is a backward step, however helpful it may be in special cases or in combination with filtration.

# The Rosario Cyanide Plant

By A. L. SWEETSER

Twenty-five miles east of Tegucigalpa, capital of the republic of Honduras, and two miles west of the town of San Jirancito, is situated the surface equipment of the New York Honduras Rosario Mining Co., which is the largest producer in Honduras, if not in Central America. The property may be reached either from Puerto Cortez, on the Gulf of Mexico, by a six-day trip over mountain trails on muleback, or from Amapala over a wagon road requiring four days for a saddle animal and about three weeks for heavy freight. Considering the isolated situation of the mine and the difficult problem of freighting heavy machinery to it, the following brief description of a cyanide plant recently constructed there should prove of interest.

The site selected for the erection of the plant has a slope of 37°, thus facilitating the transfer of material by gravity.

A general office which, in addition to other modern equipment, contains a printing plant for the production of the daily report sheets for the various departments and general notices; a large store-house and assay office, with latest appliances for facilitating rapid and accurate work; mechanical, electrical, and carpenter shops, and houses for the storage of lime, cyanide, and zinc. A central telegraph and telephone station connects all departments of the mine and mill with the general office, and also permits communication with all towns toward Puerto Cortez, on the Gulf of Mexico, and Amapala, on the Pacific, over a hundred miles distant. Dwelling houses, with well ventilated rooms, electric lights, toilet, and shower baths, and a large dining hall complete the number of buildings. A small ammonia ice-plant enables the cooks to serve some delicacies not often found in a mining boarding house. All the vegetables come from the company's farm, and all the lumber used in constructing the buildings and in the mine is produced in the company's sawmill from timber from the forest, 9 miles distant, also belonging to the company.

## CYANIDE PLANT

The general exterior arrangement of the cyanide plant can readily be seen from the accompanying photograph of the same, and the interior arrangement of the ore dressing machinery is shown by the flow-sheet.

### FLOW-SHEET

1. Fairbanks-Morse scale.
2. Tipple.
3. Grizzly.
4. 2 Gates crushers, type K 4.
5. 1000-ton ore-bin.
6. 20 1850-lb. stamps; four batteries of five each.
7. 2 Dorr classifiers.
8. 2 Allis-Chalmers tube mills, 22 by 5 feet.
9. 1 Dorr classifier.
10. 1 tube-mill to complete sliming of pulp.
11. 2 settling tanks, 10 by 20 feet.
12. Screen on which cyanide and lead acetate are dissolved by solution.
13. Pachuca tanks, 15 by 45 feet.
14. 2 storage tanks, 10 by 20 feet.
15. 2 Merrill filter-presses; capacity 220 tons.
16. 2 strong and weak-solution tanks, 10 by 15 feet.
17. Zinc-dust precipitation.
18. Refinery.

### OPERATION

The ore, as delivered at the mill, averages about 25 oz. silver and 0.46 oz. gold per ton. In addition to these metals the ore also contains copper, lead, iron, and antimony in small quantities. The stamps are in separate battery units, so that when it is necessary to make alterations, or repairs, only one battery of five stamps is hung up at a time. Each stamp weighs 1850 lb., drops 100 times per minute with a fall of 6 in. The stamp-duty is 10 tons per stamp per day, thus making the mill capacity of 200 tons daily, although an excess of 20 tons has frequently been treated. The ore is mixed with lime, in the bin, by means of wooden chutes from the crusher floor. Each battery is fed by Challenge feeders and the ore is crushed in the strong cyanide solution from the Merrill presses, which is pumped from the precipitation house by means of two Aldrich triplex pumps (10 by 10 in.) to storage tanks above the mill, whence it flows by gravity. The weak solution, similarly pumped, is used as a wash for the Merrill presses.

TRAIL THROUGH LOWLANDS. RAILWAY STATION IN HONDURAS.

The foundations consist of concrete piers which are sunk in the hillsides to a depth of 20 ft. and securely anchored to bedrock. In order not to disturb the natural condition of the loose gravel above the bedrock, all the holes for the foundation piers were not dug at the same time. For instance, where a building required two or three rows of five piers each, the order in which these holes were excavated and then filled with concrete was 1—4—2—5—3. This method prevented the loose surface material from sliding and causing the disturbed gravel to creep, as might have occurred were all the holes excavated at the same time. On these concrete piers steel I-beams were laid, on which were placed the buildings, consisting of board floors and corrugated iron sides and roofs.

Wherever the building required a large floor space, the gravel of the hillsides was cut down and leveled. Then retaining walls of concrete were built along the back and sides. The angle of these walls is 67°, and they have a thickness of 4 ft. at the bottom, but taper off to 1 ft. at the top. The back wall is also reinforced by concrete braces, built at an angle of 35°. These vary in height and thickness, according to the height of the retaining wall. The composition of the concrete used throughout the construction was 1 cement, 3 sand, and 5 parts of stone. All the concrete was reinforced, during the pouring, by the insertion of old mine rails, pieces of cable, and scrap iron. The total consumption of cement in the construction was 15,000 barrels.

In addition to the mill, there are the following buildings:

On leaving the settling-tanks the solution and pulp flow over a screen on which is placed the required amount of cyanide and 50 lb. of lead acetate. From repeated tests during the six months the mill has been in operation an average of 500 lb. of cyanide is required for each Pachuca tank of pulp. The pulp in the Pachuca tanks is agitated by means of compressed air supplied by an Ingersoll-Rand duplex compressor, 5 cu. ft. of air being furnished to each tank. The amount of sluicing water, used to remove the cakes from the filters, per ton of dry slime treated is about  $4\frac{1}{2}$  tons; the ratio of wash solution per dry ton of slime is 2.9 to 1.

Precipitation is accomplished by means of zinc dust agitated by compressed air. An extraction of 91 to 96% is obtained and the difference between the theoretical and the actual extraction is less than 1%. The press precipitate is

and that of the mine 600 hp. At the mine there are two 800-hp. air-compressors, producing 2000 cu. ft. of air for drilling purposes, and also six 5-ton General Electric mine locomotives which gather the ore on the different levels of the mine. It is sent to the adit-level and later to the mill, two miles distant. The mine has been in operation over thirty years and the underground workings now amount to 60 miles. The trackage of 35-lb. rails and  $2\frac{1}{2}$ -ft. gauge is being laid through the mine as rapidly as possible to facilitate the transportation of ore to the mill and the workmen to the various stopes.

All the machinery in the mill is direct connected to motors. The stamp units are belt-connected to a counter shaft driven by motors, which are in duplicate in case one should be out of commission. All wiring is in iron conduits and the lighting service at the mine, mill, on the surface, and in other

ROSARIO CYANIDE PLANT, SAN JUANCITO, HONDURAS.

melted into bars which average in weight about 125 lb. These are shipped to Perth Amboy, New Jersey.

#### ELECTRIC POWER

All of the mill machinery is motor-driven. General Electric induction motors, 60 cycles, are principally used. The Gates crushers are driven by 25 hp. form K motors, using 6.6 amperes and a 75-hp. form M motor, using 20.5 amperes, drives each tube-mill. For the pumps 25-hp. motors are used, 2 hp. for the Dorr classifiers, and 15 hp. for the filter-presses.

The present system of electric power dates back ten years, when the first electric plant was installed. From this time the electrification of both mine and mills has proceeded rapidly, until now there are two hydro-electric generating stations, furnishing 6600 volts and supplying 50 motors, having an aggregate capacity of 2100 horse-power.

The water, furnishing the initial power, is taken from the San Juancito and Escobales rivers, and conducted in a wooden flume  $3\frac{1}{2}$  miles to a point 1355 ft. above the town of San Juancito, whence it descends in a spiral-riveted, iron penstock, made with expansion joints to provide for changes in atmospheric temperature. The water pressure of 520 lb. per square inch acts on Pelton water direct connected to 6600-volt generators. The Guadalupe generating station is three miles below the town and utilizes the water escaping from the San Juancito spillway. Each station can, if necessary, carry the entire working load at a slightly diminished efficiency. The service is practically continuous, there being a demand on the power system at all hours. Electric power is transmitted to the sub-station at the mill, 2 miles distant, whence it is distributed throughout the mill, mine, repair-shops, assay office, and lighting system.

The average demand of the mill is approximately 450 hp.

buildings consists of 800 Mazda incandescent lamps and 25 arc lights. On the battery-floor of the mill carbon filament incandescent lamps are used, because the vibration due to the impact of the stamps causes a large breakage in the case of metallic filament lamps.

THE American Cyanamide Co. of Niagara Falls, Ontario, is making extensions to its plant, which, when completed, will cost about \$500,000 and will more than double the present capacity of the concern. The company is engaged in the manufacture of atmospheric nitrogen by the Frank and Caro process, the power being derived from Niagara Falls. During 1910, at the beginning of which year the company commenced the manufacture of cyanamide, the exports of cyanamide to the United States were valued at \$211,200, while during 1911 these exports had increased to \$338,775. The exports for the current year are expected to be much greater, making the additional plant necessary to keep pace with the growing demand.

A STRONG Johannesburg syndicate has been formed to work a promising occurrence of cassiterite on the edge of the Chishawasha valley to the east of Salisbury. T. R. Williams, formerly consulting metallurgist to H. Eckstein & Co., is busy investigating the treatment of the material. A large tonnage is already partly proved and there is talk of erecting a compressor plant with a view to expediting development.

PRECIOUS METAL produced in Dutch Guiana during 1911 amounted to 30,713 oz., which is 4061 oz. less than the output of the preceding year. This production was obtained by means of hand work by 'pork-knockers' (individual prospectors) and a few companies.

# Evolution of an Electrolytic Refinery—I

By HAROLD FRENCH

Most depositors of bullion at the San Francisco Mint, after they have paid their melting, parting, and refining charges, deductions averaging about  $\frac{1}{50}$  c. on the dollar, are interested to know how the silver and gold are separated from the base alloy preparatory to coinage. The public owns several Federal refineries which operate upon nearly \$100,000,000 worth of crude bullion each year. It is of importance to know how this work is conducted, whether or not it is managed with a due regard for efficiency and economy, and with studied efforts to improve this service for the benefit of producers of precious metals, whose interests the mints and assay offices are intended to promote. The impression prevails in many quarters that most government work is done in a more or less wasteful haphazard fashion, and that little attention is paid to 'taking up the economic slack.' That this has not been the case in the Mint and Assay service during the last decade is demonstrated by the many marked improvements in the processes of parting and refining at the several Federal plants.

## PARTING WITH $\text{HNO}_3$

Only within the past few years have the mint metallurgists discontinued the time-honored process of parting bullion with boiling acids and adopted the more up-to-date electrolytic system of separation. Although these older methods are no longer employed by the Government, they are still in vogue at some private refineries, for economic reasons which will be explained later in a comparison of the results obtained by the selection of processes most suitable for varying grades of bullion. An exposition of the former operations of the Mint parting plants may seem like a retrospect of ancient history, but the fact that the acid treatment is extensively employed in commercial work makes it of present interest. Occasionally an assayer is required to refine bullion on a small scale for the purpose of producing metals, and modification of the processes below may be resorted to with satisfactory results.

In the acid process it is important to carefully select crude bullion as free as possible from tin, antimony, bismuth, arsenic, and iron. If these impurities amount to more than 20% of the alloy they yield oxides, either insoluble or nearly so, which form a pasty coating over the surface of the metal and protect it from the attack of nitric acid. Whenever these metals are present in sufficient quantity to retard operations, it is necessary to fuse the base alloy in crucibles with nitre or ammonium chloride. At one time  $\text{HgCl}_2$  was stirred vigorously into the molten mass to expel volatile chlorides of these objectionable constituents, but its use was later abandoned. Extremely base bars were set aside for the sulphuric acid treatment, providing that they did not contain much lead or copper. The presence of copper was always welcome in alloys which were to be dissolved in nitric acid, as each part reduces the amount of silver that had to be added to the gold in order to render the alloy soluble. At first, from 2.75 to 3 parts of silver-copper-lead alloy were added to each part of gold. Of this, the greater part was silver, but the more copper the bullion contained the more rapid was solution. Although the consumption of nitric acid increases with the percentage of copper present, the saving in time effected was deemed more advantageous. Experiment led to the eventual reduction of the alloy of silver and copper to  $2\frac{1}{3}$  parts to one of gold.

Formerly the alloy was dipped from the crucible and poured with a circular motion into a galvanized iron tub of water, where it cooled in the form of granules, but in late years more satisfactory results were obtained by casting the metal into slabs 1 ft. long, 3 in. wide, and  $\frac{1}{8}$  in. thick. In this form the bullion while digesting would not pack into a sticky mass. The parting was performed in a 'corroding-house,' a rectangular structure, provided with sliding doors, and covered with a hood connecting with the flues.

About 3 ft. above the floor 12 compartments were built within the enclosure, arranged in two rows of 6 each. In each of these rested porcelain crocks 21 in. diam. and equally deep, surrounded by water, which was rapidly brought to the boiling point by the introduction of steam through an injector. Into each of these was placed a charge of 175 to 200 lb. of granulated alloys or slabs, covered with an almost equal weight of strong commercial  $\text{HNO}_3$ . In an hour the violent action had somewhat subsided, then steam was turned into the water bath and the crocks were kept boiling gently for 6 hours, when the greater part of the silver and the base metals had passed into solution. The gold remained in the form of a lumpy clay-like residue.

Water was then added to dilute the strong solution of nitrates, and after the subsidence of the suspended particles, the liquid was siphoned off into wooden tubs and emptied into the silver precipitation tank. Fresh water was again added to the crocks, and the contents vigorously stirred, allowed to settle, and the liquid again siphoned off and disposed of in a similar manner. The crocks were again filled with concentrated nitric acid, boiled, and stirred at frequent intervals for the greater part of another working day. This second charge of acid was saved and used on the next batch of granulated alloys or slabs, while the residual gold was repeatedly washed, first by decantation and finally by filtration through cotton cloth. The remaining 1 or 2% of silver and base metal was reduced to a trace by transferring the pulverulent gold to cast-iron pots and boiling with concentrated  $\text{H}_2\text{SO}_4$  for several hours. This solution was then ladled off, the gold dumped into wooden tubs, and washed with hot water, until the soluble sulphates had been removed by repeated decantation. The almost pure gold was then placed in a movable tank, fitted with a perforated false bottom, over which rested a filter-cloth. Hot water was run continuously through the filter until the contents were 'sweetened.' The gold was finally air-dried in an oven over a slow fire, transferred to crucibles in which it was toughened, if necessary, by oxidizing fluxes, skimmed with semi-fluid bone-ash, and melted into bars of bullion, ranging from 996 to 998 in fineness.

The solutions from the crocks, together with the washwaters, were emptied into a large wooden tank. Salt was thrown in, forming thick curdy silver chloride which required most vigorous stirring until all of the silver had been precipitated. Care was taken to avoid an excess of salt, on account of the slight solubility of silver chloride in sodium chloride. After the precipitation had been proved complete by testing with a few drops of  $\text{HCl}$  in a sample of the clear solution, the liquid was siphoned off, and the thick silver chloride was scooped into filters lined with cloth and mounted on trucks. Hot water was allowed to percolate through the mass on the filter until the soluble base chlorides were removed. The nearly pure silver chloride was then transferred to a rectangular, lead-lined tank, in which granulated zinc was added for the purpose of reducing the silver to its metallic form, according to the simple formula,

A pitcher or two of  $\text{H}_2\text{SO}_4$  was added to remove the undissolved lumps of zinc remaining after the chemical action had diminished. The reduced silver was then shoveled with copper scoops into the movable filters and thoroughly 'sweetened' with hot water. The finely granular metal was next placed in a cylinder where a powerful hydraulic press squeezed most of the moisture out of the mass and left it in the form of a cake, which, after being completely dried in an oven, was ready for melting. The final drying was formerly done over a wood furnace, but a steam-drying apparatus has been found to be a more rapid and economical method. The cakes were laid upon shelves of steam pipe

and in a couple of hours were fully desiccated. The resulting silver bars were comparatively free from objectionable base metal and usually assayed between 998 and 999 fine.

#### THE $H_2SO_4$ PROCESS

The high cost of operation weighed heavily against the  $HNO_3$  process. Not only was the initial cost of  $HNO_3$  high, but it was consumed without yielding any marketable by-product. Sulphuric acid could be purchased for as low as  $\frac{3}{4}$ c. per pound, while  $HNO_3$  ranged from 10 to 12c. per pound. Another disadvantage of the nitric acid process was the high cost of zinc which was used to decompose the silver chloride, which, as well as the copper contained in the crude bullion, was run into the sewer at a considerable loss to the Government. The manufacture of copper sulphate as a by-product at the end of the  $H_2SO_4$  process proved so profitable to the Government, that this method early superseded the older one. Base bullion containing a considerable quantity of lead and copper had to be subjected to the nitric acid treatment, since when the copper present exceeded 7% the basic sulphate was formed, which, being almost insoluble in boiling  $H_2SO_4$ , coated the bullion and greatly retarded the solution of the metals alloyed with the gold. The formation of lead sulphate was similarly objectionable.

To reduce the cost of refining operations, the Government installed complete sulphuric acid parting plants at the Mints. The history of the San Francisco refinery and its numerous improvements serves as a good example of practice. A long room on the west side of the building was used for boiling the auriferous alloy and precipitation of the silver, while a room 41 by 52 ft. contained the filter tanks, in which the precipitate was 'sweetened.' The floors were covered with a thick coating of asphalt, which, being impervious to acid, was readily cleaned whenever solutions were spilled. Underneath each chimney two large cast-iron kettles were placed over a coal-fired brick furnace. The funes were carried to the stacks through hemispherical hoods resting upon the kettle. Later improvements led to the use of a Roessler condenser, which effectively eliminated the disagreeable vapors of  $SO_2$ . Granulated metal slabs containing 2 to 3 parts of silver to 1 of gold were placed in these kettles, and  $H_2SO_4$  in sufficient quantity to effect its decomposition was added. Three parts of silver to one of gold permitted the best rate of solution. Larger quantities of silver were found to be detrimental, as the gold was left in a more finely divided state, and the particles suspended in the heavy solution were difficult to settle. Occasional slight losses occurred when the proportion of silver was too high. During the last few years of the sulphuric acid operations, the superintendent of the refinery reduced the alloy of silver to an average of a little over  $2\frac{1}{4}$  parts to 1 of gold. While the silver did not then dissolve so rapidly, the gold was recovered in a more easily collectible form, and the consumption of acid was less, with a corresponding decrease of labor and reagents. As a rule, the workmen were employed throughout the year, and time was not so great an object as it is now. Occasionally, when deposits suddenly increased, as during the bonanza years of the Klondike, the proportion of silver was raised, so that the parting could be rushed.

Generally, about 600 lb. of alloyed metal was the charge of each kettle, and usually two were run together. Out of the total of 1200 lb. which was parted each day, from 300 to 360 was fine gold. In terms of Troy weights, this would equal from 4375 to 5260 fine ounces per day, valued at an average of nearly \$100,000. Allowing 11 months of 25 working days per year, the old refinery could turn out \$27,500,000 each fiscal year. A typical run was made in 1900-1, when its output reached \$27,637,869.74 in gold and \$5,277,047.92 in silver, a total of \$32,914,917.66. With four kettles at full boiling, 10,000 oz. of gold could be turned out per day, together with nearly 25,000 oz. silver. But as most of this silver was used over and over again in the method of inquartation, the net production of silver used for coinage or sold as 'mint fine bars' was much less, the remainder being 'locked up' in the process

until accounted for in the annual settlement. The same consideration applied to the  $HNO_3$  process.

To each charge of 600 lb. of metal, about a ton of  $H_2SO_4$  was added. Formerly the refiners dipped this dangerous liquid into the kettles, receiving many an ugly burn. Later 1600-lb. drums were handled with great risk on an elevator and brought to the side of the kettles, where they were lifted by a chain block to a height sufficient to siphon their contents into the kettle by means of a bent iron pipe. As the acid used was 66°B., these siphons were always started by filling with the same liquid, as the effect when water is suddenly added to strong  $H_2SO_4$  is well known. In 1905 this cumbersome manner of manipulating these heavy drums was abandoned. A sump was sunk in the street into which the drums were dumped and the acid was elevated by compressed air to a tank in the loft between the chimneys. The gold boilers drew the acid for their kettles through pipes leading downward from the storage-tank, and regulated its flow by convenient stop-cocks.

Early each afternoon the kettles were charged with metal and acid. The gold boilers started fires beneath them, and watched the boiling carefully, retarding it with cold acid or lowering the heat if the action became too violent, so as to prevent an overflow. At the close of the day's work they would leave the locked kettles in the care of the Mint watchmen, who would replenish the fires at intervals during the night. By the next morning the slabs of alloy had been reduced to a pasty mass of brown gold submerged in a greenish-white solution of silver and base sulphates. From 30 to 50 gal. of fresh acid per kettle was added, and the sticky mass stirred until the gold remained in a granular form, with occasional lumps of undissolved alloy. The fires were allowed to die out, the solution cooled slightly, and the suspended gold allowed time to settle.

Two rectangular tanks, 18 ft. long, 5 ft. wide, and 3 ft. high, covered with a sloping roof of sliding doors and lined with heavy sheet lead, adjoined the gold-kettles. Slabs of copper 2 ft. long, 1 ft. wide, and 1 in. thick lay on the bottom of each tank or stood against its sides. Fresh water, as free from chlorine as possible, half filled the tanks. The hot solution from the gold-kettles was siphoned into these tanks of water. As its temperature exceeded 600°F., steam was generated with almost explosive violence. Crystals of pure silver sulphate formed upon the copper, giving a milky color to the water as some of the silver sulphate dissolved. A quadruple coil of lead pipe lay in the bottom of the tank, through which steam was passed to keep the solution at the boiling point, effecting more rapid precipitation of the silver by the copper. About seven years ago steam injectors were found to heat the silver solutions more rapidly, besides offsetting much of the evaporation by condensation of part of the steam. The solution was repeatedly agitated until tests with salt showed no traces of silver—usually after nearly two days' boiling. It then contained about 300 lb. copper and nearly 3000 lb. of  $H_2SO_4$ , for the most part free. This was well worth saving, but until 1901 a large part of it was permitted to run into the sewer at a heavy loss to the Government.

After the silver and base sulphate had been siphoned from the parting-kettles, the residual gold was ladled out into four small cast-iron pots, in lots of about 100 lb. apiece. The next morning these were placed over cylindrical furnaces, coal-fired, and boiled for four or five hours with concentrated  $H_2SO_4$ . About six 1-gal. pitchers of acid were added every hour until 1 o'clock, the previous charge having been removed. In later years the base metal was more readily extracted by stirring nitre into the boiling acid. When the last boiling bath became less turbid, indicating that only a fraction of 10% of silver or base metal remained, the solution was ladled and drained off, and the gold dumped into a wooden tub fitted with a cover. The nozzle of a hose was inserted through the top and hot water played upon the gold, the temperature of which was three times as high. The clouds of steam which were evolved were conducted upward through a

chimney. The metal had to be stirred carefully with wooden paddles to reach the highly heated core, so as to prevent loss caused by the spattering which would result if the metal came in contact with cooler water during washing in open tubs. "Taking the fire out of the gold" was the term the workers applied to this stage of the operations. It was finally washed by repeated decantations and filtration. After drying and melting, the gold was cast into bars assaying 996 to 999 in fineness.

The silver was recovered in two forms; 95% of it as granular metal from the precipitation-tanks where the silver sulphate had been reduced by copper. This was shoveled into the filter-cars, in which it was removed to the washing room. After thorough washing in hot water it became a mass of fine clear crystals. A pressure of 40 tons, exerted by a hydraulic cylinder, moulded the silver into cakes, which were melted as described. After boiling the gold a second day in the small pots, the remaining 5% of silver was removed and carried into a cast-iron receptacle on a truck to the 'sulphate tank.' The building of an overhead trolley in 1904 greatly facilitated the handling of this disagreeable liquid. Salt was added to the solution of silver sulphate, precipitating it as the chloride, which subsequently was reduced by zinc and sulphuric acid as previously described.

In 1901 more attention was paid to the recovery of copper, which hitherto had been largely wasted. The solution, free from silver, was siphoned from the precipitation-tanks in the refinery, down to a series of lead-lined vats in the interior court of the Mint. On the bottom of these, lead coils carried steam through four loops of pipe, which quickly brought the copper sulphate solution to the boiling point. This liquid averaged 26°B. at the beginning. Until 1901 this solution was boiled a few hours and siphoned into lead-lined crystallizing tanks at about 33°B. This insufficient concentration caused a meagre crop of crystals to form upon cooling, and most of the copper remained in the solution, which was then passed over iron. As this became coated with a little copper, action on the rest of the cupric sulphate ceased. In this way much of the copper was neither recovered as bluestone nor in the form of cement-copper, but was run down the sewer. This waste was almost entirely checked by changing the methods. The solutions were boiled until late in the afternoon, allowed to stand over night, warmed in the morning, and then siphoned off at gravity of 40°B. Large masses of crystals formed on the sides of the tanks and upon rows of sheet lead hung a foot apart on iron rods. After 8 or 10 days the mother-liquid was drawn down into several new tanks, where scrap iron readily precipitated the copper which had not crystallized. Baskets made of copper wire held this iron suspended in the solution, so that it did not pack on the bottom but presented a greater surface to the acid. The introduction of steam injectors heated the solutions so as to hasten the precipitation of the copper as well as causing the almost complete dissolving of the excess of iron. The first crop of crystals of copper sulphate were redissolved in a tank of boiling water, then drawn off at 30°B. into 7 finishing tanks, where the pure crystals formed. These were washed free of impurities, dried over a steam-heated lead floor, barreled, and sold as 'bluestone',  $\text{CuSO}_4 \cdot 5\text{H}_2\text{O}$ ; 4 lb. of this contains 1 lb. of copper and nearly  $\frac{1}{2}$  lb. of  $\text{H}_2\text{SO}_4$ . The average cost of materials and labor was 4 to 4½¢. per pound, while the bluestone sold at a profit of about 1¢. per pound. In six years nearly \$25,000 was saved to the Government by the care taken in recovering this copper, which would have been wasted if the older methods had been continued. The sale of bluestone not only repaid the cost of the copper used in precipitating silver, but returned a considerable fraction of the amount paid for sulphuric acid. Frequent improvements had reduced the cost of refining the average grade of gold bullion received by the San Francisco Mint to less than 3¢. per ounce, which was more than made up by the parting charges alone. There seemed to be no further progress possible in the development of this process, and the Gov-

ernment therefore decided to experiment with the electrolytic methods of separation.

#### EXPERIMENTAL INVESTIGATIONS

Toward the close of the nineteenth century, technical requirements necessitated purer grades of metals than the acid-parting plants could economically produce. The older methods of treating metallurgical products by smelting and refining had nearly reached their maximum efficiency. Accordingly, chemists who sought a more satisfactory system of separation turned their attention to electro-metallurgy. Although this science was developed early in the nineteenth century by the researches of Davy and his disciple, Faraday, its practical applications were limited to the deposition of metals from their solutions by feeble currents generated by galvanic batteries.

In 1867, when Siemens and Wheatstone invented the dynamo-electric machine, the new era of electrolytic separation began. The utilization of mechanical energy for the purpose of generating continuous currents at steadily decreasing cost facilitated the use of electricity in metallurgical work. Within the next few years, Elkington succeeded in separating silver from copper by suspending bars in a solution of copper sulphate, electrolyzing the solution, and depositing pure copper on cathodes of wrought copper; the silver settled to the bottom and was recovered in the form of slime. Further improvements by Kiliani in 1884-5 fully established this process of refining blister copper, which has become universal practice for all except copper from Lake Superior.

E. Wohlwill, manager of the North German refinery, began experimenting in 1871 with the electrolytic separation of doré bullion. During the next four years he employed Gramme electric machines to supply current for decomposing an electrolyte of silver sulphate dissolved in hot sulphuric acid. Anodes of crude silver, containing a small percentage of gold, were rapidly decomposed, the silver being deposited upon platinum cathodes and the gold settling to the bottom. Wohlwill experienced so much difficulty in preventing the silver from falling from the cathodes and in checking the mechanical inclusion of particles of finely divided gold in the deposited silver, that he was compelled to abandon his interesting experiment.

In 1884 the Moebius system of refining doré bullion by electrolytic dissociation was devised. This process consisted of suspending anodes of silver-gold alloy in a weak solution of  $\text{HNO}_3$  and electrolyzing. The gold was recovered in bags encasing the anodes, while the silver deposited upon sheets of fine metal. Recently a slowly moving endless belt of sheet silver has been substituted for vertical cathodes. As the crystals of silver formed upon these belt cathodes they are conveyed out of the tank to brushes which remove the fine metal mechanically. The gold was further purified by boiling with nitric acid in porcelain pots. So successful did this process prove that a large Moebius installation at the American Smelting & Refining Co. plant at Perth Amboy, N. J., produced 24,000 oz. of fine silver per day in 1895. According to Mr. Borchers, the cost of refining, the actual materials, labor, fuel, and interest were reduced to ⅓¢. per ounce. Overhead charges were not considered. The Moebius process was found to give excellent results at a number of plants where base metals such as antimony, arsenic, sulphur, selenium, tellurium, bismuth, copper, and lead had been largely eliminated by oxidation in cupelling the bullion.

Early in the nineties the melter and refiner of the Philadelphia Mint, D. K. Tuttle, introduced the Moebius system at that institution with gratifying results. Gold was inquarted with silver and melted into slabs 18 in. long and 10 in. wide. These were hung from copper bars in solutions containing 1% of  $\text{HNO}_3$  and a little larger quantity of silver and copper nitrate. Twenty-one of these anodes were connected in multiple with 28 cathodes of sheet silver, and a current of 180 amperes at 90 volts passed through the electrodes. As the anodes decomposed during electrolysis the silver deposited upon the cathodes, while the gold, containing about one-tenth its weight of unparted

silver and insoluble base compounds, was held in muslin bags, and so removed when the operation was finished. A series of brushes moved by machinery scraped the depositing silver from the cathodes down to a submerged tray of cotton cloth which was removed at intervals. These operations were continuously conducted in 10 tanks of redwood, each being divided into 7 cells. The tanks were connected in series and the electrodes were wired in multiple. This plant produced 33,000 oz. of fine silver per day.

However well the Moebius process, and its modifications by Balbach and other electro-metallurgists, effected the economical and rapid refining of silver, the subsequent treatment of gold residue by boiling acids was deemed a drawback. A way of winning the gold directly by electrolysis had to be found. Wohlwill, who had first attempted to electrolyze doré bullion in a sulphuric acid solution of silver sulphate, turned his attention to the deposition of gold from the trichloride. He found that the fundamental principle of parting crude gold bullion electrolytically was the discriminating property of gold in uniting with nascent chlorine in the presence of free hydrochloric acid to form hydrogen gold chloride ( $\text{AuCl}_3 \cdot \text{HCl}$ ) or  $\text{HAuCl}_4$ . This complex gold anion migrates to the cathode where the dissociating force of the current evolves hydrogen, reduces gold, and forms hydrochloric acid, as shown by the equation

Electrolytic deposition of gold from cyanide solution in the Siemens-Halske process led to the conclusion that it could also be recovered from chloride solution. During the nineties, Wohlwill evolved his process. He found that bullion containing 93 to 94% gold could be economically refined by passing a current of comparatively high density through anodes of this alloy suspended in a warm solution of gold trichloride, mixed with about 5% of free hydrochloric acid.

Several conditions were essential to the successful operation of this process. If the silver present exceeded 5%, its chloride formed a protective coating over the surface of the anode which retarded decomposition in proportion to its presence in the crude gold alloy. Porcelain tanks were used as the parting vessels, heated over a sand-bath to a temperature of about 65°C. Current densities of 80 to 140 amp. per sq. ft. were passed through the cathodes of sheet gold; the higher the current density, the more loose and spongy the deposit. With a high current this difficulty was diminished by the addition of more gold chloride and hydrochloric acid to the solution. From 25 to 60 gm. of gold per litre of electrolyte was maintained by periodic replenishment with auric chloride. When the current density was lowered, Wohlwill discovered that increasing proportions of monovalent gold chloride were detached from the anodes and dropped into the slime. Experiments showed that the percentage of gold which dissolved at the anode but failed to deposit upon the cathode varied inversely with the current density. This had to be regulated with care to prevent the simultaneous deposition of base metal from soluble chlorides or the mechanical loss of gold from the cathode by the sloughing off of a too spongy deposit. Fragments of gold and aurous chloride dropping from the anodes, together with the tops, which hung above the solution, aggregated from 10 to 15% of the original weight of each anode which had to be recovered, remelted, and again refined. Silver settled for the most part as chloride into the slime, which was treated with zinc and sulphuric acid in separate tanks. Lead and other soluble chlorides remained in solution, particularly the platinum metals whose ready recovery was an advantage of this process.

A Wohlwill plant was built at the Philadelphia Mint in 1902. The results proved highly satisfactory, and the refinery produced gold of 999.8 fineness and silver almost 1000 fine. Copper contained in the crude alloy was recovered as fine electrolytic metal and used for coinage, while a notable recovery of platinum, iridium, and palladium was effected. D. K. Tuttle, in 1902, in reporting his progress with this process, said: "The ideal refining

plant would be one where two classes of bullion could be treated separately, blending to make up material for the anodes; one lot containing silver plus as much gold as could be worked by the Moebius process, the other being high-grade gold bullion for the gold trichloride system." After describing the low cost of generating the required current, he concluded: "Thus the energy of a few bushels of coal does the work of a dray of expensive acids." The deposition of 1 oz. of gold consumed but 10 watt-hours of electricity, and the equivalent weight of silver was carried to the cathode at a cost of 13.5 watt-hours. In the silver system a current density of from 20 to 25 amperes per square foot gave the best results.

(To be concluded.)

## Analysis of White Metal

A systematic outline of procedure for the analysis of white metal containing copper, antimony, tin, lead, iron, and zinc is given by R. Kopenhagen in *Ann. chim. anal.*, 17, 241-3. Two grams of alloy is treated with 30 c.c. of  $\text{HNO}_3$  (800 c.c.  $\text{HNO}_3$  plus water to make 1 litre) in a porcelain casserole, boiled and evaporated to dryness on sand bath; take up with 20 c.c. of  $\text{HNO}_3$ , letting stand in the cold for some time; add 25 c.c.  $\text{NH}_4\text{NO}_3$  solution (120 gm. per litre) and boil for 10 minutes, cool, filter, and wash (wash solution:  $\text{HNO}_3$  40 c.c.,  $\text{NH}_4\text{OH}$  30 c.c., water to make 1 litre). The precipitate contains stannic and antimonious acids with traces of Cu, Pb, and Fe; solution contains Cu, Pb, Fe, and Zn. Precipitate is washed into a conical 500 c.c. flask, a strong excess of  $\text{NH}_4\text{OH}$  added and  $\text{H}_2\text{S}$  passed through mixture. The  $(\text{NH}_4)_2\text{S}$  formed dissolves the Sn and Sb; after standing, filter on paper used with  $\text{SnO}_2$  and  $\text{Sb}_2\text{O}_3$ , wash with dilute solution of pale yellow  $(\text{NH}_4)_2\text{S}$ . The precipitate of CuS, PbS, and FeS on the filter is dissolved in a little  $\text{HNO}_3$ , + Br, Br expelled, and solution added to the first filtrate. The alkaline solution is evaporated to dryness on sand bath, taken up with 100 c.c. of  $\text{KClO}_4$  solution (50 gm. per litre), 35 c.c. concentrated HCl added and evaporated to dryness on water bath. Take up with 8 c.c. HCl, 150 c.c. water, and 25 gm.  $(\text{NH}_4)_2\text{C}_2\text{O}_4$ , heat to boiling, transfer to conical flask, and pass  $\text{H}_2\text{S}$  into solution for 2 hours, keeping temperature at 95°.  $\text{Sb}_2\text{S}_3$  precipitates with a small amount of CuX dissolved by the  $(\text{NH}_4)_2\text{S}$ , Sn remains in solution. To the almost boiling liquid add a little  $(\text{NH}_4)_2\text{SO}_4$ , shake, filter rapidly, and wash with a saturated solution of cold  $\text{C}_2\text{H}_2\text{O}_4$  charged with  $\text{H}_2\text{S}$  and containing  $(\text{NH}_4)_2\text{SO}_4$  and HCl; precipitate is put in beaker and treated with 20 c.c. of a 15% solution of KOH in alcohol; heat on water bath till sulphides blacken, and filter; all of  $\text{Sb}_2\text{S}_3$  is in KOH solution; it is re-precipitated by HCl in very slight excess and filtered off; wash with hot air-free water; re-dissolve in HCl plus a little  $\text{KClO}_4$ , evaporate to dryness on water bath, take up with HCl and water; add 5 c.c. of 40% KI solution, 5 c.c. of  $\text{CS}_2$ , and titrate with  $\text{Na}_2\text{S}_2\text{O}_3$  (41.33 gm. per litre - 1 c.c. = 0.01 gm. Sb). The Sn solution is boiled and electrolyzed. The solution containing Cu, Pb, etc., is heated to fumes with  $\text{H}_2\text{SO}_4$  and Pb determined as  $\text{PbSO}_4$ . To the filtrate from the  $\text{PbSO}_4$ , add 20 c.c. concentrated HCl and dilute to 350 c.c., boil, and precipitate CuS with current of  $\text{H}_2\text{S}$ , filter, oxidize filtrate, and precipitate Fe with  $\text{NH}_4\text{OH}$ , filter, re-dissolve  $\text{Fe}(\text{OH})_3$ , and determine iron volumetrically. Filtrate from  $\text{Fe}(\text{OH})_3$  is acidified with  $\text{HCO}_2\text{OH}$ , made feebly alkaline with  $\text{NH}_4\text{OH}$  and the Zn precipitated with  $(\text{NH}_4)_2\text{S}$ ; filter, ignite, and weigh as  $\text{ZnO}$ . To determine Cu, treat 2 gm. of alloy with 50 c.c.  $\text{HNO}_3$  (1:1), heat to expel nitrous vapors, dilute to 300 c.c., and electrolyze; the Cu is re-dissolved in 10 c.c.  $\text{H}_2\text{SO}_4$  + 20 c.c.  $\text{HNO}_3$ , diluted to 300 c.c. and electrolyzed; the Cu is re-dissolved in 10 c.c.  $\text{H}_2\text{SO}_4$  + 20 c.c.  $\text{HNO}_3$ , diluted to 300 c.c. and again electrolyzed and weighed. Results on alloy made in laboratory showed excellent agreement.

CERRO DE PASCO copper production for August passed the 3,600,000-lb. mark.

# Wolframite in Portugal

By F. BRONCKART

## GENERAL ASPECT OF THE WOLFRAMITE-BEARING ZONE

\*A granulite-schist massif occupies the northern region of Portugal which is bounded on the south by the Tagus, on the southwest by a tolerably straight line joining the confluence of the Rio Ocreza and the Tagus with Oporto and passing through Coimbra. In this region only are cassiterite and wolframite found in Portugal. The parent rock of tin is the granulite, and wolframite is one of the minerals associated with the cassiterite.

Generally speaking, the whole region is mountainous, but north of the Douro the country becomes more markedly broken. There a veritable labyrinth of mountains exists, the rounded tops of which attest their granitic formation and the action of long-continued erosion. On

FIG. 1. GEOLOGICAL MAP, PART OF NORTHERN PORTUGAL.

the west the mountains are cut by deep erosional valleys, but beyond the Rio Tamega, which separates Entre Minho and Douro from Tras os Montes, the country changes, the valleys become less deep, the schists, rare elsewhere, increase more and more, and beyond the peaks of Mogadouro the sad and monotonous, slightly undulating plain seems to stretch over the Spanish frontier into the plateau of Castille lying below, which was leveled in the Tertiary period.

## SUBDIVISIONS OF THE WOLFRAMITE-BEARING ZONE

The granulite-schist region may be divided in accordance with both its physical and geologic characteristics into three distinct zones:

*The zone south of the Douro.*—This fairly mountainous zone is formed by a granitic massif almost completely surrounded by Cambrian schists. It includes deposits of cassiterite and wolframite, in some of which one mineral occurs alone, and in others they occur together. One of

the wolframite deposits, that of Panasqueira, is worth mentioning here, because, situated in the schists and graywacke at a considerable distance from the granulites, it is unique in Portugal.

*The zone northwest of the Douro.*—This is an extremely mountainous zone. Almost everywhere the granulite outcrops, erosion having left only a few outliers of Archean schists. This zone is the richest of the three in wolframite-bearing veins. The latter are found everywhere in the contact of the schists and granulite, the mineralization seeming richer, however, in the granulite than in the schists. Cassiterite is found, either alone or accompanied by wolframite. The deposits of Boralha are by far the richest known in Portugal today. Those of Cerva, however, are also noteworthy and I shall have occasion to refer to them later.

*The zone northeast of the Douro.*—This zone, which is very hilly in the western part, develops toward the east into a plateau. Here the Archean schists cover the granulite almost everywhere, the latter showing only in a few outcrops. In the environs of Bragança, Mirandella, and Miranda do Douro, and in fact nearly everywhere, we find stanniferous veins with or without wolframite, at the contact of granulite and schist. Those in the environs of Miranda do Douro are well known as the Zamora deposits. In this zone few mines carry wolframite alone. There is one, however, at Iffanés, in which the wolfram-

FIG. 2. SHRINKAGE CRACKS AND ORE-SHOOTS.

ite shows a greasy lustre not common elsewhere, and which reminds one of the cassiterite of the region. The latter is found nearly everywhere in the vicinity.

## MINERALS ACCOMPANYING WOLFRAMITE

In Portugal, as throughout the Iberian peninsula, wolframite is found in quartz veins either alone or accompanied by cassiterite and almost always by pyrite, chalcopryrite, mispickel, and galena, and in many places also by tourmaline and fluorite. In very rare cases scheelite and tungstic acid are associates. I have found scheelite and tungstic acid only in the extreme east of the country, in the region of the classic tin deposits of Zamora, on top of a plateau cut in the schists. I have never found them in the mountains, which tends to prove that tungstic acid and scheelite are products of the superficial alteration of wolframite. Under such conditions they cannot be formed in the mountains where the waters do not stagnate and where they erode too swiftly to allow decomposition products to accumulate. Tourmaline is found everywhere—in the granulite, in pegmatite veins, and in veins of greisen and quartz.

## TREND AND MINERALIZATION OF THE VEINS

The wolframite has crystallized in stockworks, in vertical veins, fractures which are tolerably regular and relatively continuous and deep—and sometimes in horizontal veins at times very variable in direction, which are called entokinetic cracks and are produced by the contraction due to the cooling of the granulite. These cracks have been given the names 'shrinkage' cracks in granulite and 'desiccation' cracks in schists. There is nothing more capricious than these shrinkage cracks; their direction and their inclination vary greatly; they are also much faulted. And, as if that were not enough to baffle all calculations, the distribution of the wolframite in the veins is ever more capricious than the strike of the veins containing it. In

\*Translated by F. L. Hess from *Annales de la Société Géologique de Belgique*, 1908-1909, pp. B180-B191.

one place the wolframite appears as little brownish spots staining the quartz; in another there are rod-like crystals of varying size; but in most places the wolframite is not present, and one may dig long distances hoping in vain to see it reappear. Where the wolframite shows in spots there is likely to be continuity of mineralization, but this is a law to which there are as many exceptions as confirmations. With the rod-like form of fragments the wolframite is generally concentrated in pockets or shoots, but no law is known which governs the distributions of the pockets or shoots.

There is, in places, as in other mineral veins, an increase of mineralization where the thickness of the vein varies perceptibly, as at the faults, and at junctions with other veins; but in many places no variation of mineralization can be affirmed when the characteristics of the fissure varies. Inversely, it often happens that the mineralization decreases, increases, or even begins or ends without its being possible to affirm any variation in the character of the vein, either in the quartz which forms it or in the granulite which contains it. In fact, one can predict nothing as to the trend of the entokinetic fissures, nor as to the mineralization of the wolframite contained.

At other places in the Iberian peninsula, however, there are shrinkage cracks showing most beautiful mineralization and forming the richest wolframite-bearing veins. I hasten

FIG. 3. IDEAL CROSS-SECTION OF A GRANITE SCHISTOSE MASS WITH FISSURE VEINS AND SHRINKAGE CRACKS. ABOVE IS A MAP OF THE GRANITE-SCHIST CONTACT.

to add that sometimes the miner has the good fortune to find shrinkage cracks which, though not very deep, are tolerably long. Some extend several hundred metres, and I know of one that is more than a kilometre long. It is well known that with vertical veins there usually exists a relation, evidently varying considerably, between the depth of the fracture and its length, and that veins extending long distances are apt to be deep. This law cannot be applied to 'entokinetic' cracks, as for these it is of no value. I have represented in 1-1', 2-2', 3-3', 4-4', and 5-5' a few small lenticular cracks. (Fig. 2.) It is evident that their depth does not depend on their length.

#### THE CERRA DEPOSIT

The Cerra deposits are situated along the contact of the granulites and Archean schists in the eastern part of the zone northwest of the Douro, the general characteristics of which I have already described. All that I have said concerning the characteristics of entokinetic cracks and their mineralization is applicable here. I shall not, therefore, describe in detail these veins of Cerra, but I will cite among the different cases I have encountered those which seem to me particularly interesting, as well as some special characteristics of these veins.

Generally speaking, wolframite is found distributed almost everywhere in the mountains surrounding Cerra. Everywhere quartz lenses are found mineralized with wolframite, but their lack of continuity and their distance apart render them unprofitable. The north flank of Bentosellos, however, contains, in addition to such lenses, shrinkage cracks sufficiently important to admit of remunerative exploitation. Fissure veins and stockworks are also found.

As seen in Fig. 3, the granulite shows the characteristics of an intrusive. At their contact with the schists the schists have been but little modified by metamorphism, but they contain much mica. Often, as in stanniferous deposits, the granulite is transformed into kaolin.

#### GENERAL CHARACTERISTICS OF THE VEINS

The general features of these deposits may be summarized as below:

1. The fissure veins are more recent than the entokinetic cracks which they fault. These entokinetic cracks are more recent than the Archean schists into which they sometimes extend. The difference in the ages of the veins is impossible to determine.
2. The fissure veins are not so well mineralized as the entokinetic cracks.
3. The entokinetic cracks which extend across the con-

FIG. 4. RELATIONS OF VEIN TO OUTCROP.

tact seem to be less well mineralized in the schists than in the granulite.

4. The thickness of the entokinetic cracks is rather variable, but 0.30 m. (1 ft.) may be taken as the average. In some places it falls to 0.01 m. or 0.02 m. (0.4 of an inch, or 0.8 of an inch), and in numerous places it rises to 1.0 or 1.50 m. (3 1/3 to 5 feet).

5. I encountered, but rarely, veins of 0.01 m. to 0.02 m. mineralized throughout their thickness. On the other hand, in a case of enlargement of a vein whose average thickness of 0.30 m. (1 ft.) rose rapidly to 1.50 m. (5 ft.) I was able to isolate a massif of 11 cubic metres of vein containing a pocket, the end of a shoot, of 7 metric tons of wolframite. From this it was possible to separate free from gangue a block of wolframite weighing 165 lb. Above this pocket all mineralization ceased.

6. The average dip of the exploitable veins is about 30°, but, as I have stated, the dip varies a good deal.

7. Certain fractures (generally the longest) seem to follow the trend of the lines of level of the mountain. This trend has also been affirmed in other deposits, notably in the Erzgebirge, and seems to be structural. Erosion has acted but little where the veins appear, which is but a short distance from the schists.

## BLIND VEINS

A mineralized vein was followed a distance of 60 metres (200 ft.) until it disappeared. A cross-cut at a deeper point showed two thin veins, the second being the prolongation of that followed higher up by the drift. The first was unknown at the surface and in the drift. A little chipping done at the extremity of the gallery where the vein being followed had pinched, permitted the discovery and exploitation of another. Knowledge of the outcrops a, b, c, d, e, and f (see Fig. 4) led to the conclusion that the outcrops d and e were a prolongation of a, b, and c. Investigation showed that the fractures a, b, c, d, and e had throughout practically the same thickness and that wolframite absolutely free of pyrite, chalcopyrite, etc., had there crystallized into rich shoots.

On the contrary, fracture f, when followed about a hundred metres (325 ft.) showed a series of bunches where the wolframite, very rich in pyrite, chalcopyrite, etc., had crystallized into rich pockets. Everything seemed, therefore, to attest that d and e constituted a prolongation of a, b, and c, and that f was another vein without connection with a, b, c, d, and e. A cut made practically following N-N' at 1 to 1.5 m. depth did not reveal a vein. The vein which cropped out at f could, however, hardly have disappeared in so short a distance. What had become of it? A cross-cut was made to prospect the granulite at a little greater depth; and local conditions forced a north-south direction. Soon two small veins carrying wolframite and running east-west were cut. Drifts were run both east and west, and the east drift connected with the workings along a, b, and c, but in the west split into two smaller veins which did not reach the surface. The main vein was found to have been faulted and was picked up by a short incline (see cross-section *coupe* N-N). The vein did not reach the surface (cross-section M-M). These workings showed that they were on the prolongation of a-b-c, and that e-d-q was a different vein, although in direct line with a-b-c.

I have cited this instance not only because it is an example of a vein not outcropping at the surface, but more particularly because it shows how circumspect the engineer must be in his statements regarding trends and mineralizations as capricious as those of wolframite-bearing veins in entokinetic cracks.

## CONTINUITY OF WOLFRAMITE-BEARING VEINS

An interesting point is the continuity at depth of the veins formed in entokinetic cracks. It is often claimed that such deposits are superficial, and in proof it is stated that the shrinkage cracks are not prolonged to a depth of more than a few metres—which is true—and that consequently wolframite does not occur at depths beyond—which is false. Certainly the shrinkage cracks do not extend to great depth, but neither do they extend necessarily to the surface; that is to say, the shrinkage cracks that we see crop out are those that erosion has laid bare. Therefore, if we penetrate deeply, we should, at the same time that we see the exposed cracks disappear, discover new ones that do not appear at the surface.<sup>1</sup> (See Fig. 3.) This point is hardly open to dispute; unfortunately, if it cannot demonstrate that wolframite disappears with depth, neither does it prove the inverse, for there is nothing to tell us whether the new cracks we shall meet will be mineralized.

In this connection it is to be noted that the situation of the Portuguese wolframite-bearing beds in the granulite-schist zone shows that they are very often formed at the contact of granulites and schists. Wolframite originates from the granular magma and appears to crystallize near the periphery of this massif in contact with the schists that cover it. When erosion has been sufficiently great to carry off the schists and the adjacent wolframite-bearing zone, no more deposits will be found. This would tend to prove, then, that the mineralization of wolframite is effected in contact with schists on a more or less thick zone; that

is, that the wolframite-bearing veins are not prolonged into the granulites at great distance from contact with the schists. But this by no means proves that they are purely superficial deposits.

## The Laws of Crushing

A series of investigations on rock-crushing has been carried on at McGill University, and the consumption of power has been accurately measured for several standard types of crusher, working on different kinds of rock and crushing to different degrees of fineness. The result of these experiments is finally to disprove the law of crushing originally enunciated by Rittinger and accepted by nearly all authorities since his day, and to show that the more recent theory advanced by Kick is either true or so nearly true that it affords a close working approximation to the truth. Kick's law was originally stated in 1885 as a general theorem in mechanics, and it is only within the last few years that it has been applied to ore dressing, first by H. Stadler in South Africa, and more recently at McGill. It may be stated as follows: The power necessary to crush a given quantity of any given rock from any known size to any other known size, will be directly proportional to the reduction in volume of the particles; in other words, it will take almost three times as much power to crush 1-in. cubes to 1/2-in. cubes as to 3/4-in. cubes; or it will take twice as much power to crush from 1 in. to 1/4 in. as from 1 in. to 1/2 in. The McGill experiments were first directed to settling the question of the truth of the theory, and the results of a long series of experiments agree with the law to within the reasonable limits of error of experiment on so variable material as broken rock. Next the efficiency of a single crusher, say a Gates breaker, was studied over different parts of its range to determine whether it gave as high an efficiency when working from 4 in. to 1 in. as from 4 in. to 2 in. or from 2 in. to 1 in. Other crushers, such as stamps, rolls, and tube-mills, were similarly studied with a view to finding the most efficient range of each machine and the comparative efficiencies of the different machines. Obviously the amount of ground to be covered is enormous, especially as the experiments have to be carried out on a large scale, yet with the utmost care to eliminate errors. Therefore, only a small part of the work has as yet been completed, but enough has been done to justify the preparation of a preliminary report which is now being prepared for publication. It is believed that it will soon be possible to state with a considerable degree of certainty what type of crusher is most suitable for a given degree of crushing, and to state what output may be expected for any rock for which the confines have been determined.

## Mineral Production of China

There was no marked development of the coal-mining industry in China during 1911. The Chinese Engineering & Mining Co. mines produced 1,453,546 long tons compared with 1,174,312 tons in 1910; the Peking syndicate mines in Honan, 417,190 tons, compared with 357,209 tons in 1910; and the Hungshan and Fangtze mines in Shantung, 486,553 tons, compared with 482,880 tons in 1910. The Pinghsiang mines in Kiangsi, which produced 610,000 tons in 1910, closed down in October on account of the political disturbances. The Ching-hsing mines in Chihli are stated to have produced 600 tons per day during last year. The antimony refining works at Changsha purchased additional machinery, increasing the output of regulus from 100 to 390 tons per month, and further extensions are contemplated. The Chee Hsin Cement Co. plant at Tongshan, near Tientsin, installed new machinery last year. The capacity of the plant is now 500,000 bbl. per year.

THE present exact value of gold is \$20.671834625323 per fine ounce, according to the computation tables of the United States Geological Survey and the Bureau of the Mint. The average commercial price of silver in 1911 was 53c. per fine ounce.

<sup>1</sup>Very often float wolframite is found on top of mountains, although no quartz veins appear higher. The veins have been eroded.

## Fuel, Power, and Water Supply of Tonopah

By M. W. VON BERNEWITZ

A regular and cheap supply of fuel, power, and water for any mining district is essential, and in this respect Tonopah, situated in a Nevada desert at an altitude of 6300 ft., may be said to be fairly well provided. This and other mining centres in Nevada are much indebted to California for its oil production and extensive water-power development. It may be said, in fact, that Nevada is generally benefited by its neighboring state.

The use of coal under boilers at Tonopah is out of the question, as it costs about \$13 per ton, while coal for use in forges and private houses costs as much as \$19 per ton. Oil from California is used everywhere, on locomotives, under steam boilers, in heating drills for sharpening, in assay offices, and in smelting the precipitate from presses or zinc-boxes. As at other places where it is used as fuel, all manner of burners are in use; air and steam are used as atomizers, as also a new system whereby the oil is heated by steam coils to 250° F., and then pumped into the

ELECTRIC HOIST, TONOPAH MINING CO.

burner at 150 lb. pressure by an ordinary duplex pump. At the Montana-Tonopah mine, the oil used is 18° B., supplied by the Associated company. It comes by rail, in 12,400-gal. tanks, and is pumped to tanks above the plant, from which it is drawn off as required, and fed into the boilers at 140 lb. pressure. The monthly consumption of oil is 20,000 to 25,000 gal., 4500 tons of ore being treated per month. It is found that but little additional oil is consumed in winter. One tank of oil costs \$573, and the freight amounts to \$442, making a total of \$1015; the average cost to all mines at Tonopah being \$1.59 per barrel.

The Nevada-California Power Co. has four power-plants on Bishop creek, Inyo county, California, and supplies Goldfield, Tonopah, Millers, Silver Peak, Blair, Rhyolite, Pioneer, Manhattan, and Round Mountain, in Nevada. At Bishop, there are 10 Pelton and Doble water-wheels, direct connected to electric generators, current being produced at 2200 volts and stepped up to 56,000 for transmission 110 miles to these places. The water at the power-stations is used several times, and the average pressure is 470 lb. per square inch. From Bishop to Tonopah there are duplicate lines of copper and aluminum wire, and also a private telephone line. At Millers and Tonopah there are sub-stations, the latter containing seven 500-kw. transformers, and the usual switchboards and accessories. Power comes in at about 52,000 volts, is stepped down to 6600 for transmission to the mines, which transform it to 440 volts for motors. The daily power consumption at Tonopah is 70,000 kw. The main sub-station has been unfortunate of late, as two fires have occurred which will require the expenditure of nearly \$30,000 to replace the transformers and building. The Tonopah Mining Co. has an especially fine sub-station, which

consists of transformers, rotary converter, storage battery, switchboard, and automatic telephone exchange, and takes care of the peak-load at the various shafts and the Belmont mine also. I happened to be inspecting this plant at the time the second fire broke out at the sub-station; and it was interesting to watch the rotary converter automatically take up its load from the storage battery, which is sufficient to run the hoists for a short time, and the lights for about eight hours. Power is supplied to the Tonopah companies at an average of 1½c. per kilowatt-hour, based on peak or total loads. Everything, from hoists to pumps discharging vacuum filter-tanks, is motor-driven. Use of electric power gives flexibility; motors can be bolted down in any corner, and give little or no trouble.

The Nevada-California Power Co. is erecting two more power-plants, and has over 400 men at work. It is already supplying Riverside and San Bernardino, in California, a distance of 250 miles. Trouble with the transmission lines across the Mojave desert has been experienced. In this region there are eight steel towers per mile, supporting a thick aluminum wire with steel core. The wind gradually increases in velocity to 75 miles per hour, and the towers lift slightly on one side, letting sand under the foundation. This is reversed from time to time, and gradually the towers are lifted to a position where they are likely to topple over.

SWITCHBOARD AT SUB-STATION OF TONOPAH MINING CO.

Three additional transformers are also being added to the sub-station at Tonopah.

Fifteen miles north of Tonopah the Water Company of Tonopah takes its supply from a sagebrush country underlaid by gravel and sand. Here there are four shafts 6 by 8 ft., and ten 8-in. cased driven wells, 35 to 165 ft. deep, having a daily capacity of about 400,000 gal. There are three 65-hp. motor-driven Worthington pumps lifting the water through an 8-in. pipe to a reservoir of 232,000 gal. capacity, three miles from Tonopah. There is also an auxiliary steam-pump service for use when electric power is cut off, and the town and mines are never without full supply. At Tonopah there is another reservoir of 116,000 gal. capacity and two wooden tanks holding 45,000 gal. The average supply pressure is 65 lb., and the monthly consumption over 8,000,000 gal. Prices range from 75c. per 1000 gal., for mines, to \$1.25 for domestic use. Tonopah is, therefore, well provided for, and credit should be given to those who had enough faith in the district to provide the capital for the erection of plants for power and water supply.

RUSSIAN subjects have made 300 declarations for concessions to mine gold and asbestos in the Uriachaisk district of Siberia. Permits are being issued by both the Yenisei administration of state property and the district mining engineer. More than 2000 Russians already reside in this district, most of whom are engaged in the development of local mineral projects, and a general Russian colonization is rapidly taking place.

SEPTEMBER copper production at Cerro de Paseo was over 4,000,000 pounds.

# Amalgamation at the Homestake

By ALLAN J. CLARK and W. J. SHARWOOD

\*Inside amalgamation is practised at the Homestake mills, a copper plate  $\frac{1}{4}$  in. thick and either 5 or 7 in. wide being attached to the chuck-block under the screen of each mortar. The wider plate with high chuck is used with new dies, and the other is substituted as the dies wear. The outside plates are  $\frac{1}{8}$ -in. Lake Superior copper, in units 4 ft. 6 in. wide by 12 ft. long, though a few old plates of irregular length are still in use. One such unit of plain copper is placed immediately in front of each 5-stamp battery, and below it are two or three rows, usually wider, of silvered plates which are electroplated with 2 oz. of fine silver per square foot. At some of the mills, topography and other conditions have prevented the introduction of a plate system as complete as at the Amicus mill, and in others the grade and character of the ore treated have not warranted the addition of a fourth row. For instance, the Mineral Point equipment still consists of three rows of plates, each 4 ft. 6 in. wide by 12 ft. long for each five stamps. Wherever practicable the aim has been to increase the width of each successive row, and thus to thin the layer of pulp and facilitate contact of the finer particles of gold with the amalgamated surface. Mercury is fed to the battery hourly; the practice of inside amalgamation has been justified by assays of the tailing when using this system in comparison with outside feeding.

The loss of mercury per ton of ore varies in different mills from 0.06<sup>1</sup> troy oz. to 0.17 oz. The lower loss occurs in a mill crushing low-grade, thoroughly oxidized ore from near the surface, the higher loss prevailing in mills treating material containing more sulphides; a fair average is 0.13 oz. per ton crushed. If the loss of mercury in the different mills is compared with the corresponding weight of bullion obtained the variation is less, ranging between 0.6 and 1.1 oz. per ounce of bullion recovered, 780 fine in gold and 200 in silver. Attempts to correlate the loss of mercury per ton of ore with the area of plates per stamp led to no rational result.

The relation between the weights of mercury fed, total amalgam, and bullion for certain periods may be seen from the following table, the average ore representing that treated in the entire plant for a period of several months:

MERCURY FED AND LOST IN MILLS PER TON MILLED

	Average,	Low-grade		Fairly high-grade unoxidized ore,	
	oz.	oxidized ore,	oz.	oxidized ore,	oz.
Mercury fed to mortars <sup>2</sup>	0.30	0.27 <sup>3</sup>	0.20	0.33	0.364
Total amalgam obtained	0.55	0.30	...	...	0.80
Mercury lost in tailing.	0.132	0.085	0.09	0.17	...
Mercury found in precipitate:					
At slime plant .....	0.014	...	...	...	...
At sand plant No. 1.	0.001	...	...	...	...

The mercury finally lost, averaging 0.132 oz., amounts to about \$0.005 per ton milled. Much of the loss is probably due to conversion into sulphide by contact with pyrrhotite and arsenopyrite. The loss in retorting and melting is extremely small. A little is recovered incidentally in various places, sumps, cones, and launders. The slime plant

\*Excerpt from 'The Metallurgy of the Homestake Ore,' Bulletin 98, Institute of Mining and Metallurgy.

<sup>1</sup>Considerably lower losses are recorded for earlier times, when fully oxidized ores were treated, such as 0.04 oz. and less per ton. At these periods the plate area was considerably smaller than now.

<sup>2</sup>Additional mercury is sprinkled upon the outside plates, and a certain amount is also introduced during the cleaning of amalgam.

<sup>3</sup>In this case an additional 0.08 oz. of mercury was put on the outside plates.

precipitate has sometimes contained as much as 12% of its weight of mercury, but it has not been found profitable to attempt its systematic recovery. This mercury must have been dissolved by an extremely weak cyanide solution.

A test in the Golden Star mill showed that an average of  $\frac{1}{4}$  troy oz. of mercury is required per square foot to 'set' copper plates newly coated with 2 oz. silver per square foot before commencing amalgamation. If allowed to stand for any considerable time before using it is probable that more mercury would be necessary, as it is slowly absorbed and the surface hardens. The amount daily sprinkled on the plates varies with the condition of the plates and the character of the ore.

In using silvered plates the best results are obtained when the amalgam is kept moderately soft, and it is found that the best conditions are maintained when the temperature of the mill water is kept constant at about 50°F. The tendency of a higher temperature is to render the mercury more mobile, so that much of it separates and trickles down the plate, finally lodging in the traps at the foot of the tables. The amalgam left tends to become hard and is difficult to remove from the plates by the usual methods until cooler weather again prevails. When this occurs the plates resume their normal condition, and the yield may then be, for a few days, several times the amount ordinarily recovered. This condition is the only instance of 'accumulation' of amalgam noted here, and its temporary character is indicated by the abnormal recovery for a brief period after the return to regular conditions. The 'absorption' of amalgam by plates is almost negligible, as will be shown later. The following comparison shows the effects of dressing the silvered plates oftener than once in 24 hours:

COMPARISON OF RECOVERY FROM SILVERED PLATES (THREE ROWS) WHEN DRESSED ONCE AND TWICE DAILY.

	Twice daily.	Once daily.
Second row .....	\$491	\$451
Third row .....	240	248
Fourth row .....	120	128
Total recovered from silvered plates...	\$851	\$827
Relative value .....	100	97.2

The values given in this table are the totals for the amalgam obtained during several different periods. The differences from period to period were in some cases very small, and in some cases there was a slight difference in the opposite direction to the averages given above. The general tendency, however, as evident in the averages, is to catch rather less on the upper plate, when it is dressed too often, but a little more on the last two plates—presumably owing to the larger amount escaping from the upper one. During four months, May-August, of 1910, the general recovery by amalgamation was 72% of the total ore content; at the Lead mills during the same period it was 74%. It is noteworthy that the unoxidized ore from the lower levels yields about as high a percentage of its gold by amalgamation as the fully oxidized ore from the open cuts and shallower levels. On the other hand it must be remembered that the open cut ore now being worked is of low grade compared with that formerly mined near the surface, which is stated to have yielded a higher percentage, the tailing being of low value although no secondary treatment was practised.

A certain number of the chuck-blocks in each mill are changed every day, and the amalgam is then scraped from the inside plates, thus making the entire round of the mill in 15 or 16 days. The outside plates are cleaned up once a day, except those of the lowest row, which are cleaned up on alternate days. Amalgam is removed from the first row plates by brushing with a small whisk broom, that on the lower plates is swept up with a long-handled floor broom of stiff straw. No violent methods, such as steaming or scraping with steel tools, are used on these plates. In each mill the amalgam from the mortar, and from each outside plate, is separately cleaned and weighed daily. Warm water is generally employed before squeezing it. The skimmings are worked up every ten days by grinding in a barrel. At

the foot of certain row of plates are traps, from which the sands are daily removed. These 'trap sands' are run each day over a special silvered plate, and the amalgam thus obtained is cleaned up every ten days.

The amalgam traps are simple boxes or shallow troughs, placed at the lower end of certain plates and running completely across the tables. They contain no baffle plates or amalgamating devices, and are cleaned up by removing the accumulated heavy sand with a scoop and carrying it in buckets to a box, from which it is sluiced over a plate.

An experiment was made on two pieces of copper which had seen long service in catching amalgam, one a worn-out plate from the chuck-block of a mortar, the other a discarded plate from the first row, not silver plated. After being cleaned by the usual mill procedure, and without violent scraping, each was set in a planing machine and a series of the thinnest possible slices were planed off, each

HIGHLAND HOIST, HOMESTAKE MINE.

of which was weighed and separately assayed. The results may be briefly stated as follows:

SUMMARY OF ASSAYS OF LAYERS PLANED FROM OLD MILL PLATES.

	Chuck-block plate.	Outside plate.
Original thickness of copper, in. ....	0.250	0.125
Worn down to, in. ....	0.120	0.091
Percentage of total gold contents found in layers next surface, totaling about $\frac{1}{64}$ in. ....	98%	98%
Gold contained per sq. ft.:		
Value .....	\$1.11	\$0.31
Ounce .....	0.054	0.015
Area of entire plate, sq. ft. ....	2.5	54
Gold in entire plate:		
Value .....	\$2.80	\$16.75
Approximate ounce .....	0.135	0.81

In each case, beyond a depth of 0.005 in. from the face, nearly all the gold content was in dents and pinholes. In addition to the amalgam on the face, the outside plate showed on the back a few extremely thin patches of films and amalgam, which had evidently worked round the edges. Silver was not considered in the calculations, as the plates were both of old copper, not electrolytically refined, and the original silver content was unknown. It is evident that the accumulation of precious metal on plates does not go on here to anything like the extent reported from some other mills, where amalgam has been allowed to build up to a considerable thickness. Possibly this difference is due to the relatively low grade of Homestake ore. The fact that practically all the gold carried by an old amalgamation plate resides at the surface is also proved by the work of R. H. Richards on a plate from a Nova Scotia mill. Our experiments were made before reading his statement, and were prompted by the extreme differences of opinion prevailing among millmen with whom the subject was discussed, which ranged from the impression that no penetration whatever took place to the idea that a plate of Lake Superior copper would be converted, by a few years' use in a mill, into a literal pseudomorph of solid amalgam. An

experiment made some years ago is perhaps worth recalling, although the exact data were unfortunately not all placed on record. A plate of sheet steel was coated with copper by electro-deposition, and then silver was deposited to the usual thickness—2 oz. per square foot. This was placed in the second row of one of the mills, where the coating lasted fully two years, and in behavior it could not be distinguished from the silvered copper plates running parallel with it.

In connection with the copper-plating of steel another departure may be noted. It is well known that when copper mill plates are fastened to the wood tables or sluices by steel nails or screws, the heads of the latter are rapidly attacked by electrolysis and rust off. In some mills, using relatively narrow tables, this difficulty is overcome by using wood cleats at the sides to retain the plates. With very wide tables this is impracticable, and in the Homestake

LEAD, SOUTH DAKOTA, SHOWING HOMESTAKE MILLS.

mills solid copper nails or spikes have been long in use, the heads becoming amalgamated at once, like the plate itself. These, however, are difficult to draw when re-plating becomes necessary, so that plates are often bent in the process of removal. Steel screws were therefore electro-plated with copper, starting with a cyanide solution and then using the sulphate as electrolyte. The heads of these become amalgamated in the mill, but the metal is protected, so that they can be unscrewed after over two years' use. They promise to be a cheap and effective substitute for the copper nails.

Three times per month the whole of the amalgam obtained during the preceding ten days is brought to the assay office, and the weight reported from each individual mill is verified by weighing to 0.1 oz. The amalgam is put into cast-iron trays, which are placed in horizontal cylindrical retorts, and covers are luted and keyed on. Each of the five retorts will hold 7000 oz. of amalgam. The fires, of pine wood, are started about 3 p.m.; about an hour later mercury begins to flow from the water-jacketed condensers, and the fires are kept up as long as this continues. About 8 a. m. next day the retorts are opened, the crude bullion is taken out, the product of each mill is weighed to the nearest ounce, and the whole is divided so as to give bars of about equal size, not exceeding 2000 oz. troy.

The bullion is melted in No. 50 graphite crucibles, in coke furnaces;  $\frac{1}{4}$  lb. of pulverized borax crystals is added to each pot. With four furnaces, four bars, worth nearly \$130,000, can be thus melted at once, but if the amount exceeds this it is necessary to use one or more No. 100 crucibles, from which two bars can be poured at one heat. As soon as the metal is set, a little water is poured on the top to partly chill the slag, which is then pulled or scraped off with a hook. The bar is then turned out, picked up with grip tongs, and plunged into a bath of very dilute nitric acid, then in cold water, and scoured with wet sand. It is then rinsed, dried, sampled by drilling two opposite corners, stamped with a consecutive number, weighed to 0.1 oz., and stamped with its weight and, finally, sacked, and delivered to the United States Assay Office. The loss in melting the crude bullion is about 0.66%; in re-melting the finished bars at the United States Assay Office there is a further loss of about 0.04%.

## California Miners' Association Meeting

The sixteenth annual convention of the California Miners' Association was held in Native Sons' hall, San Francisco, December 9, 10, and 11. Though nominally the sixteenth session it is not so in fact, since no meeting has been held since 1906. The convention was called to order on the morning of December 9 by W. C. Ralston, the president, who outlined the topics for consideration. In the afternoon session A. J. Wallace, lieutenant-governor of California, spoke on behalf of the state and urged the appointment of a committee to confer with federal and state authorities. A. A. d'Ancona made a brief address of welcome on behalf of the Mayor of San Francisco and M. H. De Young, on behalf of the Directors of the Panama-Pacific International Exposition requested the cooperation of the Association in securing exhibits for the exposition. C. F. Curry, congressman-elect, spoke of legislation and the mining industry; J. A. Britton discussed hydro-electric power as a factor in mining; Whittan Symmes described the work in progress on the Comstock Lode; and Terey L. Ford briefly reviewed the history of the Association. The chairman then announced the following appointments on committees:

Order of business—B. M. Newcomb, chairman; S. W. Cheyney, H. L. Slosson, Jr., Ed. H. Benjamin, J. R. Tregloan, E. J. Rector, Frank W. Street, S. B. Christy, J. J. Hamlyn, H. C. Cameron, M. B. Kerr, B. C. Clark, W. J. Graham, Elgin Stoddard, A. B. Ruggles.

Resolutions—Charles M. Belshaw, chairman; A. H. Ricketts, F. R. Wehe, Frank A. Leach, W. F. Englebright, A. E. Boynton, Frank H. Short, A. J. Pillsbury, Russell L. Dunn, S. B. Christy, H. Foster Bain, F. T. Nilon, Louis Rosenfeld, E. C. Voorheis, Clarence M. Oddie, J. H. Miller, George B. Finnigan, C. C. Derby, George Scarfe, Robert J. Strang, Charles Grimes.

Mining exhibit at Panama-Pacific International Exposition—N. Cleaveland, chairman; E. B. Braden, W. H. Storms, Thomas T. Read, Henry Gould, J. N. Nevius, J. Schwarzechild, E. H. Franklin, W. W. Waggoner, W. W. Coe, James F. Farragher, A. C. Hoofer, Adna Lamson, L. L. James, M. Blumenkrantz, E. C. Hutchinson.

The session on Tuesday was opened by the reading of a paper on public land administration, prepared by W. C. Mendenhall and read by C. G. Yale, in the absence of the author, which will appear in our issue of January 4. To this presentation of the matter from the viewpoint of the federal authorities, A. H. Ricketts replied from the standpoint of the mining industry, in part as follows:

Previous to congressional legislation relative to conservation the federal statutes affecting the disposal of public lands provided for the divestiture of the government's title to the public domain as, for instance, to a state for educational purposes, to a transcontinental railroad in aid of its construction, as bounty to those who have been its defenders in times of war, to the settler upon such lands, and to the mineral claimant.

The basis of the conservation policy of the government is to retain the title to public land in the United States, permitting its use under a lease or permit, when the bureaus choose to issue one, except that, as in the case of forest reservations, the mineral claimant may still locate and patent mineral claims therein under the federal laws and appropriate water rights under the state law.

The vesting of administrative authorities in relation to governmental reservations tends to render vested property rights therein commercially valueless by depriving the miner of the means of its exploitation and the reduction of his ores by denying him access to water within or necessarily conducted across reserved land, and to take away an essential use of property is to take the property itself. This unsatisfactory condition arises from the manner in which the laws are administered by the federal departments, which are persistently exceeding their limited lawful power over the public domain.

At the afternoon session A. J. Pillsbury, chairman of the

State Industrial Accident Board, presented an especially able and interesting discussion of the theory of employers' liability and workmen's compensation, and outlined the legislation necessary to bring the law now in force in California into such shape as to be less oppressive to the employer and more serviceable to the workman. The legislation on this topic which has been enacted in other states and territories was then reviewed by F. T. Nilon.

At the morning session on Wednesday, addresses were made on conservation and workmen's compensation. F. N. Short opposed federal control of natural resources, and A. C. Baker, director of exhibits of the Panama-Pacific International Exposition, outlined the considerations which should govern the preparation of a mining exhibit and asked the cooperation of the members of the Miners' Association in securing an adequate exhibit for 1915. At the afternoon session, W. W. Waggoner discussed the conservation of flood waters in hydraulic mining and suggested that hydraulic areas might be used as storage reservoirs, since good sites in the Sierras are scarce, at high altitudes, and are usually inadequate. F. E. Brooks recited a stirring poem on California, which has been accepted by the Exposition authorities. A number of papers on interesting topics, which had been arranged for, were not presented for lack of time, the discussions on workmen's compensation and conservation having been unduly protracted.

The present officers, William C. Ralston, president; Charles H. Dunton, vice-president; John Henry, treasurer; and John R. Tyrell, secretary, were reelected for the ensuing year. Resolutions were then adopted providing:

That the Association meet in San Francisco during October, 1915.

That the state undertake accident and liability insurance.

That the Los Angeles Chamber of Commerce be commended for its efforts to prevent fraud in the flotation of mining ventures.

That permanent headquarters for the California Miners' Association be secured in San Francisco, with a paid officer constantly in attendance to give information to visiting mining men in regard to the purchase of equipment, and the securing of competent employees.

That the state legislature be asked to appropriate \$25,000 "to examine any fake or wild cat organization" and to bring it to the attention of the attorney-general, or the post-office authorities.

That increased appropriations should be made by the state for the work of the State Mining Bureau.

That the Association cooperate with the officials of the Panama-Pacific International Exposition in securing an adequate mining exhibit, and that a committee consisting of one representative from each county be appointed for that purpose.

The following resolutions concerning the public land question were also passed:

*Resolved*, That the attention of Congress is called to the persistent and harmful interference of federal bureau officials with the operations of prospectors and miners who go on the public land to mine under and by virtue of the unrepealed and unmodified grants heretofore made by Congress to citizens, of free minerals, free timber for mining, free mining, and free occupancy of the public land containing minerals, and Congress is hereby asked by its appropriate action to abate this harmful interference of administration officials of the Federal Government with citizens engaged in peaceably and lawfully mining on the common public land of all the citizens of the United States.

*Resolved*, That the president and secretary of this association be, and they are hereby, directed to transmit copies of the foregoing resolution to senators and representatives of the state of California in Congress and to the governors of the several states of the union.

*Whereas*, The public lands were ceded by the original states of the Union to the Federal Government, to be held in trust and to be disposed of to actual settlers as soon as could be done and at reasonable prices; and

*Whereas*, The later states admitted to the Union have been

admitted upon the same understanding and upon an equality with the original 13 states; and

*Whereas*, This rule is embodied in the early acts of Congress and in many decisions of the Supreme Court of the United States; we therefore believe that the remaining public lands in all of the states should be disposed of consistent with this policy and to actual settlers, where suitable for settlement, and where unsuitable for settlement that the same should be disposed of or devoted to the most beneficial use of mining or other uses to which they are suited, to the end that all of the public lands shall be, as soon as practicable, devoted to actual settlement or to the most useful available purposes, that the states may be fully settled and their resources fully developed as soon as can be done for the benefit of the people of the several states, and therefore for the benefit of the whole people of the United States. And we are opposed to any policy in any direction inconsistent with this equitable rule and the understanding in connection with which the United States holds and administers the public lands. We call upon the governors and the legislatures of the several interested states to see to it that the rights and interests of such states and of the people shall be properly guarded and fully protected.

*Resolved*, That the attention of the governor and legislature is hereby called to the persistent interference of Federal bureau officials with the use of the water of the streams of the state by miners, and the appropriate action of the governor and legislature is hereby asked to abate this Federal bureau interference with the free and full enjoyment by the miners of their property rights in the use of the water of the streams under indefeasible grants of proprietary title by the primary owner thereof, the state of California.

*Resolved*, That the law committee of the California State Miners' Association prepare and transmit to the governor and legislature its report on the primary title to the water of the streams in California and on the incidents or property rights attached to such primary title.

*Resolved*, That the president and secretary of this Association be, and they are hereby, directed to transmit copies of the foregoing resolutions and the report of the laws committee of the governors of the other states of the Union.

The Association then adjourned to meet in October 1913.

THE annual dinner of the Broken Hill section of the Australasian Institute of Mining Engineers was held at Broken Hill on October 22, there being 100 members present. Mr. George Weir, of the North mine, stated the following with regard to silver, lead, and zinc production of that important centre: "During the past few years the greatest metallurgical development has been in the extraction of zinc. In 1904 the value of zinc concentrate produced amounted to \$275,000. In 1911 the production had increased to 516,000 tons, valued at \$5,610,000, making the value of the total production from all the Broken Hill mining and treatment companies of silver, lead, and zinc for the past year approximately \$24,000,000. The total value of Broken Hill mineral production to the end of 1912 may be estimated at \$340,500,000, which is practically equal to one-third of the total value of the entire mineral production of New South Wales from its foundation in 1788 to the present day. In addition, the value of Broken Hill current production represents more than 50% of the entire mineral production of the state. Therefore, Broken Hill takes premier place in the mineral industry in New South Wales. Within the state one person out of every 43 is directly employed at mining, and if allowance is made for other industries and businesses dependent on mining, together with wives and families, there is probably one person in every 15, or, say, 7% of the population of the state engaged or dependent on the mineral industry. In regard to the extent of mineral wealth, the large production of gold, silver, copper, lead, zinc, and tin, the extent of the coal deposits, the presence of large quantities of iron ore, and the great variety of minerals found in appreciable quantities, suggest that the future history of mining will in all probability be more remarkable than that of the past."

## Bureau of Mines and Western Mining

By J. A. HOLMES

\*The people of the country are coming slowly to recognize the fact that, of its two great foundation industries, mining, no less than agriculture, is entitled to the recognition and aid of the Federal government. And it is to be hoped that they will also soon come to recognize the fact that the mining industry of the Western or public-land states is entitled to special recognition and aid, because of the fact that these lands belong so largely to the Federal government, and are, therefore, not taxable by the states for the support of local expenditures.

Under modern conditions no country can become great or can maintain its greatness without the aid of a mining industry, which furnishes its supply of coal and oil and iron and steel and other essential mineral materials. And it should be kept in mind that while a country may increase its agricultural resources by the improvement of its soil through the addition of fertilizer and water, of mineral resources it has but the one supply, which it cannot increase but must decrease in proportion to both as this supply is used and as it is wasted or destroyed. It is true, therefore, that the benefits which a country may receive from its mineral resources will depend not only upon the nature and extent of those resources, but also upon the intelligence and wisdom with which they are developed and used.

With the opening up of the Panama canal, the United States will enter upon a new era of commercial development which will call for far larger export of coal than we have ever estimated in the past. And we should see to it that this export of raw materials develops also large imports of mineral as well as of agricultural products; so that the ultimate results may be thoroughly beneficial to American industry. In this connection, as well as in other connections, we may realize the fact that the most important function of a national Bureau of Mines is not simply to facilitate or hurry up the development of mineral resources, but to aid in bringing about the most efficient and the wisest development of these resources.

Both the Secretary of the Interior and the Director of the Bureau of Mines have been yearly urging Congress to provide the Bureau with appropriations for mining investigations in the Western states, and on a scale commensurate with the importance of the mining industry in these states. The investigations of the mine disasters in the coalfields of the Middle and Eastern states have required a large part of the energies and the appropriations of the Bureau of Mines during the first two years of its existence. But Congress has recently granted an appropriation of \$50,000 for the inauguration of special investigations in behalf of the Western mining industries, and the Department has recommended that for the next fiscal year this appropriation be increased to \$250,000. The Bureau now has under way an investigation into the California petroleum industry; an investigation looking to the use of crude petroleum as a means of facilitating the electric smelting of iron ores; and an investigation looking to the improvement of smelter conditions. If Congress grants the larger appropriation which the Department has asked for, it is expected that the Bureau's investigations will be considerably enlarged. As to the work to be done, and as to the manner in which these investigations may be carried on to the best advantage, the Directors of the Bureau of Mines will welcome suggestions.

NAGAOKA dispatches to the *Nichi Nichi* state that No. 1 well of the Nippon Kerosene Co. at Nishiyama, Japan, suddenly gushed oil on September 19, 450 koku (1 koku = 39.70 imperial gallons) being blown out in 15 hours, which is a record quantity in Japan. The kerosene market in Echigo has since acquired an unusual activity.

\*Abstract of letter sent to Sixteenth session of the California Miners' Association.

## An Internal-Combustion Oil-Engine

By W. S. NOYES

The Presidio Mining Co., operating a silver pan-amalgamation mill at Shafter, Texas, recently installed an internal-combustion oil engine with the following actual results in operating economy.

The engine formerly used is a 16 by 36-in. Reynolds-Corliss heavy-duty pattern of 115 bhp.; the oil-engine replacing it is a 20 by 34½-in. De La Vergne Machine Co. type 'F.H.', of 130 bhp. The oil used is Texas crude, 0.927 specific gravity, or 324.66 lb. per barrel.

### COMPARISON OF FUEL CONSUMPTION

Engine.	Lb. Oil per Bhp.-hr.	Ratio.
De La Vergne .....	0.425	1.0
Corliss .....	2.882	6.8

The De La Vergne engine was guaranteed to consume not over 0.6 lb. oil per bhp.-hr.; but, as shown by the above, its fuel consumption is practically 30% less than the amount called for by the guaranty.

### COMMERCIAL ECONOMY

The process in use at the mill requires heating of the amalgamating pans by steam through their steam cones. This was formerly done by the exhaust from the steam-engine. After the installation of the oil-engine, live steam was required for this purpose; hence the oil consumption of the new plant is as follows:

	Lb. Oil per Bhp.-hr.	Ratio.
De La Vergne engine.....	0.425	...
Heating pans referred to bhp.-hr.....	0.325	...
Total .....	0.725	1.00
Corliss engine .....	2.882	3.85

At the present cost of oil, the saving effected by the oil-engine is \$44 per day if running full time.

The De La Vergne engine is of substantial and heavy design, and of the highest grade of material and workmanship. It runs without any difficulty from 98 to 99% of the possible time, and such delays as have occurred were not from any defects in the machine itself, but rather from small troubles with the auxiliary, or oil-feeding, mechanism. The spray valve is easily stopped up by the carbonizing of oil or any slight sediment in the oil if the latter is not very carefully strained. The delays at Shafter were from the above-mentioned spray valve and little defects with the air-compressor and its valves. All these causes are difficult of detection except by experienced men, and men with such experience are difficult to obtain, particularly in the frontier districts. A short statement of the condition is that such engines have developed much more rapidly than men to operate them.

A CHINESE SYNDICATE with headquarters in Ipoh, Federated Malay States, and ramifications throughout Malaysia, is reported to have obtained a mining concession to prospect for all kinds of minerals over the entire province of Fukien, China, for the space of two years. The capital is \$1,000,000. The prospectors sent up to China some years ago have, it is stated, returned with rich samples of silver ore, and others are now proceeding to Fukien to verify the reports.

THE world's production of gold in 1911 is estimated at \$167,449,600 by the U. S. Geological Survey. Africa was by far the greatest producer, with \$192,972,100; the United States came second, with \$96,233,500; Australasia third, \$59,187,900; and Mexico fourth, \$29,196,000. Other large producers were Russia and Finland, \$24,865,000; China, \$10,000,000; British India, \$10,463,200; and Canada, \$9,762,100. South America as a whole produced nearly \$17,000,000.

## Recording Gauge for Filter Operation

STAFF CORRESPONDENCE

The scheme of treatment at the Montana-Tonopah filter plant involves dumping 150 tons of ore per day into a steel ore-bin, from which it is drawn out, crushed by a No. 5 type K Gates, elevated to a revolving trommel, and the oversize reduced to 1¼ in. by two No. 3 type D Gates machines. A 14-in. belt conveys the broken ore to the mill-bin, from which it is fed to forty 1100-lb. stamps, crushing through 20 to 25-mesh screens in hot cyanide solution. There is about 3% of pyrite in the ore, and nearly one ton of concentrate is caught daily on 8 Wilfley tables. This is dried to 5% moisture and shipped to smelters. Pulp from the concentrators is lifted by two bucket elevators to two Dorr classifiers, which work in the closed-circuit system with two 5 by 22-ft. tube-mills. The classifier overflow goes to three settlers or dewaterers. Thickened slime is then pumped to six Hendryx and one Trent agitators for

52 hours' agitation in a 5-lb. cyanide solution. Live steam is introduced here and the temperature kept to 110° Fahrenheit.

The vacuum filter plant consists of two filters with 100 leaves in operation, each 5 by 10 ft. The chart reproduced is a complete record and check on the work done in this department. The Montana-Tonopah mill is at an altitude of about 6500 ft., and the possible vacuum is 22 in., while from 18 to 20 in. is maintained during filtration. A study of the recording gauge shows, for instance: At 7 p. m. the filter tank was filled with slime, and formation of cake started, the vacuum keeping at 5 in. for about 25 minutes, then rising to 18 in., remaining steady at this for 60 minutes, when the cake was formed, and excess slime pumped out by a centrifugal pump to the stock tank. From 9 p. m., when the tank was filled with weak solution for washing, the vacuum averaged 18.5 in., dropping momentarily to 16.5 in. at 9:50 p. m., until at 10:35 p. m., when treatment was finished, suction ceased, and the cake was blown off and discharged. The complete cycle, therefore, was 3 hours and 35 minutes. Silver and gold are precipitated by zinc-dust, supplied by an adjustable feeder, which also has an arrangement to prevent the dust from setting hard during feeding. An extraction of 93% is obtained at a total cost of \$2.99 per ton.

BULAWAYO is about to have a new producer. This is the Redrup's Kop mine, situated 12 miles from Bulawayo and controlled by the Forbes Rhodesia Syndicate. The property has been equipped with a 5-stamp mill and a 5-ft. Chilean mill, with sand and slime plants of a minimum capacity of 25,000 tons per year.

## Discussion

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment. Insertion of any contribution is determined by its probable interest to the readers of this journal.

### A Treatment Problem

The Editor:

Sir—In your issue of November 16, Henry Vogel makes inquiry regarding cost of treatment of accumulated silver-bearing tailing derived from patio or other processes, and carrying about 8 oz. silver per ton. He refers to dumps of such material, aggregating 600,000 tons, scattered over the province of Junin, Peru. Presumably the physical condition of the tailing as to cleanness, location, size of individual dumps, accessibility, questions of water and power will have important bearing on costs, aside from metallurgical considerations. The conditions assigned by Mr. Vogel, namely 80% passing through a 200 mesh, silver content 8 oz.,  $\text{SiO}_2$  80%,  $\text{Al}_2\text{O}_3$  1.7%,  $\text{FeO}$  7.7%, and a fairly large amount of mercury present, do not, therefore, present the problem fully enough to prevent a comprehensive and categorical reply.

I spent about three years in the testing and treatment of a large old dump of silver-bearing tailing at Cortez, Nevada, containing 100,000 tons of material and carrying about 8 oz. of silver, with a little gold. The ore had previously been roasted and treated by thiosulphate. Owing to faulty lixiviation washing methods, about half of the metal content of the tailing was readily soluble in weak cyanide solution, enough more to make up an 80% recovery, which seemed to be the maximum possible, was extremely difficult to get into solution with a reasonable cyanide loss. Finally, no attempt for a high recovery was made and attention was concentrated on operating methods, to reduce the cost to the minimum. Owing to the cost and uncertainty of labor in districts away from the railroad, and numerous other resulting factors, our costs were excessive, but inasmuch as these still permitted a profit, operations were fairly satisfactory. Much preliminary testing was done by the California Ore Testing Co., and the results attained in treatment of about 30,000 tons were closely anticipated by these tests. The general scheme of treatment was by rapid leaching, using a large total volume, as much as 5 to 1 of solution, of low strength, 0.2 to 1 lb. per ton. Excessive alkalinity aided solution and precipitation results, and about 15 lb.  $\text{CaO}$  per ton tailing was added. The extraction ranged from 45% to 55%, averaging 50% and the costs on about 15,000 tons treated, at the rate of 80 tons per day, were very closely as follows:

	Per ton.
Labor .....	\$0.34
Solution men .....	0.14
Superintendence .....	0.08
Cyanide, $\frac{1}{2}$ lb. at 22c.....	0.22
Zinc shaving, 0.4 lb. at 15c.....	0.06
$\text{CaO}$ , 15 lb. at 1c.....	0.15
Gasoline power .....	0.06
Marketing bullion .....	0.05
Depreciation and amortization.....	0.20
Supplies and petty cash.....	0.05
	<hr/>
	\$1.35

Many physical difficulties, owing to adverse operating condition, were encountered in the treatment of the tailing. It was found most essential to change the stock solution completely every month or two, owing to fouling by soluble impurities in the tailing. On using fresh solution, good results were always obtained with little trouble, but after use for several weeks the fouled solution gave much trouble, in precipitating principally. This was the only important metallurgical difficulty.

A. W. GEIGER.

San Francisco, December 3.

### Mexican Conditions

The Editor:

Sir—With reference to certain remarks and opinions of G. L. Sheldon regarding the Monroe Doctrine—which opinions seem to be shared by many—appearing under the heading 'Mexican Conditions' in your discussion column of November 23, permit me to express myself somewhat emphatically on a subject so greatly misunderstood by both North and South Americans alike.

In order to make it clear that I treat this subject from an international point of view and that I speak in the interests of all, I may mention that I am a *porteño* of Argentina; in other words, I was born in Buenos Aires, where my late father was for half a century one of the leading German merchants and where we still have large interests. My cousin conducts a similar house in Montevideo and an uncle was equally active as an international merchant in Rio de Janeiro, where I spent some time, as likewise in the West Indies and all over Mexico. I may also mention that I spent twelve years in France and Germany before taking up my studies in the United States and becoming an American citizen by choice. All our mining operations in Mexico, in the interest of French, English, and German capital, had to be abandoned with considerable loss and a 10,000-acre coconut *hacienda* near Acapulco, owned and operated by several members of my family, was completely destroyed by 80 bandits, one of our nephews murdered by them in cold blood, and everything movable carried away. Indeed I might feel justified in condemning the American policy, but such is not the case. There is a great difference between selfish pocketbook patriotism and true regard for the welfare of your neighbors. I can find no fault with the Monroe Doctrine with regard to South America, but I do find fault with the Americans who go to South America.

When President Monroe established the doctrine of foreign non-interference on the American continents, he proved himself a far-sighted statesman. If it were not for this doctrine, South and Central America would long ago have been partitioned between the nations of Europe, very much like Africa. This would have brought endless dangers to the political and commercial development of the United States, nor would the Panama canal be an American enterprise today. The American manufacturer who is now beginning to enter these most valuable markets may still see his already very difficult undertaking fail completely, because, though his government has insisted upon political integrity of the Latin Americans, she has allowed complete foreign commercial supremacy there. The great trouble is that the South American knows as little about the North American and the United States as a country, about our customs, language, trade, commerce, and politics, as the average American knows about South America. As a consequence, the South American regards the Monroe Doctrine merely as an American 'bluff,' a menace and a political *bete noire*. He cannot bear the mention of it and imagines the United States uses this doctrine merely as a shield and pretext for the purpose of ultimately securing political supremacy from the Rio Grande to Cape Horn.

Unfortunately, and this is the crux of the whole difficulty, the very behavior and utterances of most North Americans in South American countries encourage this view. So firmly is this idea rooted in the South American's mind, that the giving of independence to Cuba, and Mr. Taft's strict adherence to the neutrality laws, almost to a point of censure, have availed absolutely nothing to change it. I regret to state that North Americans are most disliked in Latin America where they are present in great numbers, and herein nothing is at fault but his own personal behavior and disregard for the feelings and sentiments of the people among whom he is living and doing business. In traveling through Latin America I found that I was welcome everywhere and treated with the greatest cordiality and frankness so long as I traveled as a German, but when compelled to go as an American I found many a door closed and was treated with a reserved civility.

Pan-American conferences are being held, and diplomatic

visits are being exchanged, but even the tour of Mr. Root through South America a few years ago, and the visit of Mr. Knox to Central America did not tend to change South American views and in some instances did more harm than good. The true sentiment of political and commercial delegates is never expressed in the carefully worded speeches delivered over the cup of sparkling wine. American envoys and delegates would not feel flattered could they have heard many frank confessions that were made to me, as a German, regarding them, the 'Yankees' and their ways, and for reasons already pointed out, the Latin American has a great aversion to anything that savors of Washington, D. C., or that has any connection therewith. Possibly Latin America might have developed faster if left to the mercy of European aggrandizement, though this is open to argument, but one thing is certain and that is, if the United States had not upheld this doctrine the American flag would not fly over 48 states. It cannot be denied that this doctrine is also an irritant to other nations, who, despite the fact that the United States cannot possibly do police duty in every place, are fond of holding the United States responsible for everything that goes contrary to their own interests anywhere south of us. Only recently England tried to hold the United States responsible for the atrocities committed in the Putamayo rubber district because she did not do police duty along the Amazon basin, and only a few days ago a member of Parliament stated in an interview that, if it were not for the Monroe Doctrine, England 'might do something,' whereas, as a matter of fact, these atrocities can be charged directly to the greed and incompetence of the English directors of the great rubber companies, who now under the cloak of humanity, while purposely and greatly exaggerating these scandals, blame the Monroe Doctrine for not being able to 'do something.' When these scandals began to leak out, thanks to the successful wireless establishments (belonging to the German *Telefunken Gesellschaft*) between the Amazon district and Lima, the English commissioners hastened to explain that 30,000 Putamayo Indians had been murdered or lost their lives. As a matter of fact, the whole Putamayo district has never contained more than 30,000 Indians, most of whom are still alive.

It is often said that the caliber and capacity of a man can be gauged by the number and character of his enemies—the same can be said of the Monroe Doctrine. John Barrett, the director-general of the Pan-American Union in Washington, has recently voiced the true sentiment when he said that we must stop shouting about the Monroe Doctrine and make every effort to replace the same by the spirit and doctrine of Pan-American trade. Nothing is truer and more correct. How is this to be brought about? I might suggest an easy solution, but a discussion of such a commercial problem would fall entirely outside the scope of this paper.

In my opinion the Germans and French will always be the leaders in Latin America in the handling of certain goods and commodities and England will always be the leader in the field of transportation, but it will be left to the American to do the really big things there—it will be the American engineer and American banker who will accomplish the greatest achievements and win the greatest prizes. Goethal's work in Panama and E. L. Corthell's great work in Brazil are good illustrations of what may be done. There is absolutely no reason why the United States should not secure the entire trade in engines and heavy machinery, belting, and agricultural implements through Latin America. The great benefits of the Monroe Doctrine to the American nation are only beginning to be felt and will in due course be appreciated alike by North and South America. The Panama canal will do much to replace the political with the commercial doctrine of trade.

The disturbances in Mexico have indeed been exasperating and the United States has been lenient to her neighbor, but it must be understood that Mexico is undergoing more a constructive than a destructive period and that she is only now obtaining the experience that Argentina, Brazil, Chile, and Peru went through years ago, countries which stand today on firm political and commercial foundations. Mexico

is destined to become a great country, as great as Brazil and Argentina. After she has fought out her own battles she will settle down to greater peace and prosperity than she ever had before. I am quite sure that when the smoke of battle has cleared she will not forget her friend in need, the United States, and will make full restitution to those who suffered on her account. We must not forget that not so very long ago a much more bloody, much longer, and much more destructive war was fought at home, that millions of dollars of foreign investments were wiped out, property was ruined, pledges were disregarded, and that this country would have tolerated no outside interference. The very fact that the United States has not interfered in Mexico will in due course of time be appreciated more than anything we could have done, and the gain this will bring to the nation at large in prestige, in trade, and in commerce all over Latin America will be infinitely greater than all individual losses sustained.

The United States has absolutely no cause to change her policy regarding Latin America, but the individual American has much to learn with regard to these immensely rich countries and their peoples. If he would indeed 'get off the fence' he would find the Western hemisphere a safer place to live and in which to transact business. I do not believe he need worry much, as whether or not foreign nations like the American policy in Latin America, the important fact is that they are keeping their hands off. The Monroe Doctrine never was a police doctrine. Framed more in the spirit of self-protection, it has stood the test and has answered its purpose. It is now up to the Americans of this generation to reap the benefits and to establish the doctrine of Pan-American trade. The engineer, the exporter, the importer, the rancher, the farmer, the banker, the capitalist, the promoter, will each find a field for his labor in South America that is today unexcelled anywhere in the world, and each would do well to carefully study those countries. Do not hesitate to go there, but when you do go, leave your shouting American eagles to roost at home, watch the Germans, French, and English, and remember that in many things the peoples of South America can teach you more than you can teach them. If this be done, there will be less cause for misunderstanding, friction, and hard feeling.

JUAN FELIX BRANDES.

San Diego, California, November 25.

## Copper Producers' Association Report

The Copper Producers' Association statement, December 9, shows an increase during the preceding month in accumulation in this country of 9,419,095 lb. The details are as follows:

Pounds.

Stocks of marketable copper of all kinds on hand at all points in the United States, Nov. 1, 1912	76,744,967
Production of marketable copper in the United States from all domestic and foreign sources during November	134,695,440
Deliveries for consumption, November	69,369,795
Deliveries for export, November	55,906,550
Stock of marketable copper of all kinds on hand at all points in the United States, December 1.	86,164,062

The changes in surplus since December 1, 1911, have been as follows, in pounds.

	Increase.	Decrease.
December 1911	22,330,493	
January 1912	22,173,252	
February	3,301,944	
March	572,431	
April	2,927,829	
May	15,450,386	
June	5,280,639	
July	5,945,416	
August	3,579,046	
September	16,364,213	
October	13,679,380	
November	9,419,095	

## Special Correspondence

### MANILA, P. I.

DREDGING PROGRESS.—RESOURCEFUL PROSPECTORS.—COAL, IRON, AND OIL.

During the past year the Benguet district has been unable to recover from the setback which it suffered in the latter part of 1909. The Benguet Consolidated is no longer milling; the Major mines have shut down indefinitely; and the Headwaters mine has been having more or less trouble, though it still runs. Development work continues on the Kelleys. In Masbate the Colorado mine and mill is doing well under the superintendence of H. C. Wilmot, and is sending up a good sized gold bar regularly. Throughout the rest of the district there is nothing more than the usual assessment work and some development.

The most encouraging news comes from the Paracale district, which has had so many vicissitudes in the past. There are four dredges now at work. The Risdon is on the Malaguit river. The Paracale dredge is on the Paracale river. This dredge has been entirely overhauled and now belongs to the Paracale Bucket Dredging Proprietary Co. (controlled largely by Australian capital). Two new pontoons belonging to this company are in the water and part of the superstructure built. The Stanley dredge, which has been idle off and on due to litigation, has been working lately in the upper part of the Paracale basin. On the Gumaus river, in the same district, the Philippine Exploration Co. has begun operating its new dredge, built by the New York Engineering Co. This dredge has had only one clean-up and returned 275 oz. with the ladder on the bottom only three days. This has 5½ ft. close-connected buckets, passing 22 to the minute over the tumbler. Mr. Kane, the pioneer dredgemaster of the Philippines, is in charge of this dredge. Messrs. LeDue and Hanlon have been doing some placer work in the cocoanut grove in the neighborhood of Paracale. Their method is to sink a caisson through the saturated upper loose material and when the hard bottom ground is reached, drive a drift as in lode mining. In the early stages of the work, Mr. LeDue went down in a prospecting shaft which had filled with water, using an oil can for a diving helmet, into which air was pumped by the natives at the surface. Such is the resourcefulness of the American prospector, as well as the usefulness of the ubiquitous oil can. Mr. LeDue reports rich gravel.

Of quartz mining little can be said to be going on in this district. A new drainage adit to the San Mauricio mine from the mine to Mambulao bay is being driven, and it is hoped by those interested to be able to resume operations here shortly. At Cansuran, Surigao peninsula, Mindanao, the Surigao Gold Mining Co. has about 4000 acres of placer ground which it is sluicing. Some of this carries \$2.50 per yard, though the average would be doubtless much less. Many engineers have made estimates of the probable total yield of this ground and one of the most conservative engineers who has been in the field has made an estimate of \$4,500,000 upon the ground. The gold is usually about 790 fine. Mr. Parker, one of those interested, has several ½-pint bottles full of fair-sized nuggets in his house at Surigao.

In the coal basin it is regrettable to have to report the shutting down and sale at auction of the East Batan mine, on Batan island, which has been in operation since 1907. This is not the end of the coal business in the Islands, however, for there are other and better deposits which will be developed sooner or later. The experience of the East Batan mine will be of great benefit to future operators. When all the conditions are known, allowance will be made for the mistakes of this pioneer company. Philippine mines are not alone in their tribulations, as the Labuan (Borneo) coal mine has already caused five companies to fail. The quality of this coal and its principal characteristics were known long ago and pointed out in the bulletin issued in 1906 by the Philippine Mining Bureau.

There are no new developments to be recorded at this time in the Tayabas oilfield. The Government Bureau of Lands is making a topographic survey of a part of the peninsula. In the iron industry the only new development has been made by Charles Wilson, who has built a cupola 36 ft. high, 40 in. diameter, 12 ft. from charging door to tuyeres. In one week's run he turned out 2000 sets of plow points and shares which sold at 55c. each. This cupola marks a considerable advance over the crude native furnaces. Recently a heavy grayish mineral was brought in by a prospector from Antique, Panay island, which on

HEADWATERS 10-STAMP MILL.

examination proved to be wolframite. If this can be definitely established as having been found in the Philippines, it will be a great stimulus for mineral industries here.

### HOUGHTON, MICHIGAN

LOW WORKING COSTS IN COPPER MINES.—HIGH CRUSHING EFFICIENCY.

J. R. Finlay has stated that it is highly doubtful if the average cost of copper produced by the so-called Western porphyry mines will be as low as that of the deep mines of Michigan. In general the cost of producing copper in the Lake Superior district is being materially lessened. In 1908 the cost per ton of mining, transportation, stamping, and taxes at the Calumet & Hecla was \$2.15; in 1909 it was \$1.93; in 1910 it was \$1.92; in 1911 it was \$1.84. That is, a reduction of \$0.31 per ton was obtained in three years. The Calumet & Hecla ore, including amygdaloid and conglomerate, averaged 31.22 lb. of refined copper per ton of ore stamped in 1908; 28.18 lb. in 1909; 25.77 lb. in 1910; 25.47 lb. in 1911. The U. S. Geological Survey reports that for the total Michigan production in 1908, the average output of refined copper per ton of ore stamped was 21.2 lb.; 20.5 lb. in 1909; 25.5 lb. in 1910; and 20.0 lb. in 1911, or 1 per cent.

A few years ago certain seers in the Lake Superior district began to have visions of 'dollar rock.' But on account of the depth of the mines and the excellence of the mining practice then in vogue, these prophets were ridiculed. In view of the costs submitted for 1911, the prophecies do not now seem so absurd. The Osceola company in 1911 was mining, transporting, and stamping ore, and paying taxes, at a cost of \$1.14 per ton; Ahmeek is doing it at \$1.42; Mohawk at \$1.406; Isle Royal at \$1.42. The last mine has reduced the cost from \$2.33 in 1908 to \$1.42 in 1911, a difference of \$0.91 in three years.

The reductions in cost are due to increased efficiency underground, where lighter rock-drills have supplanted the old 'slugger' types, and to improvements in mill practice. The stamp-mills have introduced steeple compound heads, regrinding apparatus, and pebble-mills. It is interesting to note in passing that there are less than 100 stamps in the entire Michigan district. In 1910 there were milled 10,869,561 tons, and a number of stamps were idle. Ordinarily the Lake Superior steam stamp has a capacity of 320 to 700 tons per day, according to type of stamp, size of screen, and kind of ore. Several stamps have been improved to such a degree that they crush 800 tons per day.

Most of the mines do not report the cost of milling the

ore. It probably averages in most cases over 20c. per ton of ore stamped. The Osceola company reported a cost of 17.47c. for 1907, and 15.78c. for 1908. During 1911 there were eight mines which paid dividends; the same was true in 1907. In 1908, 1909, and 1910, there were seven mines which paid dividends. There are usually between thirty and forty copper mines operating or exploring, the stock of practically all of them is traded in on the stock market. The eight mines which paid dividends in 1911 are controlled by four different mining companies.

### MELBOURNE, AUSTRALIA

FLUXING ORE FROM PAPUA.—A QUARTER CENTURY'S PROSPECTING.—NEW SOUTH WALES MINING MEASURES.

The Great Fitzroy Mines, Ltd., in Queensland, a Bewick, Moreing & Co. flotation, has acquired an option over the Laloki mine on the Astrolabe field, in Papua (British New Guinea). The mine is only 17 miles from Port Moresby, with which, it is understood, the Government intends to connect it by rail. The mine, which is held by a small syndicate, was worked by the British New Guinea Development Co. on option, and abandoned, owing to the high cost of transportation by road. The Great Fitzroy is taking it over in the belief that it will provide suitable fluxing ores. Down to a depth of about 20 ft. the ore is gossan; for the next 30 ft. there is a secondary enrichment with chalcocite, covellite, etc., containing about 20 or 25% copper, below which the copper content decreases to 3 or 4%. The content of the ore is given as 2.8 to 4% copper, 43.8 to 50% iron, 4.1 to 9.6% insoluble matter, about 45% sulphur, 2 to 3.1 dwt. gold, and 0.35 to 4.3 oz. silver per ton. For profitable working it will be necessary to handle between 500 and 600 tons of ore per week and G. C. Klug, the Bewick, Moreing & Co.'s representative, estimates that at least 200,000 tons will have to be proved by development before the company will be justified in equipping the mine. The development recommended will cost \$25,000 or \$30,000. For the option a sum of \$25,000 is being paid, and there is to be a royalty of 50c. per ton payable on all ore treated during the time of the option. The harbor at Fort Moresby is to be deepened to allow of the berthing of bigger ships than it can accommodate at present. If the enterprise proves successful it will be a great thing for the mineral industry of Papua.

Twenty-five years is a fair length of time for the driving of an adit to be carried on, but that is the period over which the Bright District Prospecting Co., a Victorian concern, has been driving to intersect at depth certain veins which have been worked above. Not until this month had any success been met with; but now, in a drift some 260 ft. from the main cross-cut, a highly mineralized auriferous vein has been found. Assay values, according to daily samples, are from 5 dwt. to 1 oz.; but daily samples can be made to prove anything, and it is necessary to wait for systematic sampling or, better still, for mill results, before pronouncing an opinion in regard to the value of the find. The vein where cut has a width of only 12 in., but there is 1560 ft. of backs, so it may be that the company has a good thing. Certainly such remarkable perseverance deserves some reward.

In the New South Wales Parliament, the Mines Inspection bill and the Miners' Accident Relief Fund Amendment bill have both been withdrawn, through the pressure at the close of a session when it becomes necessary to lighten the load of legislation. The wages award in the coke-making industry of New South Wales may give Americans some idea of the happy conditions of the Australian laboring classes. A week's work is to consist of 48 hours (in most industries it consists of not more than 44), and Sunday and holiday work is fixed at double rates. Preference of employment is given to members of the Coke Workers' Association. An employee must be allowed time off to attend delegate meetings which he is appointed to attend, provided his employer is given 24 hours' notice. These terms must not be supposed to be unusually favorable to the workers. They are, in fact, unusually moderate.

Whether, however, the excellent terms the workers can now demand will be maintained through periods of depression remains to be seen. At present, anyway, the working man is master of the situation. He is exacting his full pound of flesh and giving in return for it as little as he can.

### JOHANNESBURG, TRANSVAAL

SEPTEMBER OUTPUT.—HIGHER YIELDS AND COSTS.—THE FAR EAST RAND.

During the month of September the average recovery per ton milled on the Rand is given by the Chamber of Mines as 28s. 7d. as compared with 28s. 9d. for the month of August. Throughout the whole of the year since January there has been a steady improvement in the average yield, but in September a slight setback in recovery is to be noticed. It is difficult to trace the cause of this improved yield, but it may be due to the tendency which has been shown lately to send a higher grade of ore to the mill by restricting mining to the richest parts of the property, of which several instances might be quoted.

There is for instance, the East Rand Proprietary mines, where the grade of the ore sent to the mills has appreciably improved. Considering the large output from this property such a changed policy is calculated to make itself felt on the whole output. Several other large producers have been adopting a similar practice, so that there is every appearance that, coupled with the more satisfactory results obtained in the Far East Rand, the changed working policy may account for the higher grade of ore sent to the mill. Another factor in support of this view is the higher level attained by the working costs. While the grade has been going up, the working costs have also, until at one time it seemed doubtful whether there was any benefit to be derived by sending a better grade of ore to the mill. Such consequences are just what may be expected as a result of selective mining. Whether it pays to improve the grade to obtain such a small increase of profits at the expense of the working costs must all depend upon the surrounding circumstances.

Another month has passed without the results of the reduction in railway rates being made apparent in the Rand working costs. Last month the cost was 18s. 8d. per ton, just the same as in July, the month before the reduction in railway rates took effect. Undoubtedly considerable effort is apparently made to reduce the working costs on the Rand and operators are loth to believe that this steady increase in working costs is due to the growing depth from which the ore is being mined, regarding it as more likely due to the practice of selective mining in the attempt to increase the profits. Last month the profits averaged 10s. per ton milled; the total working profits made on the Rand being in September, £1,040,820.

Since the discovery in the Modder Deep, which exceeded all anticipations, more attention has been devoted to the Far East Rand, where several important shafts are being sunk. Perhaps the least important is the circular shaft of the New Modderfontein, which has just proved the reef, and accompanying partings, to be 48 in. wide, with an assay value of 13 dwt. per ton. To the New Modderfontein company, however, the find is of immense importance, as also to the Modderfontein Deep, as it proves that probably the well developed and satisfactory vein discovered in the Modderfontein Deep is no patch, but covers an extensive area. This would also appear to be the case by other discoveries in the neighborhood of the original one on the property.

It is to be regretted that better finds were not made in the two westerly shafts of the Government Areas, as the position of the shafts is such that more favorable results might perhaps have been expected. But the other two shafts going down to the east of the Brakpan mine are situated in interesting ground, and may possibly make up for the disappointment resulting from the only ordinary ore found in the western part of the property. Farther to the east the Springs mines are making good progress, with

the shafts in what has all the appearance of being a promising area. But seeing that so far its value has only been indicated by bore-holes, not much reliance can be placed upon the results until the reef has been intersected by a shaft and driven upon some distance. The Far East Rand is the only area where shaft-sinking is now carried on to any extent and it is not difficult to see that, providing the Rand continues to increase its output of gold, it will be from this area that most of the increased output will be obtained. There is not much scope for further extension on the central Rand, while on the western Rand the reefs are covered by great thicknesses of overlying dolomite, making prospecting an almost impossible task.

### NEW YORK

SOUTHERN PACIFIC DECISION.—NEW GRANBY PLANT.—A NEW DISTRICT.

Following the handing down by the Supreme Court of the United States of the decision in the Union Pacific-Southern Pacific merger suit, there has ensued a period of depressed bewilderment that has apparently involved all of Wall Street. That part of the Street which has not developed as acutely bearish is hesitating, much befogged, and is seeking for new points of the compass. Prices have suffered generally, and as yet there has been no evidence of a strengthening of the situation or a stiffening of prices. To point to any one particular cause as responsible for the present slump and unsettlement is impossible. It would be presumptuous to declare that the foreign situation has ceased to be an active market factor. It is generally believed by the Street that peace is to be restored in Europe, and that a general conflict will be averted. There remains, however, the bill to pay, and the nations realize as never before the cost of warfare, even when such operations are of no greater magnitude than those recently conducted in European Turkey.

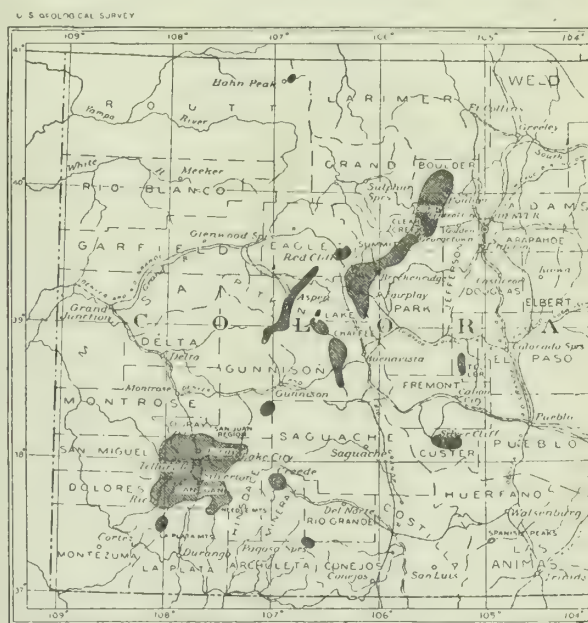

The economic issues that constitute the gravest problems confronting the country are taking shape in the developments from day to day, and, as important underlying factors, are not without market influence. As the Pacific Coast has wrestled with the Union Pacific-Southern Pacific combination, so New England is making heroic efforts to overcome the domination of the New York, New Haven & Hartford Railway Co. The Federal Grand Jury is now investigating the recent squelching of a competitor of the New York, New Haven & Hartford, and the possibility of criminal proceedings against some of the best known men in the financial world is not one to reassure market operators. The banking situation in New York, which very directly affects the whole country, is receiving its due share of attention, while the 'money trust' investigation is about to recommence, and an important statement has just been made by the Secretary of the Treasury. Undoubtedly the most important suggestion that is made, among others, is his insistence upon the great necessity "for independent banking units—so independent that no one bank can be owned, controlled, or shared in any degree directly or indirectly by any other bank."

In the face of the general success of such bear attacks as have been organized, Braden Copper has made a most striking advance. The shares registered a high mark of \$10.62 at a moment when listed shares on the New York Stock Exchange were in precipitate retreat. Just how successful a campaign of distribution is being made in Braden is hard to estimate. From the reports given to the press it is evident that the property is expected to develop into one of the most important copper producers of the world, with a tremendous ore reserve and a very low copper cost. J. P. Graves, general manager for the Granby Consolidated Mining, Smelting & Power Co., is about to call for bids for the construction of the new 2000-ton smelter for the Hidden Creek property.

The passing of the quarterly dividend by the Goldfield Consolidated subjected the Nevada precious-metal stocks to considerable pressure. The Tonopah issues were sold freely, and this part of the market very noticeably felt the effects

of the prevailing gloomy atmosphere, an atmosphere by no means dispelled by the various dividend declarations. The distribution of an extra payment of 50c. per share by the Nevada Consolidated was largely without effect, owing to the majority of the issued stock being held in the treasury of the Utah Copper Co. It is worthy of note that the Nevada Copper Co. declares this extra 50c. from accumulated surplus, and the distribution is therefore to be considered as a part return of principal invested rather than a distribution of earnings. The shareholders are counting upon an increase in the quarterly distribution of the Utah Copper Co. for the first quarter in 1913 as a result of the increased receipts from Nevada Consolidated. The possibilities of a big consolidation or merger in Ely, Nevada, were not received as a good omen market-wise by the holders of Giroux, this issue having been one of the weak spots in the mining-share list for the past several days. There is hardly a copper property in which the public is interested, with the standing exception of Trinity Copper, which is as much of a mystery as Giroux.

Followers of mining markets throughout the East are hoping that new interest in the mining-share list will come through the discovery of new areas, an encouraging report

COLORADO.

having been received from Colorado to the effect that a new district has been discovered in that state near Monte Vista in Conejos county. The thorough exploration of the mineral-bearing possibilities of the world has been mentioned heretofore in this correspondence. Along this line it is interesting to note that the present Government of Panama is just passing a bill for the policing of the San Blas country, a part of the territory of Panama which is believed to be rich in minerals, but which has never been thoroughly explored on account of the inability of the Government to protect prospectors against Indians.

As a part of the Eastern campaign being made to distribute the stock of the El Paso Consolidated Gold Mining Co. of Cripple Creek, the company has had placed on exhibition a large glass model of the El Paso mine showing the various levels and shafts, and also showing the Roosevelt drainage adit, upon which the recent movement in El Paso is based. In the state capitol at Albany there has been for many years a complete model of the old Valenciana mine at Guanajuato, Mexico, a property which is credited in history with being the greatest precious-metal producer of the world, but which has been filled with water for many years.

The Ahmeek Copper Co. still retains its premiership as a dividend payer among the newer copper companies of the Lake country. Its recent declaration of \$7 is for the

quarter just closed. The last quarterly dividend was \$6 per share. Six months ago \$5 was paid, nine months ago \$4, and one year ago \$3. The coming back of various leading copper companies into the dividend ranks is very gratifying, but at the same time it is a little discouraging to note that Nevada Consolidated has sold down to \$19 just after the declaration of its extra payment.

Copper circles have anticipated a somewhat unfavorable statement. Estimates of the decrease range from 15,000,000 to 30,000,000 lb. [The increase was actually 9,420,000 lb.] The situation is due to restricted exports partly because foreign consumers have drawn more freely than usual upon reserves abroad (the last fortnightly figures showed a decrease of 6,000,000 lb. in visible supply) and partly due to a lack of bottoms for loading. The Hamburg-American Line has leased quite a number of new vessels that will be used principally to handle export copper, but this betterment will not be noticeable until the February report appears. The copper metal market is a rather dull affair. Foreign trade has not been in evidence during the week, and the majority of the business has been that of supplying smaller domestic consumers. As in most other lines, manufacturers consuming copper are disposed to proceed with great caution.

### AUSTIN, TEXAS

HAZEL DRY CONCENTRATOR. — SHAFTER OUTPUT. — THE QUICKSILVER INDUSTRY.

The new dry concentrator of the Hazel Mining Co., about 15 miles northwest of Van Horn, was recently started to treat the old dumps, which contain about 100,000 tons of ore, said to average \$15 in copper and silver per ton. This mine has a good producing record, but has been inactive for several years. The new plant has a capacity of 100 tons per day. Charles Culter, of Dallas, and associates, comprise the company that now owns the property. During a period of about ten years that this mine was worked by A. C. Schriver, of San Antonio, and associates it is said to have produced ore to the value of about \$500,000. The ore averaged about 10% copper and 50 oz. silver per ton, and one carload shipment was made that netted \$5000 per ton.

Preparations are being made to open up several old prospects in the territory around Van Horn and Sierra Blanca. Some of these old claims are known to be very promising in copper and silver ore as well as some gold. The Maltlay mine in the Van Horn district, which was worked by Jacob Hahn about 25 years ago and produced considerable quantities of copper and silver ore that averaged about \$40 per ton, is being investigated with a view to operations being resumed. In the Shafter district of Presidio county the old Shafter silver mine is keeping up its splendid record of production. The present year will show an increase over the output of any previous year, it is said. Considerable prospecting is being done in that district and arrangements are being made to develop several new claims.

Reports from the Terlingua quicksilver district, 90 miles south of Alpine, are not altogether encouraging. It is stated that there is a falling off in production of cinnabar ore and that the opening up of new properties which was proposed a few months ago, has been postponed. The plans for the construction of a railroad into the Terlingua district have also been abandoned, it is now reported. The receivership of the Kansas City, Mexico & Orient railroad which is now being constructed into Alpine from the north, will greatly delay if not entirely cancel the plans for building the branch line of that road to Terlingua. While a railroad is not essential to the operation of the quicksilver mines except that it enables the bringing in of supplies at a low cost the remoteness of the Terlingua district at present places it out of touch with investors and prospectors, and in this way the development of the well known riches of that section is seriously hampered. If the road should be constructed, local men confidently expect steady growth of the mineral industry to follow.

### TORONTO, CANADA

THE PORCUPINE STRIKE. — ARRESTING STRIKERS. — NICKEL AND THE WAR.

The Porcupine strike shows no signs of coming to an end and has resulted in numerous disturbances, one of them of a decidedly serious character. The leading mines have been bringing in strike-breakers, but most of these have yielded to the more or less forcible persuasions of the strikers and their sympathizers, and have refused to go to work. However, the forces of the Dome and Hollinger are being hourly augmented and operations at both mines are going on steadily. On December 2 the detectives employed by the mine owners fired into a crowd of strikers congregated in front of the hotel at Timmins with a view to conferring with a recently arrived party of strike-breakers. A number of shots were fired and four of the strikers wounded. There are, of course, the usual conflicting statements as to who is to blame, and whether there was any necessity for the shooting. Several of the detectives were arrested, and one of them, Ferdinand D. Luke, who was identified as having fired on the crowd, was committed for trial. The local magistrate has been kept busy hearing charges of assault, intimidation, etc., preferred by both sides, and numerous heavy fines have been inflicted, with apparent impartiality.

One result of the shooting affray has been to place the duty of preserving the peace in the hands of a large detachment of Provincial Police, as the local feeling against the detectives and special constables is bitter and likely at any time to result in bloodshed. This week the Hollinger company is trying a new tack, and has sworn out warrants against some 300 of its former employees for a breach of the Lemieux act in going out on strike without first giving notice. Under the provisions of the law this renders them liable to a fine of \$10 per day. It is the first time that a case of the kind has been brought, and it will be made a test case, as most of the other mines affected could take similar action. The strike has affected the stock market adversely and there has been little demand lately for Porcupine issues.

Cobalt stocks have attracted more attention, among the most active being Cobalt Lake, which has at last reached the dividend-paying stage, having declared its initial distribution of 2½%. The output for the mine for the current year is estimated at approximately 1,000,000 oz. of silver and the net profits will be about \$450,000. Early next year 20 more stamps will be added to the mill, at a cost of about \$50,000. The statement of La Rose for October showed a net profit of \$97,002. During the first ten months of 1912, 2,272,584 oz. of silver was produced, and net profits of \$777,296 realized. The surplus on hand, including outstanding shipments, etc., was \$1,658,881. The company has renewed for five years its contract with the Northern Customs concentrator for the treatment of its low-grade ore, calling for a delivery of 100 tons per day. The Preston-East Dome, which, since the closing down of its Porcupine holdings, has been operating the Silver Bar of Cobalt as a forlorn hope, has uncovered a 6-in. vein of good ore on the 50-ft. level. The Buffalo, in addition to its regular 5% dividend, has declared an 18% bonus payable January 1, and an additional 3% bonus to be paid in February.

The European war situation and the increased demand for battleships has greatly stimulated the Sudbury nickel industry. Existing companies are extending their operations and new enterprises are being organized. The Canadian Copper Co. has acquired part of the northern range from the Lake Superior Power Co., and is opening up the Fronde mine and other workings which have for some time been closed. The Mond Nickel Co., which has been operating on a small scale and shipping its output to England, is putting up a large smelter for the production of nickel matte. The Dominion Nickel Co., which owns the Whistle and the Murray properties, but was deterred by former market conditions from entering into competition with the companies already in the field, will build a new smelter and operate on a large scale.

## General Mining News

### ALASKA

#### FAIRBANKS

There are now 16 mills in the Fairbanks recording precinct, 12 of which are built or are being built at the mines themselves, and all will be at work in December. In nearly every case the mine-owner has taken out enough ore from the property to pay for the mill. The mills are situated as follows: One on Ester, that of the Hudson brothers; two on Dome creek, owned by Mr. Spalding; two on Cleary proper at the Newsboy and the Newsboy Extension; one on Willow creek at the Tolovana claims; one on Bedrock creek at the Rhoads-Hall vein; one on Twin creek at the Rainbow; one on Wolf creek at the Rexall; two on Chatham creek at the North Star and the Chatham Creek Mining Co., and one on Fairbanks creek for the McCarty and Fursteneau claim.

#### SEWARD

S. Silverman is authority for the statement that the gold produced in the interior and taken through Seward during the past season, has been nearly \$200,000, coming from about six different properties. W. Martin has recovered \$45,000 from 60 days' work near Knik; the Gold Bullion, in 80 days, produced gold worth \$74,000, and concentrate valued at \$20,000; M. Kelly took out \$35,000 from claims on Willow creek in 60 days; Hayden cleaned up \$15,000 in 21 days on Falls creek; the Primrose produced \$8000 during the season, and has good prospects; in 30 days \$400 was won with a 2-stamp mill at the Skeen Litchner claims, and \$45,000 has been spent on development; and over \$40,000 passed through Seward from the Cache creek country.

### ARIZONA

#### COCHISE COUNTY

The Calumet & Arizona smelter in November yielded 4,918,000 lb. of copper, compared with 4,404,000 in October. The Copper Queen mine produced 7,951,746 lb. of copper, while the total output of the Phelps-Dodge mines was 12,888,937 pounds.

The State Supreme Court has handed down a decision in the case of Bowman v. Warnekros, which involves the payment of 10% commission on the sale of certain claims to the Great Western Mining Co., of Courtland. Bowman claimed 10% from Warnekros for completing the sale, but the latter denies that the former made a sale, although Warnekros admitted he authorized Bowman to make the sale; but the latter was not in authority when it was actually completed. The District Court held for Bowman, and Warnekros appealed. The last decision remands the case to the Superior Court at Tombstone with instructions to grant the Warnekros demurrer.

In the Federal court, hearing of the appeal of the bondholders of the Tombstone Consolidated Mines Co., bankrupt, will be heard on December 23. When this is settled, some definite policy will be announced regarding these properties.

#### GILA COUNTY

(Special Correspondence.)—The Cole Development Co.'s present activity is one of the most potent indices of the recurrence of mining activity of the western portion of the Globe-Miami mining district. The Cole Development Co. was organized under the laws of Arizona in 1909 with a capital stock of 300,000 shares, par value \$1 per share, the amount of stock issued being 112,000 shares, and the amount left in the treasury 188,000. The company will now sell 12,000 shares of stock for 40c. per share, and the money received from the sale of this stock will be used to further equip this already well equipped property. Under the new arrangement, development work will be continued at an accelerated rate, and the ore already developed will be extracted as rapidly as possible. Ore shipments will be begun at once. The property is marked on the

U. S. Geological Survey maps as the Cole & Goodwin mine and is too well known to need any elaborate description. The group includes 17 claims on the faulted zone where the ore occurs, and has a length of 6000 ft. along the fault. The present improvements consist of a 400-ft. inclined shaft, 22-hp. gasoline hoist, heavy head-frame, skips, cars, and tools. From the creek level, below the shaft, a 480-ft. cross-cut adit is now within 50 ft. of the fault. The property lies about three miles east of Gibson, or 15 miles west of Miami, and has a good wagon-road to the latter copper centre.

At the Miami plant extensive improvements are in progress in the way of erection of buildings and installation of equipment and the usual progress in development is being maintained. The new mine machine-shops are completed, and the engineering force has entered the new and well equipped offices. The same building contains the mine offices. The concrete foundation for the miners' change-room near No. 4 shaft has also been finished, and the new hospital building is well on in course of construction. Two churn-drills are being operated on the property, and two diamond-drills are being used in the sinking of a perpendicular hole from the lowest level of the mine. Another 600-hp. boiler, the fourth, has been installed at the power-plant, and is now generating power. Production for October reached 2,789,000 lb. of copper, the amount of ore mined being 95,439 tons.

At the Old Dominion, at Globe, there are no new underground developments to record. On the surface, the new crusher-plant excavation work is progressing well, and should be complete by the middle of December. A new 750-kw. turbine has been recently installed at the smelter power-plant, and a new geared hoist will be shipped from the factory early in December for erection at 'A' shaft. The management hopes to have its new basic converters running in January 1913.

Mr. Henderson, the general manager, expects to take out six carloads of about 16% copper ore from the Summit this month, as against seven carloads in November. The lessees also will ship two carloads as they did last month. There are two parties of lessees extracting ore at the Gibson, one party on the Pasquale vein, and the other on the Summit vein. The ore now being taken from the property by the company is on No. 4 level, but as soon as a chute has been finished to the No. 6 level, the ore from the No. 4 level will be dropped through to the No. 6, and the intervening ground between those two levels will be worked from the No. 4 to the bottom.

The ore recently discovered in the Superior & Boston continues as the driving and other exploration work along the vein progresses. The east drift of the No. 8 level continues in this ore and the raise started from the point on that level where the ore first was found has been driven 20 ft. toward the No. 6 level, and is all in ore. As there is nearly 4000 ft. of unexplored ground in the eastward direction in which the No. 8 level drift is following the ore, the prospects for development of ore of good grade seem unusually good.

Globe, December 5.

The Ray Consolidated Copper Co. has completed arrangements to work the Ray Central property, and production will start during December. It is stated that the Magma Copper Co. will obtain control of the Queen company's leases early in 1913. The Calumet & Arizona company has put on more men to work on the roads. The Douglas Copper Co. will develop its property next year by churn-drilling. Eastern capital is interested, and engineers have been examining it during the past six weeks.

#### GRAHAM COUNTY

In November the Shannon Copper Co. produced 1,436,000 lb. of copper, against 1,210,000 lb. in October.

#### PIMA COUNTY

The Oceanic mine in the Arivaca district has been bonded for \$60,000 to C. T. Tryon and associates, who are well known at Tucson. The ore is free milling, and the mine has produced a fair amount of gold.

## SANTA CRUZ COUNTY

The Copper Queen company has discontinued work at the World's Fair mine, in the Patagonia district, which would have involved a deal of \$800,000. Work on other options in this district is being continued by the company.

## CALIFORNIA

## CALAVERAS COUNTY

(Special Correspondence.)—The 10-stamp mill at the South Carolina, near Carson Hill, is about to go into commission. Development at the mine is advancing steadily, and considerable ore is ready for treatment. The mine was recently acquired by Joseph A. Peirage & Co. The Finnegan Extension is keeping the 10-stamp mill at work. Ore lately uncovered is stated to be of good grade. The Hardy-McCreight mine, on Chaparral Hill, is rapidly being prepared for production. The old workings have been cleaned up and repaired and considerable ore opened. The owners are planning the erection of a 5-stamp mill. The property is situated three miles south of Angels Camp. James G. Maltman is superintendent. An 8-ft. vein of \$14 ore is reported from Fazzi mine, north of Altaville. The strike was made at a depth of 50 ft., and the ore is said to carry rich pyrite in addition to the free gold content. The vein is supposed to be the continuation of the Sultana-Keystone lode. Andrew Fazzi is managing owner. The Angels branch of the Calaveras Chamber of Commerce is preparing to collect a high-class exhibit of Calaveras minerals for display at the Panama-Pacific Exposition. Lack of water continues to handicap mining operations in this district. The dry season has been exceptionally prolonged. The Calaveras Copper Co. is maintaining a fair extraction from its Copperopolis mines, and shipping to the Mammoth smelter at Kennett. The company will make a heavy production early in the coming year. Boston and New York people are largely interested.

Angels Camp, November 30.

A fire, believed to be the work of an incendiary, destroyed property valued at \$75,000 at the Reiner gravel mine, situated a half-mile north of Altaville, on December 7. The damage is partly covered by insurance.

## INYO COUNTY

The Saline Valley Salt Co. continues to work steadily. All the towers are finished from Saline across the summit, and work is under way at the Saline loading terminal. Methods of collecting the salt have been improved, and a double track railroad will run from the terminal out on the field. Cars will be moved by cable traction and stationary engine. By next spring, it is expected that the buckets will be dumping salt at the Swansea terminal.

## KERN COUNTY

The production of oil during November was over 8,000,000 bbl., and the total for 1912 is estimated to be nearly 90,000,000 barrels.

## MARIPOSA COUNTY

A two-drill air-compressor has been installed at the Whim shaft lease, near the Mariposa mine, and development will proceed faster. This shaft is down 200 ft., and a vein 24 in. wide has been opened at the bottom.

## MODOC COUNTY

(Special Correspondence.)—The Sunshine company has on view in San Francisco, a large sample of ore which is part of a shipment of 6¾ tons sent to smelters, and averaged 8.38 oz. of gold, and 16.76 oz. of silver per ton; the net return being \$159.24 per ton, and total of \$1020. An adit is in 300 ft., and three shoots of ore are being worked on the property. At 175 ft. in, a drift has been driven 40 ft. north on a vein. Two shafts are down 42 and 27 ft., with 6 to 12 in. of hard ore. The installation of a hoist and compressor is contemplated. At the Modoc mine, the shaft is down 150 ft. Two shifts are being worked. From a lease of the Sunshine company, five tons of ore sent to the Big Four mill yielded \$11 from the plates, and the average value was \$21.40 per ton. The Lucky Dutchman lease shaft is down 40 ft. The Sunset-Hummer

claims, owned by Williams & Wall, situated at the south end of the High Grade district, shows 3 to 5 ft. of ore worth over \$20 per ton.

San Francisco, December 6.

## NEVADA COUNTY

The new 14-stamp circular Straub mill at the Birchville mine, near Graniteville is in operation. It is of new design, and will crush 30 tons of quartz ore in 24 hours. Water-power is used for driving the machinery; also for generating electricity for compressors and lighting. A fine orebody was uncovered at the Birchville some time ago, and profitable returns are expected.

Work has been started on the new cyanide plant at the Champion mine, on Deer creek; and when it is ready, the North Star company will be able to treat the Champion tailing in this plant. Development in the Champion property is encouraging.

## PLUMAS COUNTY

Reports from the Seneca district state that the California-Nevada Mining Co. is installing a 30-ton mill of the arrastre type, one of the improved mills popular as a prospect mill. Development next summer will depend on

mill tests from Pezzoni's claim, in the vicinity of Old Diggings, at Butt Valley.

## SHASTA COUNTY

(Special Correspondence.)—It is rumored that the Bully Hill Copper Co. may commercially test its new process for treating copper ore in the near future. It is understood that negotiations are pending with the Federal Government for permission to blow in the furnaces. The mines and plant are situated near Delamar. Representatives of the Oro Water, Light & Power Co. are vigorously prospecting the placer deposits along Clear creek. The Peterson ranch is being given particular attention, and options are said to have been taken on the Saeltzer, Jones, Mullen, and other tracts. The Clear Creek dredge is operating on adjacent territory, and is understood to be earning good profits. A new furnace is being completed at Heroult by the Noble Electric Steel Co. The last run of the old plant is understood to have satisfactorily demonstrated the practical application of the improved method of electric pig-iron smelting. A new process for the elimination of fume in smelting ores is being tested, and the inventors claim results are highly encouraging.

Redding, December 2.

Two 350-hp. motors formerly used in the Cottrell

plant, at the Balaklala Copper Co.'s smelter at Coram, are being sent to Tacoma. The \$30,000 brick stack is crumbling away, and will damage the Cottrell plant if it falls.

The bag-house equipment of the Mammoth smelter at Kennett suffered damage on December 3, through the concrete foundations supporting the fans in the steel flue, leading from the flue-chambers to the cooling-pipes, collapsing. The fans are used in the fan house, midway between the flue chambers of the furnaces and the cooling pipes to reduce the temperature of the fume before being admitted to the bags. They are 16 ft. diam., and are driven by two 250-hp. motors. Repairs are being made with all speed, but it may take a week or more to complete the work.

#### SIERRA COUNTY

(Special Correspondence.)—Among recent finds of real importance is that of high-grade ore in the Chispas mine of the Swastika M. Co. This concern has been working for two years opening the mine, and while details are not available, it seems clear that a discovery of real value has been made. The Tightner, too, is now working in excellent ore and the good judgment of A. D. Foote and his associates of the North Star company, in taking hold of this property, seems to have been amply confirmed. Another of the old properties being reopened is the Gold Cañon, which is being handled on bond and lease by C. C. Derby and associates. The mine, which has a recorded production of \$750,000, had been idle several years when Mr. Derby took charge. Water under 1200-ft. head is available and pipe-lines and a power-plant have been put in preparatory to the active underground work that is now beginning. The shaft is down 400 ft., but only a small area in the plane of the vein has been mined.

Nevada City, December 6.

There are 50 men taking out gravel at the Bellevue mine, in the north part of this county. The gravel averaged \$90 per carload. Work is being done by an incline, 15 ft. vertical depth. F. and W. Bosch have their property in order for winter work, and will work underground as long as there is no water to sluice with.

A rock-crusher weighing 12,000 lb. has arrived at the Sierra Buttes mine, at Sierra City. It was hauled on a wagon from the Western Pacific railroad at Beckwith.

#### COLORADO

##### HUERFANO COUNTY

The Colorado Fuel & Iron Co., Denver, is installing additional apparatus for equipping its mine at Picton, Colorado, with electric drive. The installation includes a 500-kw. rotary converter, two motors of 235 hp. each, four motors of 200, 150, 100, and 65 hp., respectively, and switchboard apparatus. For operating its Coal Creek mine at Canon City, Colorado, new electrical hoist apparatus consisting of a 125-hp. motor-generator set, 250-hp. motor, air-compressor, and switchboard is being added to the power-house equipment. All the apparatus is of the General Electric Co. manufacture.

##### LAKE COUNTY (LEADVILLE)

The output of the district for November was slightly below that of preceding months on account of car shortage, which is improving. The Ibex property retains its position as a heavy producer, and several lots of ore were settled at the Arkansas Valley plant at 70 oz. of gold per ton. Besides the iron ore from Fryer hill, a fair tonnage of carbonate of zinc is being shipped. The Cosmopolitan adit is in about 900 ft., in the direction of Corinne mountain. In the face there is a mineralized formation with a strong flow of water through soft porphyry, and the acid water is causing bad air. In the spring it is intended to overhaul the adit and drive it about 500 ft. farther. Several cars of good sulphide ore has been shipped from the old R. A. M. dump.

##### TELLER COUNTY (CRIPPLE CREEK)

According to local figures, November was a banner month for dividends in this district, no less than \$106,500 being

distributed in dividends, while large amounts also went to the stockholders in the several close corporations that are operating profitably in the district. The dividends announced were: Elkton, \$50,000; Golden Cycle, \$30,000; Granite, \$16,500; Gold King, \$10,000.

The output for the month amounted to 76,697 tons, of a gross value of \$1,167,235, and an average value of \$15.21 for all ore treated. This is an increase in tonnage and a slight decrease in total value as compared with October, the change being due to the increased activity of the various local mills in handling the lowest grades of mine and dump ore. The figures as reported from the various plants follow:

	Tons.	Av. Val.	Gross Val.
Smelters .....	3,855	\$65.00	\$ 250,575
Golden Cycle .....	30,000	20.00	600,000
Portland (Colorado City) ..	9,570	22.00	210,540
Portland (Victor) .....	15,350	3.15	48,352
Stratton's Independence ...	11,222	3.12	35,013
Gaylord (Dante) .....	1,800	3.00	5,400
Kavanaugh .....	1,500	2.15	3,255
Wild Horse .....	900	4.00	3,600
Blue Flag .....	1,500	6.00	9,000
Isabella (tailing) .....	1,000	1.50	1,500
Totals .....	76,697	\$15.21	\$1,167,235

Production from El Paso mine during November was 144 cars of ore, of which the company sent out 100 cars averaging \$30 per ton, and lessees 44 cars of \$18 per ton. The former ore was mined from No. 5, 6, and 10 levels. The Isabella shipped 101 cars, of which 29 lessees owned 97 cars. The company mined four carloads from the new orebody on the 1275-ft. level. Twelve machines are working from a compressor at Lee shaft, and lessees in the Empire State are buying air from the Western Investment Co. for four machines. The Colburn mill is treating 78 tons per day. The 4-in. pipe from a spring at Union Park to El Paso mine, two miles long and costing \$5000, has been completed, and is now supplying good water for the mine. Shortage of water has been a drawback to living on Beacon hill. Twelve sets of lessees are working at the Gold Dollar mine. The quarterly report states that revenue from ore shipped and royalties totaled \$15,988, while cash on hand amounted to \$18,573. During November the Vindicator company shipped 60, and lessees 40 cars of ore, worth \$35 and \$25 per ton, respectively. The Elkton company sent out 2500 tons of ore in November. About 1300 ft. of driving has been done on No. 11 level. Between 5 and 6 ft. per day has been sunk in hard granite at the Maid of Orleans mine, working two shifts. The shaft is nearly 900 ft. deep.

On December 1 the flow of water from the Roosevelt tunnel was 8650 gal. per minute. So far, the electric pumps at the Golden Cycle shaft have not been entirely satisfactory. A severe storm has been raging over Colorado, accompanied by cold winds and much snow. At Cripple Creek the blizzard was particularly strong, and the wires of the street lighting system were blown down. Power wires have kept up all right.

#### IDAHO

##### LATAH COUNTY

There will be a winter short course of instruction for miners and prospectors at the School of Mines of the University of Idaho, which opens on January 5 at Moscow. Courses offered are: elementary surveying, assaying, mineralogy, mining geology, chemistry, mining machinery, gold milling, placer mining, the cyanide process, concentration and smelting of ores, and mine bookkeeping. There are no entrance requirements and no charge for tuition. The only cost is board and room at Moscow, from \$6 to \$8 per week.

##### SHOSHONE COUNTY

The Bunker Hill & Sullivan company paid dividend No. 183, amounting to \$65,400 on December 4, making a total to date of \$13,911,750. Construction of the Washington

Power Co.'s line to the Nabob mine on the east fork of Pine creek is being pushed ahead, and 50 men are employed on the four miles of country through which it will pass. Twenty men are working at the mine, and development is to be started at once. The Blue Star company operates a group of claims one mile up Little Pine creek, and development consists of an adit 600 ft. long and several open-cuts. A compressor will be installed and more men employed.

## MONTANA

### SILVERBOW COUNTY

To satisfy a judgment of \$200,000 obtained by the Lincoln Trust Co. of New York, as trustee December 15, 1906, the holdings of La France Copper Co., in Butte, organized by F. A. Heinze, were sold on December 3 to T. S. Crotey, of New York, for \$100,000. The buyer represented a newly organized La France Copper Co. The November production from all mines was 418,260 tons of ore and 27,937,680 lb. of copper, of which the Anaconda yielded 9,882,000 lb. from 162,000 tons, and Boston & Montana 6,944,600 lb. from 106,840 tons.

## NEVADA

### ESMERALDA COUNTY

The principal mining companies of Goldfield and Esmeralda county united in an action last week against the state and county to prevent the attempt to collect taxes on patented mining property. The amount involved in taxes is \$3700 on claims assessed for \$91,000. From the law it appears that an assessment has been levied on all patented claims at \$500 each in the county. This case was argued before P. J. Sowers, judge of the District Court, who, in an opinion that was closely followed by the Supreme Court, ruled that the claims were non-assessable, and issued a perpetual restraining order against the County Clerk and ex-officio tax collector stopping him from collecting taxes on any patented mining claims in Esmeralda county or from advertising the same as delinquent.

### LINCOLN COUNTY

The Prince Consolidated company has resumed shipments of tailing from the Bullionville dump, and is also sending out 400 tons of ore per day; while the Day-Bristol is shipping 100; Mendha, 100; and the Highland Mary, Home Run Copper, and others bring the average to about 700 tons per day. The Day-Bristol will build an aerial tramway from the mines at Bristol to the ore-bins of the railroad at the Day mine, slightly over two miles.

### STOREY COUNTY

The Monte Cristo mine, owned by the Mexican company, has enough ore in sight to pay for the erection of the aerial tramway now being constructed from there to the Mexican mill, through Seven-Mile canyon. During the week ended December 7 the Mexican mill treated 492 tons of ore averaging \$26.52 per ton, with 92% extraction. At the Sierra Nevada the new air-pipe is in place, and work was resumed at the 2500-ft. level. From the raise four mine-cars, worth \$133 per ton, and 12 worth \$14, was saved. At the Consolidated Virginia a new drift has been started. The southwest drift on the 2500-ft. level of the Ophir is now being driven south into the Consolidated Virginia, the face being in porphyry. The Crown Point mined 529 cars of ore worth a total of \$5700. At the C. & C. pumping shaft all is in good order. There are fears in Nevada that the assay office at Carson City may be closed, as the United States Congress made no appropriation for it and other offices.

### WHITE PINE COUNTY

Eight shovels are working on day shift and three at night at Copper Flat, from which the daily output is about 9000 tons. The Nevada Northern is operating eight or nine trains per day, and has four hauling and one unloading crew in the service. At the concentrating plant at McGill, eight sections are working. The Giroux company has several hundred men at work again, but has not resumed ore shipments.

## NEW MEXICO

### GRANT COUNTY

The copper output of the Chino mine in November was 4,117,020 lb., making 25,174,000 lb. for the eleven months of the current year.

What is thought to be an extension of the Queen lode has been uncovered by D. L. Cresswell in his claim 7 miles south of Steins. This lies about 200 ft. west of and across

CHINO MILL.

the gulch from the Queen shaft. A force of Mexican miners is at work, and good oxidized copper ore has been opened.

### LUNA COUNTY

W. L. Bradley, an El Paso mining man, who has been working in the old Victoria district west of Deming, has acquired the Rambler mine, adjoining the Excess, which has produced over 1000 tons of lead carbonate ore. These properties are part of the old Hearst group, worked in 1882 and later, and have yielded over \$200,000. Pumping and hoisting machinery is to be installed, and the mines prospected at depth.

## UTAH

### JUAB COUNTY

At the Centennial-Eureka, owned by the United States Smelting company, the orebody on the 1800-ft. level has flattened, and this is being followed and a large tonnage mined. The Midvale concentrating plant of the company has been closed down, the first time for three years, so it will be overhauled. Within a few weeks the usual tonnage of silver-lead ore will be coming from Bingham.

The Eagle & Blue Bell has a large quantity of good ore opened on the 1350-ft. level, which has been followed 116 ft. below. The weekly output is 600 tons of ore from the mine. New machinery at No. 1 workings of the Iron Blossom has been started. It consists of a Nordberg hoist driven by a 300-hp. direct-connected motor. Good copper ore is being mined on the 2200 and 2300-ft. levels of the Grand Central. The Swansea has closed down indefinitely.

### SALT LAKE COUNTY

Fourteen of the largest water-power electric plants in Utah, Idaho, and Colorado have been merged in a \$40,000,000 corporation, which will supply railroads, mines, mills, and smelters with power. D. C. Jackling is president of the new company, whose headquarters will be at Salt Lake City. The new company includes the Telluride Power Co. and Ames & Ilium hydro-electric plants in San Miguel county, Colorado; Durango Gas & Electric Co., Colorado; the Grace plant, Bannock county, Idaho, and the Knight Consolidated Power Co., Utah. In all there are 17 hydro-electric plants with a total of 60,000 hp. and 997 miles of transmission lines.

The miners' strike at Bingham is practically a thing of the past, as previous to it starting the Utah Copper Co. had 1900 men and now has 1500 men employed, while the tonnage handled is equal to that formerly treated. The Bingham Amalgamated adit is now in 1400 ft.

At a trial of the 12-in. Karns tunneling machine at Salt Lake during the latter part of November, it was turned full

speed against a hard, tough rock, and drove 11 inches in 13 minutes, equal to 51 inches per hour. A large crowd watched the performance, and were surprised. Representatives of the machine company say that it will reduce tunneling costs 50 per cent.

## CANADA

### BRITISH COLUMBIA

The mines of the Kootenay district are said to be in better order than ever, which also applies to the Slocan district. The Eureka and Slocan Star mines are opening well. With the Standard dividend of \$50,000, the total paid this year by five companies in the Kootenay and Boundary districts is \$1,032,512. Spokane capitalists have offered \$100,000 for the Rio Tinto group of mines, but the owner has refused it.

During October La Rose income totaled \$161,399, expenses \$64,307, and net profit \$97,092. The surplus now stands at \$1,658,881. The Beaver Consolidated shaft is down 700 ft., and is the deepest at Cobalt. A large station is to be cut out, and cross-cutting started.

### ONTARIO

Conditions at the mines have changed little. The union has published a scale of wages for millmen, which is as follows: Shift-bosses, \$4.75; amalgamators, \$4.25; helpers, \$3.75; battery-men, \$4; helpers, \$3.75; concentrator men, \$3.75; filtermen and helpers, \$3.50; crushermen, \$3.75; solution-men, \$4; repairmen, \$3.75; mill sweepers, and all other classes of unskilled labor, \$3.50 per 8 hours, and includes the regular provisions regarding board. It is stated that the backbone of the strike has been broken by the strike-breakers sticking to their work at the Hollinger. A special train brought in about 50 men for the Dome mine, while other mines are adding to their working forces daily.

## MEXICO

### CHIHUAHUA

(Special Correspondence.)—At El Rayo Mining & Development Co., construction work has been started on the new aerial cord-wood tramline, and all material is on the property. It should be in operation in February and will cut the cost of wood by one-half. The line will be of the Otto friction-grip type, 11,770 ft. long, made by A. Leschen & Sons. Wood will be transported from the Provedencia valley to Los Azules, crossing a high range of mountains. Notwithstanding the fact that many mines are shut down in the Parral district, labor is scarce, especially peon labor. Cold weather also interferes with this camp, there having been two snow storms this year. Peons prefer Parral to spend the winter in as it is 2000 ft. lower than Santa Barbara.

Santa Barbara, November 27.

### GUADALAJARA

During October, El Favor Mining Co., one of the Makeever enterprises in the Hostotipaquillo district, shipped 298 tons of high-grade ore to smelters, and milled 637 tons at the mine. Estimated value of the former was \$30,717, and the latter \$12,510, and the net profit \$24,023. The mill also crushed a total of 1765 tons of mixed ore from the El Favor, Mololoa, and Mirador mines, all Makeever properties, the value being \$44,205. These mines are in charge of Walter Neal.

The Mexican Mines Co. owning the old Bolanos mines, in the Bolanos district, is resuming operations. This company is controlled by the Bradbury interests of Los Angeles, California. Power for the company's plants may be supplied by the Chapala Hydro-Electric & Irrigation Co. of Guadalajara.

### OAXACA

Not less than 25 villages have been destroyed in this state during the latter part of November by government troops. The administration believes that the rebellion in this locality has been cowed by the warfare waged, and sanctioned orders for the retirement of the greater part of the Federals from the state. Over 500 Indians have surrendered. Generally there is little improvement in the sit-

uation, in spite of the summary powers allowed the Federals.

### SONORA

During October the El Tigre old mill crushed 2804 tons of ore; the stamp-mill crushed 3710 tons; while the cyanide plant treated 6291 tons of current and 1583 of dump tailing, with a total yield worth \$157,332. Mining and development cost \$16,372; treatment, \$31,736; and the estimated profit for the month was \$77,840.

The Victor and Guerrero mines have been reported on by A. T. Bird of Nogales, Arizona. They are situated about 12 miles west of Cananea, in the Cerro Jorota, a prominent elevation at the north end of the Sioux mountains, the Victor being at an altitude of over 5000 ft. The Guerrero lies at the foothills, about one mile east of the Victor. The general country rock is andesite, and through each property is a well defined lode, over 20 ft. wide, and highly mineralized. Not much work has been done on the properties, the total being about 2000 ft. There is plenty of timber and water available.

## NICARAGUA

Revolutionary disturbances have prevented the Oroya Leonesa mine having a fair trial. It has not been possible to proceed with development, so that the ore reserves remain as stated in the preceding annual report, namely, 94,358 tons, averaging \$9.52 per ton, less the tonnage crushed since. A cross-cut has been driven from the main shaft to open up and develop the orebody at a depth of 105 ft. below the No. 1 adit. In a cross-cut from the winze, the Leonesa shoot, at 120-ft. depth below No. 1 adit, assayed \$16.40 per ton over 54 in. To carry on development, the company has borrowed \$170,000 from the Lake View & Oroya Exploration Company.

## QUEENSLAND

At Charters Towers the mills crushed 11,517 tons of ore: cyanide plants treated 12,897 tons of tailing; ore smelted amounted to 298 tons; copper ore produced was 110 tons; and black tin, 11 tons, the combined output for October being worth \$207,000.

## WESTERN AUSTRALIA

(Special Correspondence.)—The wages question at Kalgoorlie has been the important topic for many weeks past. The members of the various unions are to withdraw from the arbitration agreement at the end of November. There has been a good deal of talk about striking, but it may not eventuate. The opinion of local men is that, before any strike occurs, J. E. Dodd, Member of Parliament, who has always been useful in helping to settle disputes, will go to Kalgoorlie and get the unions to waive their claims for increases in wages if the minimum is adjusted, and that the Chamber of Mines will then probably increase the minimum to \$2.64 per shift. Crushings from the new mill of the Associated Northern at Ora Banda have so far shown fair costs and extraction; but the Ridgway 'turnover' filters will not treat the tonnage estimated. Four Huntington mills and three Ridgway machines were designed to treat 12,000 tons per month of kaolin ore containing veins of quartz and iron. The second run of the mill resulted in 5007 tons treated by two mills and two filters yielding \$26,000, at a cost of \$12,000 for mining and treatment, and \$3000 for development, leaving \$11,000 profit. Sampling of the Great Victoria mine at Nevoria, in the Southern Cross district is finished, by R. Hamilton of the Great Boulder Co. The price asked is \$240,000, which is high for ore averaging \$4.80 per ton. The Chaffers company is still trying to find the extension of the Horse-Shoe lodes in the Main Reef property. The New North Boulder mine, worked by a local company, has got the Rutter ore-shoot from the Oroya north block, of the Oroyo Links Co. At 127 ft. in a shaft, the lode was found to be 48 in. wide worth \$25 per ton. This shoot gave five leases \$170,000 from 4742 tons, less royalty and treatment. Sulphide ore from the North Boulder is treated at the Associated Northern mill, and recent returns total 155 tons worth \$8500.

Kalgoorlie, October 25.

## Personal

Professional men are invited to send news of their engagements and travels. Such news is interesting to friends.

H. F. DAVIS is in St. Louis.  
KEY PITMAN is in San Francisco.  
JAMES FARRAHER is at the Palace.  
W. D. WILSON is here from Los Angeles.  
ARTHUR W. STEVENS, of Boise, Idaho, is here.  
HARLEY A. SILL is at Tumco, California, examining mines.  
C. S. GREEN, of Maricopa, California, is in San Francisco.

JAMES G. BERRYHILL was in San Francisco during the week.

C. T. NICOLSON left for the East last Wednesday, on business.

H. C. MILLER, of Saginaw, Michigan, is now at Berkeley, California.

JOHN G. KIRCHEN, manager for the Tonopah Extension company, is in San Francisco.

FRANK M. ESTES has returned to Mexico City, with headquarters at 525 Mutual building.

GEORGE E. FARISH was married to Miss ELLEN DOUGLAS, at St. Joseph, Missouri, on November 28.

W. W. COLE, of Roanoke, Virginia, is here to attend the California Miners' Association convention.

F. H. PETTINGELL, of Colorado Springs, will make his headquarters at Los Angeles during the winter.

B. F. NOEHL has returned to Los Angeles after making examinations in the Kingman district, Arizona.

FRED HELLMANN will go, early next year, to Chile, where his address will be Chuquicamata via Autofogasta.

JOHN M. BROOKS, Jr., formerly of Guanajuato, is with the Cinco Minas Co., at Magdalena, Jalisco, Mexico.

Z. CUSHING was operated on for appendicitis at Honolulu recently and is recovering nicely. His return has been delayed about two weeks.

A. HULSHOFF POL left San Francisco for the Dutch East Indies on December 7, and will visit the mining districts of Sumatra and Celebes.

M. N. COLMAN has returned from Costa Rica, where he has been constructing a cyanide plant for the Panama & Costa Rica Mining Company.

A. F. FLYNT, of Tepic, Mexico, has returned to the Zopilote and Purisima mines in the territory of Tepic, Mexico, after an extended absence in the United States.

MORRIS B. SPAULDING is now manager in the Pittsburg district for the Crocker-Wheeler company, with headquarters in the Henry W. Oliver building, Pittsburg, Pennsylvania.

HENRY H. ARMSTEAD is leaving New York by steamer for Veracruz, Mexico, December 19, to make an inspection of his companies' properties in Guanajuato, Jalisco, and Tepic.

GEORGE W. METCALFE, JAMES SALLEE, H. L. WASTE, W. L. COLE, M. E. DITTMAR, S. E. BRETHERTON, I. O. JILLSON, J. B. KEATING, E. V. D. JOHNSON, and W. H. ROBERTS were Shasta county delegates to the California Miners' Association meeting at San Francisco.

J. NELSON NEVIUS, after attending the meeting of the California Miners' Association at San Francisco, left for Kennett to study the bag-house system of fume control at the plant of the Mammoth Copper M. Co., in the interest of the Los Angeles Chamber of Mines and Oil.

## Obituary

WILLIAM O. MADDEN, a pioneer in the development of Goldfield, died at that place early last week, at the age of 61. In the boom days of the Comstock he was employed on the Consolidated Virginia, and later went to Grass Valley, California, where he was superintendent of the Brunswick. At Goldfield he was superintendent of the Florence and Little Florence. Several years ago he retired from active work on account of failing health. He leaves a widow and five children.

## Company Reports

### CAUCASUS COPPER CO., LTD.

This company was formed in 1900 to acquire six properties in the Murgal Gorge district of Arlvin, Government of Kutais, near Dzanul, in the Caucasus. The authorized capital is £500,000. After years of difficulty, the company appears now to be emerging into a period of prosperity. The report covering the year ended May 31 last (Russian style) shows that the production was equivalent to 3030 metric tons of refined copper. The sales brought an income of £256,195, and the working cost was £166,019. Out of the profit, £70,044 was paid as debenture interest, and £23,779 was allowed for depreciation. James Colquhoun, formerly manager of the Arizona Copper Co., is the chairman of the board of directors, and spends a large part of his time at the mine. At the meeting of shareholders he gave many details of the operations. The concentration plant is at present treating 500 tons of ore per day. A third unit of 250 tons capacity is being erected and should be at work early in 1913, while the order has been given for further plant that will bring the output to 1000 tons. A new aerial ropeway is being built, having a capacity of 2000 tons per day. The methods of mining have been altered. In the first place, the overburden, consisting of loose soil varying in thickness from 10 to 100 ft., is now removed by hydraulicking; second, the ore is mined from the great open-cut by the 'mill-hole' system, thus eliminating all shoveling. A new reverberatory furnace has been built, measuring 89 by 19 ft., and the waste gases are used for steam-raising. As regards ore reserve, the estimate seven years ago was 3,600,000 tons, and since then the development has about kept pace with the extraction. The finances have recently been rearranged. The whole of the outstanding profit-certificates, amounting to £500,000, together with £299,900 in options, have been surrendered and canceled. The £579,000 6% second debentures have been scaled down to 5%; and £440,000 loans have been satisfied by 5% second debentures. The issued capital of the company consists now of £500,000 ordinary shares, and there are £45,280 5% first debentures, £500,000 convertible 5% second debentures, and £745,900 non-convertible 5% second debentures. The position of the ordinary shares is therefore greatly improved. It will be remembered that the company has the advantage of the higher price of copper ruling in Russia.

### BURMA MINES, LTD.

This company was formed by Bewick, Moreing & Co. in 1906 for the purpose of acquiring ancient silver-lead mines and slag heaps at Bawdwin, near Lashio, in Upper Burma, not far from the frontier of China. The mines were in former times worked by the Chinese for the silver content of the ore, and the lead was an unconsidered item, to judge by the fact that the slag averages 45% lead. These workers confined their attention to the oxidized zone, and the sulphides disclosed by the development work done by the present company contain a large proportion of zinc. The company had to be organized in 1910 on a new basis by reducing the nominal capital, and at the same time assessing the shareholders. The issued capital now consists of 312,046 shares of 4s. each, on which £33,737 has been called up, and there are also £213,685 debentures. The report for the year 1911 shows that the affairs of the company are still being rearranged with the object of putting it on a sounder basis. The smelter has been removed from Mandalay to the vicinity of the property in order to save the expense of transport; a refinery is being built so as to extract the silver and sell the lead in the Eastern markets; while the prospecting and development work has been carried on so as to give the company a source of ore instead of being entirely dependent on the old slag heaps. The ore disclosed by development consists of mixed sulphides running high in lead and zinc, with some iron and copper, and containing much silver. The ore varies

greatly in content, but taking an average of the samples quoted in the report, it may be said to contain 8 to 20% lead, 10 to 33% zinc, 1 to 10% iron, 0 to 5% copper, and 5 to 25 oz. silver per ton. The gangue is mostly quartz. In view of the changed conditions due to the nature of the sulphide, shipments of ore have been sent to London for the purpose of determining the best method of treatment. During the year the smelting plant at Mandalay treated 34,340 tons of slag averaging 45½% lead and 2.62 oz. silver, also 2589 tons of Bawdwin ore, and 816 tons of purchased ore. After the removal of the smelter to the mine, 1019 tons of slag and 600 tons of ore was smelted. The total bullion produced amounted to 13,756 tons. The receipts from its sale were £181,296, and the cost of mining, smelting, and administration was £148,804. Out of this £5658 was allowed for depreciation, and £12,821 was paid as debenture interest. The net profit was £15,126, which was carried forward.

### TOMBOY GOLD MINES CO., LTD.

The report of the general manager, D. A. Herron, gives details of work for the year ended June 30, 1912. At the Argentine group of claims there has been no advance in development, not due to lack of promising prospecting ground, but owing to the desire of getting the newly acquired Montana property on a producing basis. Development will be resumed on the ore-shoot of the former near 119 manway below the 2100-ft. level, and a block of ground above this level. A year's work at the Montana has confirmed the original estimate that no extra equipment, other than an air-compressor, would be required. Montana ore is transported over the covered surface tramway connecting the portal of the Ophir tunnel with the portal of the 1750-ft. level of the Argentine mine, hoisted through the Cincinnati shaft 90 ft. to the 1650-ft. level, and then trammed to the 60-stamp mill. The Ophir level of the Montana has been equipped with a new track and extended north 300 ft. and sidetrack 250 ft. long constructed near the present face. A large amount of dead work had also to be done before ore could be mined. Owing to the variable metal content of the ore, as well as the size of the vein, it has been difficult to estimate reserves in the Montana mine, but the original tonnage has been increased and the mine is supplying 30 stamps with ore, and 21,702 tons averaging \$10.50 per ton in gold and silver was treated. Montana ore assays: gold, 0.42 oz. per ton; silver 4.3 oz.; lead, 1.68%; zinc, 2.21%; iron, 4.52%; and copper, 0.43%. In the Argentine mine ore reserves are estimated at 340,000 tons, there being 230,000 broken in stopes. The mill has been altered and improved by Gelasio Caetania with good results, details of which will be published in another issue of the *Mining and Scientific Press*. The year's operations may be summarized as follows:

Ore treated, tons .....	107,577
Yield from—	
Ore .....	\$401,432
Concentrate .....	520,688
Pulsator classifier .....	32,861
Total production .....	\$954,981
Average per ton .....	\$8.87
Costs:	
Mining and development .....	\$2.20
Milling .....	1.90
General .....	0.59
Total per ton .....	\$4.69
Profit for year .....	\$450,941
Dividends paid .....	\$148,800
Carried forward .....	\$54,600

SOUTHERN RHODESIA is in need of a thoroughly comprehensive geological survey by skilled field observers. So far, prospecting has been conducted on haphazard lines and there has been little really systematic exploration along mineralized belts.

## Concentrates

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

**M**ARBLE valued at \$6,992,779 was produced in the United States in 1911.

**T**HE value of all the gold produced in the United States from 1792 to the end of 1911 is estimated at \$3,358,463,500; and value of silver at \$1,629,972,000.

**P**OTASH deposits may not be located under the law governing salines, as erroneously stated in this column recently, but fall instead under the general placer law.

**C**ARBORUNDUM is more effective than emery in polishing sections of metal, or in grinding thin sections, as a lessened pressure is required and the time necessary is greatly shortened.

**E**ROSION in bronze propeller blades has been found to be greatest where the change of rate of flow is greatest, such as in bends or curves where the water suddenly changes its direction of flow, or notches in the blades where the current is converted into a jet-like stream.

**T**HE known coalfields of the United States embrace an area of 310,296 square miles, the estimated supply of coal before mining began was 3,076,204,000,000 short tons, of which 1,922,979,000,000 tons were easily accessible, and 1,153,225,000,000 accessible with much difficulty.

**H**AIR silver frequently occurs in nature, and its formation is supposed to be due to the fact that  $\text{Ag}_2\text{S}$  is capable of existing as gas to some extent. The metal, as it separates from the gas, is in a condition intermediate between the gaseous and solid, resulting in the formation of fine threads of the metal.

**C**ORROSION of track fastenings on zinc-treated railroad ties is apparently caused by evaporation around the spike head of water containing zinc salts from the unseasoned ties. Steel spikes are more affected than wrought iron, and corrosion is prevented by seasoning the ties by zinc-tanning treatment, or by crude oil.

**A**LLOYS, as a rule, do not solidify at a definite temperature, but over an interval, sometimes of quite wide range, in which the mass consists of solid grains in a fluid melt. Expelling this liquid by means of a centrifuge, by an inert gas, or by liquid such as oil, yields a porous metal. Thus from an alloy of 90% lead and 10% tin, porous lead can be obtained.

**W**ATER has been a source of expense and loss to many a mining company, but the Bullion Coalition company, in the Stockholm district of Utah, finds profit in it. Below the Honerine drainage adit, owned by this company, is a fertile valley in which the mining company is now raising fine crops on a ranch of 1250 acres irrigated with waste water from the mine.

**F**ATAL accidents in coal mines of the United States in 1911 totaled 2719, of which 1321 were due to falls of roof, 'slate,' or coal; mine cars and locomotives, 438; gas and dust explosions, 362; powder and other explosions, except gas or dust, 134; electrical, 94; mine fires, 80; and all others, 290, showing that the first mentioned causes more deaths than do explosions.

**L**EAD objects in museums sometimes gradually decompose, leaving a powder chiefly of  $\text{PbCO}_3$ , while other objects do not change. Investigation has showed that more or less chloride was present in the 'sick' lead. To test the

matter, lead foil was allowed to remain in neutral 30%  $\text{NaCl}$  solution and then kept dry. After 3 years the metal was whitish and had gained 0.0517 gr. in weight. Painting the objects with a collodion varnish did not prevent further destruction and long washing with water proved useless.

**S**UBLIMED WHITE LEAD contains 75% of lead sulphate, 20% of lead oxide, and 5% zinc oxide. Blue lead contains 50 to 53% of lead sulphate, 38 to 41% of lead oxide, with small proportions of lead sulphide and sulphite, and zinc oxide. Zinc-lead oxide contains from 46 to 50% of lead sulphate, 46 to 52% of zinc oxide, and a small amount of zinc sulphate. Leaded zinc oxide may vary from 4 to 20% in lead sulphate, the remainder being zinc oxide, with a little zinc sulphate. Sublimed white lead and sublimed blue lead are produced directly from ore.

**E**XPLSION-PROOF as applied to a motor refers to one inclosed in a casing so constructed that an explosion of mine gas (methane), and air within the casing will not ignite a mixture of the same gas surrounding the motor. Out of 248 tests made by the Bureau of Mines at Pittsburg with a motor at rest, a 'puncture' occurred four times. By the term 'puncture' is meant the ignition of the gaseous mixture surrounding a motor casing by flames discharged from it. Twenty tests with a motor running showed no 'puncture.'

**M**INING property can be protected from liens when under option. Section 1192 of the California Civil Code provides that every building or other improvement or work (including labor and materials furnished for or upon mining claims or in milling or reducing the ores from the same), constructed, altered, repaired, performed, or furnished upon any land with the knowledge of the owner shall be held to have been constructed, altered, repaired, performed, or furnished at the owner's instance and the owner's interest in such land shall be subject to a lien for the same, unless he, within ten days after having obtained knowledge of such construction, alteration, repairs or work or labor, gives notice that he will not be responsible for the same by posting a notice in writing to that effect in some conspicuous place on the property, and within the same period recording with the court recorder a verified copy of said notice. Such notice of non-responsibility should contain a description of the property affected sufficient for identification, with the name and nature of the title or interest of the person giving the same. The copy to be recorded may be verified by anyone having a knowledge of the facts, on behalf of the owner or person for whose protection the notice is given.

**S**CUUM floating upon the surface of stagnant water is commonly regarded as an indication of the presence of petroleum, but is usually only an evidence of the presence of soluble iron salts. Iron in the form of oxides is contained in most rocks and soils. Percolating waters which are charged with  $\text{CO}_2$  have the power of dissolving one of these oxides,  $\text{FeO}$ . The water containing ferrous carbonate in solution oozes from the rocks and collects in pools or swamps, where it absorbs oxygen from the atmosphere. By this process the ferrous carbonate is converted into an insoluble peroxide ( $2\text{Fe}_2\text{O}_3 \cdot 3\text{H}_2\text{O}$ ). The peroxide is deposited in an excessively fine form as a scum on the surface of the water. This has a beautiful play of color and reflected light, and much resembles a film of oil, for which it is often mistaken. The precipitate later sinks to the bottom because of its heavy specific gravity, and there collects as a reddish mud, thus allowing a fresh supply of oxygen to produce another scum on the surface. If some of the scum is inspected under the microscope it will be noticed to contain a number of iron-secreting vegetable organisms called *Gallinca*. A simple way to decide whether a scum on water is oil or precipitated oxide of iron is to place a little of it in a tube and add a few drops of acid. If it is iron oxide it will readily dissolve.

## Book Reviews

Any of the books noticed in this column are for sale by, or can be procured from, the MINING AND SCIENTIFIC PRESS.

**CYANIDE PRACTICE IN MEXICO.** By Ferdinand McCann. 194 pp. Ill., tables, plans, index. Mining and Scientific Press, San Francisco, 1912. For sale by the *Mining and Scientific Press*. Price, \$2.

If it were not for the cyanide process, mills in the great Waihi, Mexico, Tonopah, and Cobalt districts which produce silver ores, would probably be still using the old Washoe or patio process. Results from cyaniding these ores surprise many millmen, and in the volume under review there is a comprehensive review of metallurgy in Mexico, including the districts of El Oro, El Tigre, Guanajuato, Parral, and Pachuca. In part this book consists of extracts from one written and published by the author in Spanish and hitherto not accessible to those who do not read that language. To this has been added new matter to bring the practice in various Mexican mills up to date.

Every work on cyanide practice has a more or less detailed summary of the process, and this one has an historical outline to 1906 in readable form. Chapter II discusses shortly what systems of treatment are suitable for different classes of ore, from crushing to filtering the final slime. Eleven chapters are devoted entire to descriptions of the principal plants in Mexico, including a large valuable table prepared by W. E. Hendy, giving details of plant, equipment, and metallurgical practice at five mills in Mexico, and eleven in South Dakota. This particular table practically makes a full description and flow-sheet combined, and is useful for reference. Several of the descriptions mentioned in chapters III to XII are greatly condensed and are to that extent better than those drawn-out in many journals, tending to make reading tiresome. Mexican practice may be summarized as follows: The ores are mainly valuable for the silver which they contain. This ranges from 10 to 180 oz. to 1 of gold, save at the El Oro mine, where the contents are gold \$8.06 and silver 3 oz. per ton. Stamps vary from 1100 to 1250 lb. weight, and nowhere has the heavy stamp craze influenced local practice. Crushing is done in weak cyanide solution in all cases, and while on this subject it might be as well to note that the use of hot solutions as used profitably at Tonopah, where the ores carry 100 of silver to 1 of gold, is not mentioned. Crushing in 60 to 80°F. solution and raising it to from 95 to 120° in the agitator is the scheme at Tonopah. Is this of no benefit in Mexico? Concentration is necessary on some ores in Mexico, and this product is shipped away for treatment. Several mills make a sand and slime, treating the former by percolation for about 9 days and the latter by agitation, decantation, and filtration in Burt, Butters, Moore, Kelly, or Merrill filters. The practice of adding hard rough ore to tube-mills for grinding pulp obtains at two plants; but the efficiency of this procedure has been questioned. Mechanical agitators are often used, as well as the Pachuca vat. Precipitation is in the majority of cases by zinc-shavings, while clean-up procedure varies according to experience, acid treatment of precipitate not being general. Extraction varies from 94.18% of gold and 78.56% of silver at the El Oro mill, to 95 and 90% respectively at the Guerrero mill of the Real del Monte y Pachuca Co., Hidalgo; while costs are from \$1.14 to \$4.04 per ton; and consumption of chemicals at the latter being 2.75 lb. of cyanide, 9.9 lb. of lime, 0.4 lb. of lead acetate, and 1.1 lb. of zinc per ton treated.

The account of the new mill at the Esperanza mine is accompanied by an elaborate yet simple flow-sheet. Two classes of ore are treated, sulphide and hard oxidized, the former being crushed to ¼-in. size and fed to 15 Huntington mills, which crush 15 tons per day each through 60-mesh slot screen, giving 60.7% through 200 mesh, at a consumption of 13 hp. The 1½-in. oxidized ore is crushed by 120 stamps of 900 lb. each, with a daily average of 3.4 tons each. Sulphide ore is concentrated, while all pulp is ground in tube-mills, agitated in Pachuca tanks, and the flocculent slime from primary classifiers, and granular slime from re-ground

sand is treated in Merrill filter-presses. An interesting comparison between Chilean mills and stamps is to be found in chapeer VIII, the Loreto mill of the Real del Monte company having both at work, while at its new Guerrero mill there are stamps crushing through 4-mesh screens, followed by Chilean and tube-mills, similar to the work at the Goldfield Consolidated. This is of interest, as this type of mill is being much discussed of late for primary crushing or re-grinding from stamps, etc. The first place that the Pachuca vat was tried on the American continent was at the San Francisco mill at Pachuca, and full details are given in chapter X. The Lucky Tiger-Combination mills treating a complex ore are to be improved early in 1913, and their present work is described, showing the work of Kelly filters. Some discussion has appeared in technical journals on the Pachuca and Parral systems of agitation, and Bernard MacDonald gives a comparison of results at Parral. Chapters XIV to XVIII deal with 'Cyanide Practice in Small Plants'; Continuous Cyanide Treatment, in Connection with Pachuca Tanks'; 'Cyanide in Pan-Amalgamation Mills'; 'Precipitation on Metallic Zinc'; and 'Treatment of Cyanide Precipitates,' all of which are thoroughly detailed in a useful manner. Altogether, 'Cyanide Practice in Mexico' is undoubtedly a useful addition to the existing literature on cyaniding. Many works attempt too much in this line; but this one has not covered too wide a scope, and as a result is worth while. It is especially valuable in that it gives in condensed form the actual practice and actual results in a large number of modern mills. The book is well printed and illustrated and forms an excellent companion volume to 'Recent Cyanide Practice' and 'More Recent Cyanide Practice' published by the same firm. M. v. B.

**MODERN MINE VALUATION.** By M. H. Burnham. 160 pp., tables, and diagrams. Charles Griffin & Co., London. For sale by the *Mining and Scientific Press*. Price \$3.75.

Much of the material in this book was previously published in *The Mining Magazine* in a series of articles entitled 'The Finance of a Mine,' and provoked interesting discussion by H. S. Denny, W. H. Goodchild, Ross B. Hoffmann, S. J. Truscott, and others who took exception to some of the author's contentions. The author has evidently profited by the discussion to amplify or clarify some of the principles advanced. While there is much in the book that will commend itself to the more advanced engineer and investor, and will be a welcome addition to what has been published on mining finance, there are a number of engineers who will not agree with the author and who do not believe that the valuation of future possibilities of a mine can be expressed by any general mathematical formula, however ingenious. In most cases of uncertainty of persistence of metal content and tonnage in depth, such practice, in my opinion, attempts to introduce a refinement of calculation that is not warranted by the speculative conditions. In a mine, for instance, where the greater part of the value is speculative and dependent upon extension beyond present openings, any refinement of valuation methods is absurd. It is for the engineer clearly to state the facts and the risks of the enterprise, and his conclusion regarding possibilities and advisability of taking hold. It is for the investor to judge if the reward in case of success is large enough in proportion to the amount risked to make it an attractive venture; in other words, if the game is worth the candle. While the more careful engineer of today applies the principles, if not the formulæ, of valuation advocated by Mr. Burnham, there are a number of engineers who occupy more or less prominent places that might benefit by a careful reading of the book, though their clients might object to these methods being applied to their next flotation. As the author says, the practice and principles of valuation generally observed leave much to be desired, and his demand that a clear and full presentation of data and deductions therefrom be embodied in a report cannot fail to meet with approval. Engineers following this method and with a clear idea of mining finance are "too few in number, unknown to many, and have a status only as special advisers

to the larger and more reputable concerns. Their light often has a bushel kept carefully over it lest the public, learning of their existence, should demand favorable reports from them on new ventures."

A number of pages are devoted to explain the author's system of sampling. This was devised to meet the needs of systematically sampling certain veins on the Rand, and is more particularly intended for large veins of banded structure. Careless work in sampling is always to be deplored, but for ordinary examinations and with small veins it is hardly necessary to go to such extremes; such procedure would seem an unjustifiable affectation of accuracy. But to do Mr. Burnham justice, one must quote: "A sense of economic proportion should be preserved even in examination work." What the author means is fortunately explained in a footnote as follows: "This is a more euphonious way of stating that common-sense on the ground as well as in the choice of sampling and calculating systems is a useful adjunct to accuracy." A number of tables that show considerable thought and labor in their preparation will prove interesting, though many of them are, as the author says, "old friends," and there is much in the book that is commendable. It is well worth reading by engineers, though promoters in general and those engaged in questionable and top-heavy flotations are not likely to recommend the book to investors. C. J.

## Catalogues Received

McKIERNAN-TERRY DRILL CO., 115 Broadway, New York. Bulletin on Pile Hammers. 28 pages. Illustrated. 6 by 9 inches.

CENTRAL FOUNDRY CO., 90 West street, New York. Booklets showing advantages of Universal Pipe. Illustrated. 3½ by 6 inches.

SNOW STEAM PUMP WORKS, Buffalo, New York. Bulletin S-110, 'Snow Crude Oil Engine.' 8 pages. Illustrated. 6 by 9 inches.

HINMAN HYDRAULIC MFG. CO., Denver, Colorado. Catalogue No. 12-A, 'Canal and Reservoir Appliances.' 36 pages. Illustrated. 10 by 7 inches.

THE HAYWARD CO., 50 Church street, New York. Pamphlet No. 596, 'Hayward Buckets and Digging Machinery.' 8 pages. Illustrated. 6 by 9 inches.

ALLIS-CHALMERS CO., Milwaukee, Wisconsin. Bulletin No. 1804, 'McDougall Roasting Furnaces.' 12 pages. Also Bulletin No. 1628, 'Hydraulic Turbines.' 16 pages. Illustrated. 8 by 10 inches.

NONPAREIL HIGH PRESSURE COVERINGS. 71 pp., ill. The Armstrong Cork Co., Insulation Department, Pittsburgh, 1912. An interesting booklet describing losses in steam pipes; how to cover pipes with Nonpareil compound; and general results from properly insulated pipes. This is an important subject in all steam plants, and is well treated in this publication.

## Commercial Paragraphs

The ALBERGER PUMP & CONDENSER CO., of 140 Cedar street, New York, announces that it now owns the exclusive right to manufacture and sell the Hammond meter. This meter has been largely used in power-stations for keeping an accurate record of boiler feed. It is also adaptable for measuring other fluids, and is ideal for use in modern industrial plants.

The H. W. JOHNS-MANVILLE CO. has recently opened a new Southern warehouse at 31½ South Broad street, Atlanta, Georgia. The entire building, embracing three floors and a basement, with a total floor area of about 10,000 sq. ft., will be utilized exclusively as a warehouse for a stock of such J.-M. products as roofing, boiler and pipe coverings, cements, packings, fire extinguishers, electrical, railway, and automobile supplies.

## Decisions Relating to Mining

Specially reported for the MINING AND SCIENTIFIC PRESS.

### OIL AND GAS LEASE—RIGHTS OF SURFACE OWNERS

The lessee under an oil and gas mining lease cannot select a place and there drill an oil or gas well if the particular place selected will endanger the property and lives of other people who are lawfully using the surface, when the lessee can drill his well at another place equally convenient to him, and equally advantageous to him, which will not endanger the property and lives of those lawfully upon the surface.

Gulf Pipe Line Co. v. Pawnee-Tulsa Petroleum Co., (Oklahoma) 127 Pacific, 252. October 15, 1912.

### AGRICULTURAL LEASE DOES NOT GIVE MINERAL RIGHTS

Where a lease contained the operative words, "demise, set and to farmlet," without any words in any part of the lease referring to minerals on the premises, it was held to be a lease for agricultural purposes only, and not to convey any mineral rights. Where the lessee in possession under such a lease mines coal and makes passageways, he cannot be permitted to continue trespass on plaintiff's premises by having such passageways to mine coal from other lands.

Trustees of Proprietors of Kensington v. Lehigh Valley Coal Co., (Pennsylvania), 84 Atlantic, 820. May 6, 1912.

### EXTRALATERAL RIGHTS

Held as a matter of fact that the so-called 'fault vein' of the National Mines Company was a continuation of its principal vein, and that the principal vein and its continuation as aforesaid crossed both end lines of the National company's claims, and did not turn and cross the side lines of the Charleston Hill claims as had been unsuccessfully contended by defendants. Hence the National Mines Company was entitled to an extralateral right on its vein beneath the Charleston Hill Syndicate claims.

National Mines Co. v. Charleston Hill National Mining Syndicate et al., (Nevada) United States District Court. November 1912 (not yet reported).

### PLACER CLAIMS IN ALASKA—NEW REGULATIONS

To meet with the requirements of the new Alaska placer law (in effect August 1, 1912), the Land Department has issued the following instructions:

(a) Where location is made by agent or attorney, the power of attorney must be in writing, executed and acknowledged in accordance with the laws of Alaska or of the state in which it is executed, and recorded in the proper recorder's office. The application for patent must be accompanied by a certified copy of such power of attorney, showing its recordation.

(b) An agent or attorney cannot at one time represent more than two individuals or one association, and he may make not exceeding two placer locations for each of his principals during any one calendar month. The application for patent should accordingly be accompanied by a sworn statement of the agent setting forth specifically the names of all placer locations and locators thereof, made by him under his powers of attorney during the month in which the claim for which patent is sought was located.

(c) No person can through an agent or for himself locate more than two placers in any calendar month. Accordingly the application for patent should be accompanied by a specific statement of each principal locator showing all locations made by him in person or through agent or attorney during the calendar month in which the claim for which patent is sought was located. This showing must be made in addition to that hereinabove required of the agent himself.

(d) No survey of any claim will be approved which shows an area in excess of forty acres or a length of more than three times its greatest width. These instructions apply only to placers located in Alaska subsequent to August 1, 1912.

Land Department Circular. October 29, 1912.

## EDITORIAL

**B**ULLETS and dollar diplomacy are not always the most important factors in international relations. Germany is reported to have halted its attack on the Standard Oil Company because the naval department urges the desirability of keeping on good terms with American producers of crude.

**M**ONTANA is seldom thought of as a gold-producing state, since the precious metal content of its enormous output of copper has no visible existence until reaching the refinery at Perth Amboy. But the yield of small producers is also considerable, as our Butte correspondent elsewhere notes.

**A**NONYMOUS contributions will not be printed in this journal, and it seems necessary periodically to repeat this statement. When for any satisfactory reason an author does not care to have his name known, a pen name may be substituted, provided always that the real name be given the editor as evidence of good faith. If 'One of the Great Unwashed,' an anonymous correspondent of ours, will send us his name and address, we shall be glad to print his contribution.

**F**URTHER correspondence between Mr. F. W. Mondell and the Secretary of the Interior relative to sales of coal land in Wyoming by the Federal Government, recently made public, emphasizes the fact that the prices now charged do not prevent sales for development and are materially less than those that form the basis of transfer of privately owned lands. Allowing ordinary interest and taxes and a reasonable rate of production, the heaviest charge made is equivalent to a royalty of two cents per ton, whereas the courts found in the Owl Creek case that 6½ cents was a fair average for Wyoming royalties.

**A**GITATION concerning smelter fume has been the direct source of much loss in California. The decreased output of copper last year as compared with two years ago, corresponding to a decrease of nearly \$3,500,000 in value of the mineral output of the state, is in large part attributable to this factor. It is interesting to note that the total value of the real estate in Shasta county is but little more than twice this sum, and the single company now in operation there annually expends a greater sum upon the removal of solid particles and neutralization of its fume than would cover the total damage done to agriculture by all the plants since the beginning of smelting operations in the district. The Los Angeles Chamber of Mines and Oil, with characteristic and commendable energy, has sent Mr. J. N. Nevius to study the conditions in Shasta county, with a view to proposing legislation at the next session of the state legislature which will do away with the present continual unrest. Such action is extremely wise. The smelting companies have so far confined their efforts to resisting unjustifiable attacks upon them, and it is high time to take the attitude that smelting is a necessary and well established art which must, for the general good, be permitted to flourish under no more than reasonable restrictions. At present, farms yielding a few thousand dollars per year can shut down a smelter yield-

ing millions. The smelters make every reasonable effort to prevent damage; some have moved their plants to points remote from possible damage and others have gone to great expense in the use of methods of prevention, yet every tree that dies in the county forms a possible basis for a damage suit. The smelters recognize the principle that every industry should bear all the damage incident to its conduct, and are willing to pay reasonable compensation for every authenticated case of injury. Let us have legislation providing for the determination of damage by capable non-partisan men, award upon a reasonable basis, and opportunity to carry on in security an industry which is almost as ancient and no less necessary than the agriculture with which it sometimes interferes.

**C**HRISTMAS, according to commentators on the obvious, comes but once a year. There can be no successful contradiction of this dictum, if attention be centred on the day rather than the spirit. There is but one twenty-fifth of December in each year, save for those who cross the date line opportunely, but Christmas is more than a particular day. It, like the City of the Hub, is a state of mind. More than that it is a spirit—a spirit of joy, of kindliness, of hope. Not the calendar, the Christmas tree, the hung stocking, or the deluge of gifts, makes Christmas. Like salvation, if you do not feel it, it exists not for you. If, however, you have the wish and the will to widen a little the limits of happiness, if you pause a bit to think of others, if you realize that the *mozo* who serves you or the 'hunkie' in the bunk-house is after all a brother human—one who has feelings, hopes, ambitions mayhap, that differ from your own but are dear to him—if you are touched with the feeling of brotherhood, then Christmas has come to you, and we could wish for you nothing better than that it come not once a year only, but to sweeten and hallow the whole of the twelve-month.

**U**NPREPAREDNESS has again resulted in loss of life. The account of the fire at Mount Lyell given by our Melbourne correspondent is but a repetition of what has happened many times elsewhere. The management had all the usual safeguards, but had not planned for the unusual. A little fire is a dangerous thing, and nowhere more so than underground. Metal miners, free from the dangers of dust and gas explosions that menace coal miners, forget that the burning of a small amount of wood in the limited space open in a drift or stope, will exhaust the oxygen of the air in a surprisingly short time. Men are suffocated before they are aware there is danger. The confined spaces also make fire-fighting difficult even when apparatus is at hand. Constant watchfulness and a liberal supply of fire extinguishers is the best protection. It is peculiarly true of underground fires that the proverbial ounce of prevention overbalances the pound of cure. A number of the large companies now maintain a regular fire patrol through their mines. At the Tonopah Belmont mine these firemen have, in the past year, found and extinguished a half dozen or more burning candle ends left in such a position as to have possibly caused a fire. Good apparatus and constant vigilance is needed. We would call attention, however, to the fact that a plan for fighting fire should also be matured. Just as the firemen in the cities make in advance plans for fighting a fire starting in any quarter, so a mine superintendent should work out plans for notifying his men, for controlling ventilation, using water lines, and for organizing rescue and fire-fighting parties. Above all else, every man around the mine should know exactly what to do when the fire signal is given. Apparatus without trained men, equipment without educated generalship, is not only useless but may increase the danger.

**O**IL-FIRING for smelting furnaces is becoming popular, and following its successful application for reverberatory furnaces at the Cananea and Steptoe plants it has been adopted at several other plants in the Southwest. Attempts at blast-furnace smelting using oil as fuel have frequently been made, those at Van Anda, British Columbia, last year being the most extensive. More recently the Pioneer Smelting Company has built a plant for full-scale work at Corwin, Arizona, but no report of the results secured in operation over any considerable period has yet appeared. Like the Irishman who believed he could get his tight boots on after having worn them awhile, new processes are more likely to be successful if tried at large plants; where they are not at all welcome, as they cause too much interference with regular work. At a small property a great variety of business and mechanical troubles not necessarily incident to a new process often seriously interfere with its success, while the difficulties of the process similarly affect the business success of the enterprise. There would seem to be a possible field for oil-fired blast-furnaces, though not a large one. Throughout a large area adjacent to California the substitution of oil for coke would greatly decrease the cost of the heat units necessary. It must not be overlooked that in the blast furnace the purely physical rôle of the coke is often no less important than the heat which it furnishes, and at several plants where the sulphur content of the charge is high enough to permit smelting without the addition of coke, it is nevertheless added in order to give a more porous and faster smelting charge. A considerable increase in the tonnage smelted per day is cheaply secured at the cost of a few tons of coke. On the other hand, in a high sulphur charge the object of the smelting operation is to burn off the sulphur and oxidize and slag the iron present, operations which are not facilitated by the presence of the glowing coke necessary to furnish the additional heat that may be required. Supplying this heat through complete combustion of liquid fuel offers a considerable advantage if a satisfactory degree of porosity of the smelting mixture can be maintained. Unfortunately, the smelter is continually called upon to handle a larger and larger proportion of fine material, and it is only in rare cases that lump ore is available in abundance. The use of oil in blast-furnace smelting has to meet the inexorable conditions of low cost and high capacity; upon the degree in which it is able to meet them its success will depend.

### Geological Survey Building

Elsewhere we print an abstract from the report of the Director of the United States Geological Survey, bearing on the need of a suitable building for housing that bureau. We are glad to see the matter made prominent in his report, for we consider it one of first importance. As Mr. Smith points out, there is, aside from the constant danger of loss by fire of documents that can not be duplicated, an equally constant loss of efficiency and serious danger to health under present working conditions. No one who has wandered down the dark halls of the present building and stumbled over boxes and specimen cases while hunting for the author of some famous geological report, has failed to feel that the Government takes but little care of employees in this branch of the public service. Contrasting the cubby-hole occupied by the chief geologist with the private office of a postmaster in a town that has a political pull, emphasizes the need of change. 'Pork barrel' legislation gives beautiful public buildings to small frontier towns in Wyoming, at the expense of efficiency and health among regular employees at Washington. Mining men often complain, and justly, of the delay in writing and printing Geological Survey reports. Much of the delay may be traced

directly to the poor quarters and the crowded conditions under which the geologists and their assistants must work, and prompt issuance of reports need never be expected until suitable quarters are provided. At various times attempts have been made to obtain an appropriation for such a building, but these have always been defeated by some technicality. In 1909 plans were ordered for "a fire-proof building of modern office-building type" and an unexpended balance of \$96,506 was made available for preparing the plans. It is interesting to note that this money was available because one Western senator, Mr. F. G. Newlands, refused to receive from the Government more than he had paid for his part of a certain city block purchased as site for a Hall of Records. The clamor for this particular building died down after the site was purchased, and now the Government has the land and an unexpended balance. Plans submitted to Congress last May provide for erecting a building for the use of the Geological Survey and closely related bureaus of the Department of the Interior. These call for expenditure of \$1,950,000 for a three-story brick or \$4,900,000 for a seven-story stone building. The latter amount, as the Director pertinently remarks, just equals the value of the public property now exposed to serious fire risk in the present unsafe, crowded, and unhealthy quarters. Details as to the style of building are of minor import. A structure suitable to its intended use rather than monument is needed, but most of all Congress should be urged to end the present disgrace of expecting gentlemen and scholars to prepare scientific reports under sweatshop conditions.

### Public Lands and the States

State control of the remaining public lands is being widely urged. The California Miners' Association, after active debate, pronounced unequivocally in favor of this plan, and in doing so gave voice to a sentiment widely held throughout the West. There can be no question that, wearied with the constant friction with representatives of the Forest Service and the Land Office, those who live in the West are in large numbers coming to demand that the public lands be passed over to the states. In part this movement is based upon considerations of principle, and in part on expediency. It is maintained upon the one hand that the lands were originally ceded to the general Government in trust only, and with the purpose of having them pass as promptly as possible into the hands of actual settlers. The first public lands were given by the states to the Federal Government to be sold to pay the public debt. The states at the same time persistently refused to cede those lands that lay within their respective borders. It is argued that while the right of the United States in the public lands is on all hands admitted to be that of owner rather than sovereign, it is practically impossible for the general Government permanently to hold and administer lands which together constitute a large fraction of the area of a state, without impairing the sovereignty of the latter. Since the equality of the states is a fundamental tenet of Americans, ground is laid for strong demand that the lands be turned over to the individual states. The second argument, that of expediency, rests on the admitted fact that it is always difficult and often impossible to obtain from Congress, a majority of the members of which live outside the affected states, prompt and adequate legislation. If the matter be left to the discretion of a bureau chief or a department secretary, the result is good or bad according as the individual who administers is honest, diligent, courageous, informed, and efficient, or the contrary. In any event the action is "arbitrary"—a much abused term—and practically even the best officials are rarely free to do the best that the situation de-

mands. That this is true is as freely admitted in Washington as in the mountains. No one could condemn the present situation as regards power development, for example, more severely than has Mr. Walter L. Fisher, the present Secretary of Interior. "The present law," he states in a recent report, "neither promotes development nor protects the public interest in an effective manner," and he attributes this principally to the fact that a permit is revokable at any time without specific reason. He calls it "a serious and unjustifiable obstacle to the development and utilization of one of the Nation's greatest natural resources." He declares that conditions and limitations should be defined by statute on which permits should be issued, and only for breach of which they should be canceled. In the meantime, and pending formulation of adequate regulations or legislation, all permits are for a time at least refused. This effectually stops development, and in the West, development is the supreme good.

As against state control, two lines of argument worthy of careful consideration are advanced. In the first place many of the problems involved are interstate in character. Power used in the Goldfield and Tonopah districts of Nevada is generated in California. Granting that a measure of regulation of power companies is necessary, which state is to control? Again, use of the streams for power development and for irrigation is interwoven with the whole problem of stream control. The rights of the Federal Government in matters of navigation are admitted, and yet to regulate the streams so as to fit them for maximum use as navigable channels requires a measure, at least, of supervision over the tributaries and the sources. Admitting that forests do not influence rainfall, forest cover, using the term comprehensively, does influence stream control. In the East the problem has proved too big for the individual states, and the United States is now engaged in buying back lands at the heads of the rivers in the interest of stream control. With this teaching from experience, it seems folly to make haste in giving away similar lands in the West already owned by the Nation. The second argument is also founded on experience. At one time the general Government gave to the various states all the swamp lands within their borders on condition that they be reclaimed before passing to individual ownership. The great bulk of these lands are now privately owned and are still unreclaimed, and as part of its work of river improvement the United States Government is annually spending large sums necessary to reclaim the lands. At the same time even larger appropriations will be necessary before the work is complete. It is also within the experience of practically everyone living in the West that at various times the different states have fallen under the dominion of corporations or cliques which, under promise of development, have practically robbed the state. It is historically true that it has been easier to corrupt a state legislature than Congress, and that in the past municipal government, that nearest the people, has been the poorest in America. It is hoped that conditions have improved; that in the future all branches of the public service from City Council to Congress will be conducted on a high plane, but facts are stubborn and recruits should not be trusted oversoon. There are many, who realizing the force of the argument in favor of state ownership as a final policy, contend that the time is not ripe. There is still too prevalent a notion that it would afford but an easy way to escape regulation and compensation. State ownership may afford the only final solution, but in our judgment this, even if it be desirable, is not likely soon to be brought about, and we are therefore much more interested in securing legislation from Congress that will permit development and clearly define rights through the period, long or short, during which title continues in the United States.

# The Benguet Mining District, Philippine Islands

By ARTHUR W. GEIGER

The Benguet mining district in the Philippine Islands is one of great scenic beauty and of much interest to the visiting engineer. To the average American these islands suggest a tropical and unhealthy region only and not many know of the existence and beauty of the mountain sections. The province of Benguet is in the northern portion of Luzon and is reached from Manila by railroad over the low tropical coastal plane to Camp One, a distance of about 150 miles, from whence by auto stage about 30 miles up the renowned Benguet road, into the mountains, to Baguio, the principal town, and distributing point of the province. It is also the summer capital of the Philippine Government and a social and health resort. This region has long been a place for the foreign residents of the islands to resort to

all mining needs for timber. The rainy season is from June to October. At this time violent storms, called *baguios*, occur with terrific winds and rain; as high as 40 in. of rain in 24 hours has been recorded. The destructive effect of these *baguios* has been enormous; in a hilly country these deluges of rain rapidly swell the creeks to raging torrents and with the debris from the frequent landslides furnishes a power which obliterates everything in its path. It has been difficult to find small water-power installations that would not wash out, but there are several large streams in the district where electrical power could be safely developed, and would be of great benefit to the mining and other interests of the district.

The natives of this region are the Igorrotes whose curious customs are of much interest to the new-comer. They are a tough wiry mountain people of darker skin and larger build than the natives of the lowlands, and of cleaner and more wholesome appearance. Numerous small villages, called *barrios*, are frequent throughout the country, having perhaps 50 to 100 inhabitants. Formerly there was considerable rivalry between neighboring *barrios*, and if one increased in population over another, danger would be felt by the smaller and attacks would be made, the victims being decapitated and the heads displayed as a sign of power; hence the derivation of the term 'head hunters' given these people. Their food consists mainly of rice, fish, and *cammotes*, the native sweet potato. Dog meat is considered a delicacy. The weekly dog market at Baguio is an interesting sight. Dogs of mongrel type are brought from the lowland towns to be sold, bringing ₱0.50.\* Curiously enough, they are not killed until they have been starved. They are allowed to run around the hills until they are thin and emaciated, when the meat is considered choicest.

The Igorrote men usually go about in scant clothing. A turban effect for a hat and a gee-string is about the extent of their dress. The women generally have a brightly colored blanket wrapped around them in a rather picturesque manner. They all go barefooted and their feet are much broadened and calloused. They can travel over the roughest rock slides without discomfort while packing heavy loads. Both women and men are great packers and are met everywhere in the country carrying loads, often weighing as much as themselves, by aid of a tump-line over the forehead. When strangers are met as they journey along, they chant and twang a native stringed bow. This is supposed to drive away the evil influence. Withal they are a peaceful people and are largely used as laborers in the mines and for packing, road work, wood chopping, and other rough work. There are a number of lowland Filipinos in the district who are more largely used for underground mining work. There are also a small number of Japanese and Chinese who make their living as carpenters, blacksmiths, and small merchants. The wage scale is about as follows:

Igorrote laborers, per day.....	₱0.80 to ₱1.20
Igorrote and Filipino miners.....	1.20 " 1.60
Native <i>capitasas</i> .....	2.00 " 2.50
Japanese carpenters and blacksmiths.....	2.00 " 3.00

They are fairly efficient workers if under proper supervision, which is most essential. They perhaps work to best advantage under a contract system. Supervision is accomplished by native shift bosses, who generally speak a little English. Experienced white foremen under a superintendent complete the organization. The cost is high, and in small mines may amount to as much as the actual labor itself. Mining has been conducted in the Benguet province for many years, dating back to old Spanish times. The old workings and the crude stone mortars for grinding the ore are in frequent evidence today and indicate prospecting and treatment of the rich streaks only. Nothing extensive

MAP OF LUZON.

for relief from the tropical heat of the lowlands. On American occupation in 1898 a great many improvements were made in the building up of the town of Baguio and the construction of the Benguet road, which made the district easily accessible.

Baguio was laid out by a well known landscape artist and is beautifully situated. There are numerous substantial government buildings, two good hotels, and a number of mercantile concerns; the elevation is about 5000 ft. above sea-level and the nights are always cool; the population varies from 300 to 1000 people, depending on the season of the year. The country surrounding is of great natural beauty and resembles the foothills of the Sierras together with the White Mountain region of New England. The topography of the country is one of sharp relief, with steep hills, deep gulches, and sharp ridges that rise 200 to 1000 ft. above the adjoining ravines; landslides have been frequent and in many places great bare spots testify to the large movement of earth and rock. From a physical point of view the country is in its early stages of dissection, but is being rapidly eroded. Pine forests abound in this section and serve

\*The Philippine peso has a value of \$0.50.

was accomplished until American occupation in 1898. Since then a number of mining companies have been prompted to exploit this mining field, several millions of dollars having been spent. There are seven mills in the district, but the Headwaters is the only one equipped to make any close saving. The prominent mines are the Benguet Consolidated, Headwaters, Major, Kelly, Muyot, Bua, and the Cammote. As yet no mine in the district is in anything like a stable paying basis, and it is widely conceded that lack of experienced men in charge and wasteful misman-

agement has been the cause of the general failure of the district to make good up to date. It is a common thing to attribute mining failures to mismanagement, and while this has undoubtedly much to do with the non-success of some of the Benguet mines, still there are many conditions, both physical and operating, that are difficult or impossible to overcome. The deposits are as a rule low grade with average range of \$3 to \$8 for workable ore. The rich ore is irregularly distributed and there is much of the vein matter that will not pay to work. The present workings are mostly in the oxidized zone and the ground is soft and heavy, requiring careful and expensive timbering to hold in the rainy seasons. In some cases there are metallurgical difficulties in that a considerable portion of the gold is

associated with sulphides which are difficult to treat by cyanidation, and the concentrates are not high grade enough to stand the treatment charges and freight to San Francisco. Most of the ore is clayey and slimes excessively. Agitation is necessary. Generally not over 30% of the gold can be saved by amalgamation. The destruction of several mills and other improvements by *baguios* has been unfortunate and a big setback to several of the mines. As in other mining areas a great deal of money has been wasted in useless work and mills have been built before

A SCENE IN THE LOWLANDS.

IGORROTE BOYS.

development justified. The Philippine mining law requires annual work to be done on each claim separately, and this is quite a disadvantage to small operators, as annual work is often done to best advantage at one place for the benefit of a group of claims.

Generally speaking, the mineralization has been extensive over this area, and it would seem that in this as in other districts, some good mines should be developed. The Benguet Consolidated is generally believed to be the most promising property in the district, having a large lead and with a considerable tonnage of ore blocked. Misfortunes have occurred to this enterprise in the total loss of their plant through destruction by *baguios*, but the outlook is now good.

development justified. The Philippine mining law requires annual work to be done on each claim separately, and this is quite a disadvantage to small operators, as annual work is often done to best advantage at one place for the benefit of a group of claims.

## Geological Survey Building

\*The offices of the United States Geological Survey have become wholly inadequate and unadapted to its needs. Since 1884, when the Survey was first quartered in the Hooe building, at 1330 F street, the effort has been frequently made to provide for the growth of the organization by adding extensions to the building, but every increase in floor space has been made at the expense of proper lighting of the older portions of the building, so that its fitness for the survey's use has been steadily impaired, and the resultant conditions constitute an actual detriment to health and a menace to life and property, as well as an obstacle to efficiency.

The present quarters of the survey can be described without exaggeration as in large part comparable to a sweatshop. Treatment of wage earners that would excite severe criticism if a corporation were the offender, is tolerated in the case of these employees of the Federal Government. In one division statistical clerks have each on an average only 73 sq. ft. of floor space. In another branch the floor space allotted to each person is 67½ sq. ft., and in still another, in which the workers are for the most part

scientists, the average space per man is 102 sq. ft. The figures given do not measure the actual working space available, for not only must desks and chairs be provided, but also bookcases, large file cases, and in many rooms drafting tables.

### LACK OF FRESH AIR AND LIGHT

If instead of floor space the cubic capacity of the rooms occupied is measured, it is found that the average volume of air per person is about 652 cu. ft., again without allowance for the considerable space occupied by furniture and therefore not available for air. Certain more or less definite standard minimum requirements for the cubic contents have come into use for various classes of public buildings, these requirements being based on the customary allowances for fresh air. Thus public libraries are planned with not less than 2400 cu. ft., hospitals with a minimum of 1440 cu. ft., and barracks with not less than 720 cu. ft. of space per occupant. The average cubic space available for each person occupying the survey rooms is therefore below even the minimum allowed in barracks and only a fraction of that allowed in other buildings. When ventilation is taken into account the showing is even worse, for more than half the windows of certain rooms open into interior wells and the rest into alleys.

In the matter of lighting the conditions are no more fav-

\*From the Thirty-third Annual Report of the Director.

orable. In one of the divisions already cited the average window space per clerk is two-fifths of a small window, and here again many of the windows open into interior wells, so that in most of the rooms artificial light is necessary on dark days and even for several hours on clear days in winter. The generally crowded condition has compelled the occupancy of several rooms in which artificial light must be used practically all the time. In one of the scientific sections the largest floor space assigned to one man—162 sq. ft.—is in a room where the light is so poor that artificial illumination is needed most of the time, and the strain on the occupant's eyes is so great that rotation in assignment to this office is practised in order that permanent injury to any one employee may be avoided if possible.

While permanent or temporary injury to the eyesight of some of the geologists and draftsmen can be definitely traced to the poor lighting of the rooms in which they have been forced to work, it is more difficult to trace the results of insufficient ventilation. That the unhygienic conditions prevailing in the building occupied by the survey must necessarily lower the tone of the health of its employees is apparent. The customary standards for ventilation provide for a minimum of 1000 to 3000 cu. ft. of fresh air per hour per occupant.

The results of this violation of practical hygiene would be more widespread and more apparent were it not for the fact that a considerable number of the members of the survey are field men, whose work during the summer is performed in the open air where they have opportunity to recuperate each year. This open-air work may protect certain members of the force from lung disease and from defective vision, but it does not make the congested conditions seem any more tolerable to a geologist or topographer who has been assigned 1000 square miles for five months of field service and is obliged to work the remaining seven months of the year with an allowance of 100 sq. ft. of floor space.

#### ROOMS TOO HOT FOR OCCUPANCY

The top floor in the main building of the survey and the loft in the annex become so hot in the summer that at times it is impossible for the employees occupying these floors to perform their duties. In the loft of the annex, an old building in an alley, the summer temperature runs as high as 110° F., and neither the employees nor the solutions and emulsions used in the photographic laboratory there can be depended on for high-grade results under these conditions.

#### THE FIRE RISK

A menace second only to the existing danger in health is the risk to public records. Estimates have been made at various times of the money value of the records necessarily stored in building. The latest inventory shows a present value of \$4,840,000, and this value represents largely the amount that would necessarily be expended in duplicating the unpublished material and in replacing the large stock of map plates which could be re-engraved from published maps. Moreover, there is a sense in which the loss in official records can not be estimated in dollars. The detailed stream-gauging records for 20 years could not be replaced except by another 20 years of observations, and similarly, unpublished geologic data contained in notebooks and plats and represented by the working collections of specimens could hardly be replaced, except in an equal length of time. The land-classification work is now proving how invaluable are these unpublished data, and a destructive fire in the wing of the building occupied by the land-classification board would destroy records whose loss would long delay the issuing of land patents throughout the public-land states.

The library is a collection of geologic literature that in degree of completeness can not be duplicated elsewhere in this country, if indeed in the world. This library therefore has a value which can not be easily estimated, since, if destroyed, it could not be wholly replaced, and such portion as is replaced could be duplicated only at great expense

of time and expenditure of public money.

It is believed that every safeguard against fire that is possible through an efficient watch service and the careful distribution of fire extinguishers has now been provided, but the fact remains that although the building is constructed of iron and brick it is honeycombed with light wooden partitions, which present some two acres of surface that could be easily ignited. The exterior fire risks should also be considered, inasmuch as all the buildings in the block, except two, present even greater fire risks than the building occupied by the survey. During the last nine years there have been four fires in the survey building.

#### IMPAIRMENT OF EFFICIENCY

Maximum efficiency is impossible with such congestion and the attendant inadequate ventilation and lighting and with the impossibility of systematically arranging the offices and working collections; and the dirt and noise consequent upon position at the very business centre of Washington present further obstacles to economic administration. The whole situation not only results in less efficient use and hence in actual waste of government money, but also on that account creates a feeling of dissatisfaction and discouragement among the highest class of scientists and other members of the survey, who wish to make the largest and best contribution possible to the public service. Tests have shown that light suitable for clerical or technical-clerical work fails at approximately a distance of 15 ft. from the window line, yet 12½% of the floor space occupied in the main building is more than 15 ft. from the windows, and this computation is based on the assumption that the windows in the light wells are as effective for lighting as are those on the exterior walls. If a lighting factor of 50% is assumed for the well windows on the lower floors, the space unsuited for clerical work in the building is found to be 33.8 per cent. The crowding of the survey building precludes a systematic arrangement of offices and of working material, including specimens, notes, and maps, that should be close at hand for repeated reference. This separation of men and materials that ought to be closely correlated is seriously retarding the scientific work.

In addition to the prevalent noises of exterior origin, which constitute a great drawback to intellectual work, there are interior noises, inevitable upon the crowded condition of the building—noises that are amplified or intensified by numerous wooden partitions, which constitute excellent sounding boards. The common arrangement of having a stenographer share a room occupied by a high-salaried man engaged in scientific investigations is not to be commended for its efficiency, yet the present congestion is so great that relatively few of the geologists are ever free from the distracting noise of the typewriter. In the computing sections of another of the scientific branches six or seven hydraulic engineers are crowded into a single room, together with an adding machine or two. Inasmuch as hydraulic computations require constant attention and freedom from diverting noises, it is plain that larger quarters and some degree of isolation would facilitate the work. A careful estimate places the possible increase in efficiency at 30%, which would represent an annual gain of several thousand dollars in this one section alone.

#### INCREASE OF EFFICIENCY POSSIBLE UNDER BETTER CONDITIONS

Several other estimates have been made by the administrative officers of the survey of the increased degree of efficiency that could be attained by changing the quarters for the various classes of employees from indifferent or worse to suitable accommodations. The estimated increase ranges from 15 to 30 and even to 50 per cent. The present housing of this bureau is unworthy of the nation.

The practical side of this feature is the increased inducement that suitable quarters would afford in retaining in the government service men of the highest professional talent. To retain in the government service the best men is by far the largest administrative problem of the Director of the United States Geological Survey.

# Mining Methods in the Waihi Mine

By JAS. L. GILMOUR AND W. H. JOHNSTON

"The ore is extracted from the mine by several systems, according to the conditions and nature of the orebodies and the enclosing country. The systems may be classified as follows:

(1.) Driving and widening out of levels. (2.) Ordinary flat-back or overhand stoping and filling. (3.) Overhand stoping with square-sets and filling. (4.) Shrinkage stoping and filling. (5.) Taking out of arches. (6.) Surface work.

## DRIVING AND WIDENING OUT OF LEVELS

The levels in the lower section of the mine are at 150-ft. intervals. In the upper and older workings the distance varied from 50 to 110 ft. Preparatory to mining, a care-

CROSS-SECTION OF WORKINGS.

ful scrutiny and comparison is made of the mine maps, the position of the ore is noted, the character of the lode and the enclosing walls considered, and the system of stoping determined. In most cases the development level is widened out to the full width of the ore and to a height of 10 ft., with machine drills. The tram-line is re-laid, generally with heavy rails where traffic is likely to be constant, and is straightened as much as the course of the lode will permit. Timbering with ordinary sets then follows. The sets are made up of three pieces of timber, usually split rims, roughly squared or sawed, and varying in size from 12 to 15 inches. The legs are hitched 6 in. into the ground, spaced not less than 3 ft. 8 in. in the clear, according to the size of the timber, the sides covered with slabs 5 ft. long of 2 by 9-in., spaced 6 in. apart, and the cap closely boarded up. An illustration is shown in Fig. 1.

To provide room for sinking winzes clear of the tram-line, two caps 6 ft. in the clear are put in at intervals of 80 ft., with a 5-ft. cap on each side of them. The open space between the outside of the sets and the standing ground is filled with waste, either from dead-work cross-cuts in the vicinity or dumped through winzes from the level above and packed behind the sets up to the top of the caps. Chutes are generally spaced 18 ft. along the level in

ordinary stoping blocks, and 9 ft. apart in shrinkage blocks. These chutes are made of 2 by 9-in. planks, with two 2 by 9-in. stoping boards, the angle of the bottom being 40° from the horizontal. The mouth of each chute and the tram-line are placed as close as possible to one side of the drift to permit of horse traffic, if subsequently desired.

Although timbering preparatory to stoping is usually done with ordinary sets, there are exceptions where stulls are

SECTION SHOWING POSITION OF OREBODIES.

used in their place. The stulls, 14 to 18 in. diam., are used up to 16 ft. in length, and are spaced 3 ft. 8 in. (not less) apart, at an angle of 40° from the horizontal, and closely covered with slabs. It has been found, however, that in the round timber used in this system decay sets up much more quickly, so the system has not been used in the later workings. An illustration of stull timbering is given in Fig. 2. The A drift or saddleback set has also been used on a lode 18 ft. wide, the legs being hitched into the rock, leaving the lode matter clear of timber. The advantages of both these last methods chiefly is that the arch of ore

FIG. 1. ORDINARY SET.

under foot can be taken right out without disturbing the timbering and without temporary support; but, in spite of this advantage, the ordinary set is in general use, being more reliable and more lasting.

## ORDINARY OVERHEAD STOPPING AND FILLING

Most of the ore from the mine is broken by this method. Winzes are sunk through the block of ore to be worked

\*From the *Proceedings of the Australasian Institute of Mining Engineers.*

from the level above, 80 ft. apart, either during the progress of development or before stoping is begun. The first, or leading stope is started at each winze on the top of the level sets, and the filling that has been previously packed in beside the timbers, and the full width of the lode or section of the lode is broken out each way horizontally for a height of 8 ft. and a length of 40 ft., the broken ore being rilled and shoveled into chutes and trammed to the shafts. Under this system, stoping widths of 150 ft. are common on the Martha lode, and on the Edward a width of 80 ft. has been taken out without any support to the

FIG. 2. TIMBERING IN STOPE UP TO 10 FEET.

roof. In stopes of these dimensions, however, it is necessary to have two parallel drifts in the level to facilitate the handling of the quantity of ore.

After cutting a stope, the chutes are timbered up 8 ft. high, with rough split logs or cribbing 8 in. and 9 in. diam. built on top of one another and cut 4 in. deep and 8 in. long at the ends, forming a pass 4 ft. square inside. Filling material is then dumped into the winzes at the level above, safety precautions being first taken by setting in 14-lb. rails 12 in. apart across the winze 3 ft. below the level, and placing movable horizontal bars across the drift 4 ft. from the floor on each side of the winze, besides providing strong 9 by 3-in. foot-planks for crossing.

The filling is trimmed along the stope from the bottom of each winze 40 ft. each way to within 2 ft. of the roof of the stope. Ladder-ways, 3 ft. square inside, are cribbed up about 80 ft. apart in the filling, and fitted with ladders built of 2 by 4-in. kauri timber 12 ft. long, with ¾-in. iron rungs spaced 12-in. centres, dogged and spiked to the cribbing. Slabs are then laid on the top of the new material, and the block is ready for the second stope. Stope after stope is broken out and filled in this way up to what is considered a safe thickness of arch for the temporary support of the level overhead. The thickness of this block varies with the width of the stope and the nature of the lode and surrounding walls, and may run from 7 to 24 ft. In working the stopes it has been found necessary to keep the chutes constantly full of quartz, and strict attention is now given to this. Much delay and expense was formerly incurred through the wearing-out of chutes caused by running them down; but with passes kept reasonably full at all times it is found that the timbers will last till the block is worked out.

In this method of stoping no timber is used, as a rule, to support the roof. The roof is kept well arched, and any loose rock barred or worked down. Machine drills are not used in this system, except, perhaps, in the leading stope, owing to the soft nature of the surface material of which the filling is chiefly composed and the necessity of keeping this material as dry as possible. In wide stopes holes are usually drilled 6 and 7 ft. deep and 7 or 8 ft. above the bottom of the stope. These holes are widened out in the bottom by firing a small charge first, and then the full charge is inserted and fired, generally bringing down large quantities of rock. Stoping by this method is let on contract, the number of tons let in one contract varying from 5000 to 50,000; and a system of weighing, tallying, and checking, determines the quantities. Excepting what is

obtained from dead-work underground, the filling material is broken on the surface. The decomposed country rock encasing the lodes is found to make the best filling material, being easily broken, easily handled in damp weather, and packing tightly in a short time. To obtain this material, adits 6 ft. wide and 6½ ft. high are driven into the hill, usually parallel with the course of the lode outcrops, where such occur, and, when far enough advanced to command material overhead, raises are put up to the surface. The bottoms of these are fitted with horizontal doors placed in the centre of the roof of the adit and the material is filled into cars of 42-cu. ft. capacity, and hauled, generally by horses, to the various filling shafts. The filling is at first broken out from surface downward to the back of the level in the shape of an inverted cone; but this is subsequently opened out into an open cut with the floor on the roof of the adit. The cuts are then worked in open faces in benches from 7 to 10 ft. high, which are carried up on a slope of about 40° in a semicircle round the loading chute to heights varying from 50 to 100 ft. This method, besides being economical, is best suited to the conditions of heavy rainfall in the locality, amounting to 101.8 in. per year (average for the past four years), as all water is easily drained off through the adits to a safe outlet. Holes from 6 to 10 ft. in depth are easily 'jumped' in this rock with 1-in. steel, and strong steel boring augurs, worked by hand, are extremely effective in the bottom of the cuts, in holes at an angle of 40 or 45° above the horizontal. Special filling chutes or small shafts are sunk, usually on an underlie, in the solid rock for the passage of this material from the surface to the different levels in the mine, and the upper portions of the shafts, through the wet strata, are generally fitted with 12-in. steel pipes, through which the filling is sent down to the drier zones. Some of these chutes are now in constant use, delivering material at depths varying from 500 to 850 feet.

At the different levels where filling has to be trammed to the winzes in the stoping blocks, large hoppers are constructed with three gates on each side of the chute, and enough material is stored underground to provide work for a day if it is too wet for surface work or if repairs have to be done to the chutes. The hoppers are so arranged that the material can be caught at any particular level, and at the same time sufficient run through for the requirements of any lower level.

Filling-in material is broken and delivered to the passes by contract, at so much per cubic yard, and quantities are determined by measurement on the surface, measurements being taken at the usual monthly intervals. Investigations were made of the behavior of this material in transit, to find if possible a simpler method of tallying at the delivery levels, but the variations of volume were found to be so uncertain, and with such wide limits, that the system of measurement in place was adhered to. Extreme and uncertain differences in volume were found when the material was first broken into cars, when it was dumped into the filling chutes, when it was filled at the receiving level, and finally when it was dumped into the stope, by which time it was generally in a finely pulverized state. The differences were further aggravated by the presence or absence of moisture, depending upon the weather conditions. Owing to surface configuration, the presence of old drifts, cuts, trenches, and dumps, and the necessity of taking material where it can be easiest obtained at the time, without regard to systematic work, the accurate measurement of these cuts is a task of some difficulty. By a detailed system of cross and longitudinal sections, or a combination of both, the outlines of the figures broken out each month are deduced and contents found by the method most applicable to the shape of each body.

#### OVERHAND STOPING WITH SQUARE SETS, AND FILLING

This system is in use where the roof will not stand without support, or where a band of loose rubbly quartz or old filling exists on the side of the stoping block. The sets are made of rough round timber, about 12 in. diam., placed 4 ft. apart along the course of the stope and 5 ft.

apart across its width, with a height of 7 ft. As each stope proceeds the timbers are put in close up to the work, and wedged up to the roof, and, as work advances, the portion taken out is filled up close with filling from the surface. The following stope is worked off the filling, the timbers being placed on top of the sets in the lower stope, and this system is carried up to the floor of the level above, the whole of the ore being taken out. In certain cases, where a large portion of the lode consists of loose rubbly ore, the winzes, originally sunk in the reef, have fretted away to large dimensions, and eventually have had to be filled with waste, thus cutting off the supply of filling material.

This difficulty has been overcome by sinking new winzes for filling purposes about 5 ft. away from the lode in the foot-wall, from foot-wall gangways, and starting each stope from one of the winzes. Chutes for ore, 3 by 4 ft., are brought up inside the stoping sets on the inclination of the lode, the struts being removed, and the cribbing taking their places, as the sets are passed. These stopes are taken

allowed between the roof and the broken quartz while work is in progress. No shoveling of the ore is required, and the material is broken out for the full width of the lode or stoping section up to a safe arch for the level above.

This stoping is let by contract at a price per ton for ore delivered at the shaft and a price per ton of ore broken in the stope. The ore delivered to the shaft is fixed by tally, and the broken quartz in the stope is determined each month by careful measurement. As in the case of surface work, this material is measured and leveled in a system of cross and longitudinal sections. Considerable variations may be found in the individual measurements of this work, caused by filling material temporarily hanging up when being drawn off. It is not unusual for a whole body of this material to sink suddenly 2 or 3 ft., although tramming has been going on for some time without any movement.

The price for tramming out the ore temporarily left in the stope for filling is held back until emptying the stope is begun, when it is paid as tramming proceeds. When

FIG. 3. SHRINKAGE STOPING.

out and by contract at a price per ton, delivered at the shaft.

#### SHRINKAGE STOPING AND FILLING

This system has been adopted during the last four years in places where the reef walls are sound and unlikely to fall away. Seven or eight blocks are now constantly at work by this method, and an endeavor is made to regulate the procedure so that two blocks will have completed ore-breaking, and in process of emptying, while the others proceed with breaking. The preparations for this system are the same as described in the driving and widening out of levels, with the exception that the filling packed behind the sets must be sloped up from the caps to the sides of the stope on an angle as steep as possible, to allow the broken quartz to run down to the chutes, and the chutes must be 9 ft. apart. Only one winze usually is sunk through the centre of a block, from which the stopes are started, and a ladder-way 4 by 4 ft. is cribbed up at each end, through which an air current is led. The length of blocks taken out by this method varies from 150 to 300 ft., and widths up to 50 ft. have been taken. The ore is broken down with machine drills, spalled to small size, and a portion drawn off through the chutes as work proceeds, leaving sufficient in the stope to enable men to work without staging or timber of any kind. In practice it is found that 40% of the broken ore has to be drawn off to leave convenient room for the working of the stope. It is important that the ore-filling should constantly be kept close up to the roof, and in no case is a space of more than 8 ft.

emptying, the ore is drawn off from one end first, and filling from the surface is dumped into the space down winzes sunk through the level arch. As the ore is drawn away in front waste filling is dumped in till the whole block is filled up tight to the arch above. This is illustrated in Fig. 3.

It is sometimes found convenient in blocks of small length, to draw off all the ore first before filling begins, and then quickly fill up the whole space. It is usually found, in drawing off, that some rock scales off from the hanging wall, and follows down on top of the ore; this is finally left in the stope for filling. Under favorable conditions, this system of stoping has been found to be the most economical method yet practised, there being no cost for shoveling ore, no timber used, no cribbing of chutes, and less trimming of filling material.

#### TAKING OUT OF ARCHES

In dealing with the arches of ore usually left to support the levels, a start is made by placing strong stringers horizontally along the bottom of the level on each side of the track, close up against the sets. These are 15 to 20 ft. long, or long enough to reach between three or four sets of timber. After they are in position, a 1½-in. hole is bored into each leg, flush with the upper side, and a stout iron bolt is driven into each, with the projecting ends tight on the top of the stringers. This bolt keeps up the leg while the ground is cut away. On top of the bolt and stringer a piece of timber is wedged up under the cap to take the full weight of the set, and spreaders are driven between the legs

to prevent side movement. An illustration of this is given in Fig. 4. The arch is then ready for breaking out for the number of sets supported in this way, and the ore is removed from under the first set, down to the old stope filling. In dealing with lodes up to 15 ft. wide, single stulls are used with advantage for permanent support, being placed under the set just laid bare and firmly hitched into the foot-wall. On this the set is secured, and the booms blocked up from each one as the work proceeds.

After the ground has been taken out for three or four sets the open space is immediately filled in with hard rock, if procurable, and the stringers are moved on another length. It will be readily seen that this method is safe, as one end of the stringers is always resting on the solid arch and the other is packed up from the stull pieces which take the place of the arch. In dealing with lodes up to 20 ft. wide the same system is adopted in securing the level timbers; but,

FIG. 4. TAKING OUT ARCHES IN STOPES UP TO 15 FEET.

as the length of stulls for this width would be about 28 ft., saddleback sets are used in place of stulls. This set consists of two legs hitched into the walls with a cap piece between, as shown in Fig. 5.

In cases where the walls are not good, sill pieces are laid down on the top of the old filling in the stope below, and square sets built on these, the level timbers and stringers being taken upon the square sets. This is illustrated in Fig. 6. When the old level timbers are crushed or decayed, a foot-wall gangway is driven in the country rock about 6 ft. from the lode and parallel with it, but about 10 or 15 ft. below the floor of the original level. An ore-chute is constructed from the gangway to the level below, and the arch is attacked from the gangway and timbered with square sets. This method is the safest in treacherous ground, and recovers all the ore standing.

#### SURFACE WORK

The filling material required underground for packing stopes is derived chiefly, as previously described, from open cuts which are directed, where possible, along the lines of the old outcrops. In the course of excavating large quantities of waste rock, a considerable amount of ore left in the old workings is laid bare, this is quarried out and trammed by horses to the surface hoppers.

#### HOISTING

The ore is raised to the surface through three shafts—No. 2, 4, and 6. No. 4 shaft is equipped with cages specially built for expeditiously handling timber in long lengths, rails, and pipes. One car only is carried per trip, but the cages are arranged for carrying 12 men. No. 2 shaft is now being re-equipped, and will be fitted with single-decked cages, with two cars per cage, placed side by side. The No. 6 is the main hoisting shaft, and is equipped with 3-ton self-dumping skips. A short description of the plant follows:

FIG. 5. TAKING OUT ARCHES IN STOPES 15 TO 20 FEET.

The hoisting engine is a two-cylinder high-pressure engine, having 30-in. cylinders, 6-ft. stroke, and is fitted with double-beat drop valves and an automatic cut-off gear. Steam brakes and a steam reversing engine are also provided. The engine is direct-acting, and has cylinder drums 12 ft. diam., the rope used being 4 in. circumference. The plant is supplied with steam power from two multitubular boilers at a pressure of 100 lb. per square inch.

The head-frame is 75 ft. high from the collar of the shaft

FIG. 6. TAKING OUT ARCHES IN WIDE STOPES, SQUARE SETS.

to the centre of the pulleys, and is built of kauri timber. The pulleys are 12½ ft. diam., and the shafts for the same run in pedestals fitted with ring lubrication. The tipping gear is built into the legs at a height of about 50 ft. from the collar of the shaft. The ore is discharged down chutes lined with rails and grizzly bars into a main hopper capable of holding about 3500 tons. A double-line track runs beneath this hopper, on which the mill cars are filled.

At No. 7 level, 700 ft. from the collar of the shaft, a hopper bin, capable of holding about 350 tons of ore, has been excavated. Beneath this a smaller chamber for accommodating the auxiliary bins has been cut, as illustrated in Fig. 7. Two auxiliary bins are provided—one for each hoisting compartment, made of cast iron lined with rails and steel plates, and the capacity of each is one skipful. The discharge doors of the main bins deliver into them. The doors of the auxiliaries are vertical, and made of steel plate working in guides. They are raised by means of hydraulic

rams receiving water from one of the upper levels at a pressure of about 200 lb. per square inch. They close by their own weight, and are cushioned by throttling the water in the discharge pipe from the cylinder. A steel tumbler is bolted to the shaft sets below the auxiliary bin, and leads the ore from the lip into the skip; the skip coming up closes this tumbler, being assisted in so doing by a balance weight on the tumbler shaft, and the skip-tender has to reopen it by means of a wire rope and lever. This arrangement ensures that the shaft is always clear, with no possibility of the skip striking any of the gear.

FIG. 7. CHAMBER FOR UNDERGROUND BIN.

The advantage of this is the saving in time effected in loading the skips, as the auxiliary bins are being filled while the skip is traveling in the shaft. They are emptied by fully opening the door, and there is no danger of spilling, as the capacity of the hopper is exactly one skipful, as illustrated in Fig. 8.

The hoisting compartments in the shaft are, however, too narrow to take full advantage of this arrangement. The inside widths of the skips being only 2 ft. 3 in., it follows that the tumbler and auxiliary hopper widths are restricted, necessitating poking when extra large pieces come through. Notwithstanding this disadvantage, the loading is fairly efficient, and 44 skip-loads (132 tons)

have been raised and dumped in one hour from this level, a total height of about 800 ft. This whole loading equipment was constructed in the company's workshop.

At the 1000-ft. level chambers have been cut on each side of the shaft, and arrangements made so that the skip is filled from both sides at the same time. On the south side of the shaft there are cast-iron chutes, with tumblers

FIG. 8. AUXILIARY BIN AND GATES.

attached, into which the cars are dumped, the ore going direct into the skip. This takes the ore from the 1000-ft. level on the Martha lode. Owing to water difficulties, a bin cannot be made below this level until the 1150-ft. level has drained off the excess of water. On the north side of the shaft there is an ore-bin, which extends from the 1000-ft. level up to the 850-ft. level. It is about 8 by 10 ft. in area, and has 12 ft. of solid ground between it and the shaft, holding about 450 tons. Owing to the skips being 2 in. narrower on the north side of the shaft than the south, the auxiliary bins referred to at No. 7 level were not attempted at this level, the ore being filled direct from the large bins.

## Mining Laws of Peru

Peru's mining laws are practical and fairly enforced. They provide, among other things, that the owner of the soil has title to slate, sandstone, building stone generally, gypsum, sand, potters' earth, earth containing magnesium and aluminum, peat, and phosphates. When these are found on land of the state the Government may work them for itself or issue concessions. Guano beds, salt deposits, and brine wells are state property. Nitrates, borates, and alkaline salt deposits are subject to special laws. All other deposits of mineralized or fossilized substances can be acquired by petition and denouncement, as also water, slag, or tailing. Mining property, once obtained, is irrevocable so long as the mining tax is paid and is as perpetual as common property.

The unit of the mining claim is the *pertenencia* of 100 by 200 metres, being 2 hectares, of 4.94 acres. In placers, coal, and petroleum deposits the *pertenencia* is 200 by 200 metres, or 9.88 acres. A concession may embrace up to 60 *pertenencias*. Prospecting and exploration concessions are granted ranging in size from 60 to 600 *pertenencias*, and

one person or company may obtain several concessions, which are granted for one year, but may be extended for another.

A tax of 49c. per hectare per year is paid on prospecting grants. Mining concessions pay \$14.60 per *pertenencia* per year, payable semi-annually. Formerly non-payment during three half-years canceled the title, but arrears could be paid before that time, with 50% fine for that part half a year overdue and 100% for that one year overdue. By a law which became effective on November 3, 1911, however, unpaid mining taxes are subject to an additional penalty tax of 20 or 40%, or both, according to the length of time they are overdue. If three half-years, or 18 months, should elapse before the payment of these taxes the mine becomes an abandoned one, a list of such abandoned mines being required to be published in February and August each year. Peruvians and foreigners alike may own mining property in Peru, except certain specified officials and employees of mine owners. The right exists of expropriation of surface area for necessary buildings, shafts, etc.—From a *Consular Report*.

TIN has been discovered in the province of Alacania, Chile.

## The Evolution of a Bullion Refinery—II

By HAROLD FRENCH

(Continued from Page 755)

The Philadelphia plant proved so satisfactory that George E. Roberts, Director of the Mint, detailed R. L. Whitehead to construct a combination Moebius and Wohlwill plant at the Denver mint. This was completed in 1905 and embodied many important improvements. The floors, part of the walls, and most of the interior furnishing were of acid-proof soapstone. Two motor generator sets supplied a maximum current of 700 amperes at 15 volts. The Wohlwill process was operated in a series of porcelain cells, 18 in. long, 13½ in. wide, and 1 ft. deep. As a new departure, gold chloride was directly generated by the aid of the electric current, instead of by heating gold in aqua regia and boiling off the nitric acid from the solution. It is essential that a considerable stock of auric chloride solution be kept on hand in this process to replenish the gold in the electrolyte according to the rate of its decomposition by the current. Glass rods, tipped with propeller blades, and immersed in the solutions, agitated the electrolyte, facilitating the deposition of the gold. These were run by a small motor. The capacity of the Denver refinery averaged for a considerable period 5000 oz. fine gold and 13,000 oz. fine silver per day.

Some of the many improvements in the silver-refining system were the use of gold hangers which, being insoluble in the nitric acid electrolyte, almost completely submerged the anodes in the solution and gave a better contact. A higher percentage of gold was permissible in the silver anodes, remaining as a core, which was lifted out of the solution before it disintegrated. The cathodes were periodically stripped and the sheets returned to the cells. The parting of this doré bullion was effected in large earthenware tanks of the Bertuch pattern, 47 in. long, 26 in. wide, and 22 in. deep, through which the electrolyte circulated *en cascade*. A monteju forced the solution from a sump-tank to a distributing jar, from which it flowed from cell to cell. The gold cathodes were removed when 1 in. thick, washed, dried, and melted into fine bars, containing 1 to 5 parts of alloy in 10,000. The slime, consisting of chloride of silver and gold scrap, was boiled with  $\text{H}_2\text{SO}_4$ , with the formation of  $\text{Ag}_2\text{SO}_4$  and the evolution of  $\text{HCl}$ . The slime from the silver cells was digested with  $\text{HNO}_3$ , leaving the gold residue in a form suitable, after melting, for electrolyzing in the Wohlwill process. For a number of years the output of the Denver refinery has averaged nearly \$30,000,000 per year in fine gold and silver.

### REMODELING THE SAN FRANCISCO REFINERY

At the close of the fiscal year 1906-7, the sulphuric acid refinery at the San Francisco mint was dismantled and a complete new electrolytic plant was constructed by R. L. Whitehead. Work began March 1, 1908. The constructing engineer, at this plant, improved upon his work at Denver in many ways. Greater space permitted the placing of a much larger plant, with many extra conveniences for which there is no room in the Denver mint. The generator room contains two motor-generator sets capable of producing 1000 amperes at 15 volts. A third set supplied a current of 500 amperes at 25 volts to the cell where gold chloride is generated, while a fourth furnishes 200 amperes at 6 volts to a series of copper tanks. A massive six-panel switchboard, built of Alberene, 8 ft. high and 15½ ft. long, was equipped with switches, circuit-breakers, voltmeters, watt-hour meters, and Bristol recording ammeters, affording a check on the efficiency of the gold and silver cells and their operatives. The preparation of gold chloride was conducted in much the manner as at Denver. Anodes of gold, averaging 995 fine, were decomposed in a solution of half-strength hydrochloric acid. Cathodes of much smaller size, hung in porous cups, received a current density as high as 250 amperes per square foot. Generally 500 amperes at

25 volts was passed through these cells, evolving quantities of hydrochloric acid, which was conveyed through a hood to the roof. After nearly two days electrolyzing, the gold chloride attained a strength of 450 to 500 gm. gold per litre, or about 30% gold by weight in solution. At this strength the gold chloride solution acquires a beautiful reddish-orange hue. In the sunlight it frequently shows a shimmering mass of finely divided gold and aurous chloride.

Porcelain cells, 28 in number, were arranged in two rows. The current from the main circuit was distributed through horizontal bus-bars to a series of gold strips bent over angular porcelain rods. From these gold hooks depend the anodes into the electrolyte, while sheets of fine gold, serving as cathodes, were suspended nearly an inch from the anode on similar porcelain rods, the upper end of the cathode being curved to cover the connecting strip of V-shaped gold. Care is taken to make the contacts as perfect as possible. The electrolyte was maintained at about 60 gm. gold per litre, with from 5 to nearly 10% of hydrochloric acid. Circulation was maintained by glass propellers, but objection was made against their use, on the ground that their action was too violent and hurled particles of silver chloride against the cathodes, thus lowering the fineness of the gold product. Mr. Whitehead had designed a porcelain pump with connections which would permit the circulation of the electrolyte from cell to cell. The equipment was ready for use on July 1, 1908, but was not installed for reasons given later.

A similar circulating arrangement caused the flow of electrolyte through the cells of the silver-refining system. Instead of the Moebius method, as employed at the other mints, the Thum process was applied to the separation of doré silver. Perforated stone-ware baskets were suspended in the electrolyte which nearly filled cells of Bertuch earthenware, 39½ in. long, 19½ in. wide, and 1 ft. deep. These receptacles held several anodes, composed of over 30% gold alloyed with over twice its weight of silver and nearly 10% base metal. The anodes were enclosed in 7-oz. duck, retaining the gold and insoluble base metal, but permitting the migrating ions of silver to pass through to the cathodes, beneath which were plates of graphite. The contacts were candle-like rods of silver welded to heavy slabs of silver. At intervals the deposited silver would be removed by rubber scoops. Frequent additions of nitric acid and silver nitrate were made to the electrolyte, according to assays which determined the deficiency of either constituent.

As the electrolyte became foul with base nitrates, it was drawn off and precipitated with copper suspended in wooden vats. In like manner, the chloride solutions, after a week's run, were removed in portable tanks and the gold precipitated with ferrous sulphate. Both spent electrolytes, after their gold and silver content had been removed, were transferred to a large tank where the copper and any of the platinum metals present were precipitated by scrap iron. This action was hastened by suspending the scrap iron in a copper basket and heating the solution with a steam injector. The cement copper has since been cast into anodes and electrolyzed in a solution of copper sulphate; the platinum metals collecting on the bottom of the tanks, where they were segregated and saved for future separation. The gold precipitate and the silver deposits and precipitate were washed in earthenware centrifugal rotors lined with duck, care being taken to keep the chloride washings apart from silver nitrate, and gold apart from silver, by washing the different substances in separate machines.

Slime from the gold cells was reduced, after washing in the centrifugal machine, by zinc and sulphuric acid. The precipitated silver, mixed with the gold fragments in the proportion of one of silver to two of gold, was blended with sufficient fine gold to bring the resultant alloy up to

over 900 fine. It was then reelectrolyzed in the gold cells. The treatment of slime offered a fruitful field for research, as the methods employed here and at the older refineries were far from satisfactory. In the East it was customary to boil the slime first with  $\text{HNO}_3$  and then with  $\text{H}_2\text{SO}_4$  to extract the silver.

Another room of the new San Francisco refinery was equipped with a water-cooled mill for rolling out the cathodes of fine gold. Ingots 14 in. long,  $3\frac{1}{4}$  in. wide, and  $\frac{1}{2}$  in. thick are rolled into ribbons 60 ft. long and 0.01 in. thick. All the melting of the refinery is done in a commodious room where four Rockwell furnaces are usually kept running at full blast. Oil as a fuel is used with excellent results, its economy being demonstrated by the fact that less than 4 gal. was consumed per hour per burner. In one month 600,000 oz. was melted at a cost of but \$60,

larly set aside. Since then satisfactory circulation has been effected by glass propellers, agitated by vertical rods driven by a small motor, and by placing the electrodes farther apart, the agitation was so conducted as to obviate trouble from mechanical admixture with the gold deposits. The proper interval was found to be a little over  $2\frac{1}{2}$  in. between anodes and cathodes, at which distance the deposition of gold was still effected in sufficient quantity by increasing the current density. After considerable experiment the following arrangement of gold cells was adopted. On a long soapstone table, 3 ft. high and nearly 5 ft. wide, 2 rows of porcelain cells, 12 each, are placed. Each cell contains 31 litres of electrolyte agitated by the glass propellers described. From the connecting strips of gold leading from the bus-bars, and bent as an inverted V over horizontal porcelain rods, 6 anodes and 8 cathodes are now suspended, 2

or 0.0001c. per ounce. After a successful trial run of about 100 continuous days, a clean-up of all the metal remaining in various forms was made, and on July 1, 1908, the plant was turned over. While from a chemical and metallurgical viewpoint the process had proved highly satisfactory, the cost of its installation and certain excessive operating expenses at that time were economic considerations which almost balanced the technical advantages it offered. From the start, studied efforts have been made to develop the maximum efficiency of the current in depositing metal on the cathodes. All improvements in the electrolytic procedure have since approached more nearly the ideal conditions and normal reactions, as far as the cost of current and reagents would permit.

A number of mechanical difficulties which were encountered at first have since been changed. The method of causing the electrolyte to circulate through the silver cells by the cascade system was abandoned. An expensive porcelain pumping and distributing outfit, which had been purchased as part of the equipment of the gold cells, was simi-

larly set aside. Since then satisfactory circulation has been effected by glass propellers, agitated by vertical rods driven by a small motor, and by placing the electrodes farther apart, the agitation was so conducted as to obviate trouble from mechanical admixture with the gold deposits. The proper interval was found to be a little over  $2\frac{1}{2}$  in. between anodes and cathodes, at which distance the deposition of gold was still effected in sufficient quantity by increasing the current density. After considerable experiment the following arrangement of gold cells was adopted. On a long soapstone table, 3 ft. high and nearly 5 ft. wide, 2 rows of porcelain cells, 12 each, are placed. Each cell contains 31 litres of electrolyte agitated by the glass propellers described. From the connecting strips of gold leading from the bus-bars, and bent as an inverted V over horizontal porcelain rods, 6 anodes and 8 cathodes are now suspended, 2

The decomposition of the electrolyte is more rapid in the

small cells than in the larger. For that reason the strength of the solution has to be watched more closely so that it may be frequently replenished, while the 250-litre tanks may be maintained at a more uniform density. It is of high importance that the deposit of gold on the cathode should be coherent. If the current density is high (100 amp. per sq. ft. or over), there should be 60 to 75 gm. of gold per litre in solution. With a lower current density, the proportion may drop to 40 gm. at 60 amp. Below this current density it is not economical to electrolyze crude gold bullion. With higher currents the decomposition of the electrolyte becomes more rapid, until a degree of density is reached at which the anode is attacked, but very little in comparison to the manner in which the current breaks up the solution of gold trichloride. It is therefore necessary to ascertain the exact proportion of gold in solution which is required for efficient dissociation and deposition at a given current density. Accordingly, titrations have been made at regular intervals. Samples of 1 c.c. are taken from each cell, the gold precipitated by ferrous ammonium sulphate, and the gold per litre determined volumetrically. Stock solutions of auric chloride, averaging 450 gm. gold per litre, are held in readiness in crocks carried about on trucks. Three times per day fresh strong solution of gold is added to the cells according to the amount determined by the chemist. A greater proportion of hydrochloric acid was found to diminish the resistance of the bath as well as to absorb chlorine at the anode whenever evolved to any large extent. But as the cost of this acid was a considerable factor, its percentage was reduced materially. The principal cause of its loss was due to the formation of silver and base chlorides, and as the percentage of base alloy increased, when hydrochloric acid was required, as well as gold trichloride. When the current density is increased more acid must be added.

During the four years in which this refinery has been in operation, many chemical and metallurgical problems were solved in the laboratory, where a complete analytical equipment was in daily use. Many of the radical changes which have since been made in the evolution of this electrolytic refinery were first tried on a small scale. Also a number of theories were exploded by the results of conclusive experiments. Much of the spirit of healthy competition, characteristic of commercial plants, was manifested in this government-owned and operated refinery, as almost every skilled workman took a keen personal interest in finding better ways of doing his own special work. Most of the improvements in the processes employed have emanated from the practical suggestions of the experienced operatives whose collective ideas have brought many changes for the good of the service. As a direct result the efficiency of the plant has been almost doubled, while the force employed has been reduced nearly one half.

During the fiscal year 1908-9, the horizontal system of silver refining, called the Thum process, as first installed, was almost entirely discontinued. A reversion to a modification of the Moebius process was necessitated by the relatively high consumption of power and  $\text{HNO}_3$  required by this method. As the slabs of doré silver were laid in the horizontal basket with the graphite cathodes in the bottom of the cell, the action of the current was only upon the lower sides of the anodes. In order to obtain a large output of fine silver from these Thum cells, the current was increased with the result that a rapid decomposition of the electrolyte ensued. More nitric acid was required, raising the cost considerably, while the canvas lining of the anode baskets was quickly eaten through by the acid. Against these drawbacks was the one advantage that the anodes were entirely decomposed into silver and base nitrates with the residual gold and insoluble impurities separated in the canvas basket. In this form it could be readily prepared for melting into high-grade gold anodes for the Wohlwill process. In the old Moebius method the unattacked tops of anodes which were suspended above the solutions required a second melting and electrolyzing.

From 12 to 18 cells were transformed to the vertical system. Gold strips leading from the bus-bars were bent over wooden rods, and from these gold hooks 36 anodes in 9

rows of four each suspended in a solution of silver nitrate containing 30 gm. silver per litre and 20 gm. of  $\text{HNO}_3$  acid together with a small percentage of copper nitrate. The electrolyte was maintained at about this strength by fresh additions of its components according to determinations made by volumetric methods. The entire volume of electrolyte in each cell averaged 137 litres. Forty cathodes of fine silver are suspended from horizontal rods at a distance of nearly 3 in. from the anodes and opposite them. They are 4 in. wide, about 0.2 in. thick, and are immersed nearly 9 in. in solution. The composition of the anodes is about 300 parts gold, 600 silver, and 100 base. This method differs from the old Moebius method, as already described, in that the muslin bags which formerly encased each anode have been done away with. The electrolysis of each anode is now carried to the point where the gold core remains as a black and brittle mass, which is carefully removed so as to prevent any considerable amount of its mass from falling into the slime in the bottom of the cell. Before plunging the cathodes into their acid bath, they are first given a coat of silver chloride mixed with copper nitrate, which forms an adhesive sticky coat covering the cathode. This largely prevents the deposit slipping off the surface. Glue is also used to facilitate the retention of the fine and fern-like silver as it deposits upon the cathode. After the silver is about  $\frac{1}{2}$  in. thick, the cathode is removed, and the deposit scraped off with a sharpened piece of silver. The electrode is then replaced. The fine silver recovered from these cathodes is then washed in a centrifugal machine, dried, and melted into fine bars. About every ten days the electrolyte is drawn off and the silver precipitated upon slabs of copper in a wooden tank, and the red metal is later recovered as cement copper by precipitation with iron. The Thum process is still employed for the treatment of the unattacked tops of anodes of doré metal and the slime from the silver cells. These are packed in 7-oz. duck, connected with a candle-shaped piece of silver which produces the contact, and the transmitted current does the rest, the silver passing through the diaphragm and depositing as beautiful crystals upon the cathodes of graphite in the bottom of the cells. The deposited silver is removed from time to time by rubber scoops, washed, dried, and melted into fine bars, while the gold remaining in the basket, ranging from 900 to 950 in fineness, is mixed with crude gold deposits and put through the Wohlwill process.

The one great drawback of the electrolytic refining of gold was the fact that nearly all bullion treated had to be operated upon twice. Anodes for the Wohlwill process must not contain more than 6% silver, otherwise a thick pasty white coating of silver chloride forms upon the surface of the anode, protecting it from further decomposition. Although this chloride was scraped off as rapidly as the refiners could remove it, the current would divert most of its energy to depositing gold out of the specially prepared electrolyte instead of attacking the anodes. One thousand ounces of crude gold, containing 800 parts of fine gold, would be alloyed with 2000 oz. of refined gold bars in order to produce anodes averaging 933 in fineness, the remainder being silver and base metals. It will be seen that the necessity of alloying more than two parts of pure gold to every part of crude gold of average fineness as received from the depositors, was a serious handicap. The metal had to be melted, alloyed, and electrolytically parted; then, from two-thirds to three-quarters of its weight had to be re-melted and re-refined with the next batch of crude bullion, and finally melted into bars for coinage. This meant that practically every ounce required three meltings and two separate partings, when the treatment of anode tops, slime, and the precipitation of electrolytes was taken into consideration. The desideratum was a means of materially reducing the amount of fine gold alloy which was required to bring the anodes up to 930 or 940 fine.

#### WHAT THE PULSATING CURRENT ACCOMPLISHED

The value of reading reliable technical journals and thereby keeping posted upon progress along the lines of whatever applied science one may be engaged in as a vocation

was demonstrated by the adoption of a radical improvement in the electrolytic refining of gold as suggested in a journal in the spring of 1910. A single-phase alternator was connected in series with a direct-current generator, and the combined currents were led by a single conduit to the bus-bars which distributed the current to the gold cells. The alternator was regulated by careful experimenting until it produced a voltage of lower potential than that evolved by the direct-current generator. In practice the latter developed in each gold-parting cell 1.3 volts to 1 volt produced by the alternator. By the superposition of an alternating current of lower E. M. F. upon the direct current in the above proportion, the current evolved moved continuously through the circuit after the manner of a direct current, but with the difference that its potential rose and dropped with a pulsating effect, according to the influence of the 60-cycle alternator. A notable improvement was accomplished by this peculiar current. Each pulsation apparently imparted a distinct jolt to the silver chloride which accumulated on the anode, causing it to dislodge and fall to the bottom of the cell. This enabled the ions to migrate more rapidly from the anode, greatly increasing the dissociating efficiency of the current passing through the cells. It became possible to largely increase the anode current density. Where the direct current had run at a current density of 80 amperes per square foot, the pulsating current permitted the employment of a net amperage of 110 to 120 per square foot, an average increase of 40 to 50% in the efficiency of the current. The ammeters used did not register the alternating current, as will be readily understood, but represented the net amperage in terms of direct current, from which the current density per square foot was computed.

In addition to the increased efficiency of the cells, a still greater advantage was obtained by enabling the refiners to operate successfully upon crude gold bullion containing only 800 parts of fine gold per 1000. Excellent results have since been accomplished by electrolyzing anodes of 850 fineness. This innovation has largely done away with the wasteful method of alloying from 2 to 2½ parts of fine gold as described. 'Black gold,' the anode product of the Thum cells, ranging from 900 to 950 in fineness, is now blended with lower grade gold deposits to bring the resultant alloy up to about 850 fine. Further advantages have been found to be given by the pulsating current. Formerly, about 10% of the gold anode dropped to the bottom of the cells, and after being recovered in the slime, required a second melting and refining. Now but little more than 1% of the gold falls into the slime. With greatly increased current density, there is no marked evolution of chlorine, as was unpleasantly evidenced whenever the direct current was increased. Also the amount of hydrochloric acid used in the electrolyte has been reduced more than one-half, except when unusually base bullion is being parted. When the pulsating current is passing through the cells electrolysis may be effected with the electrolyte at a much lower temperature.

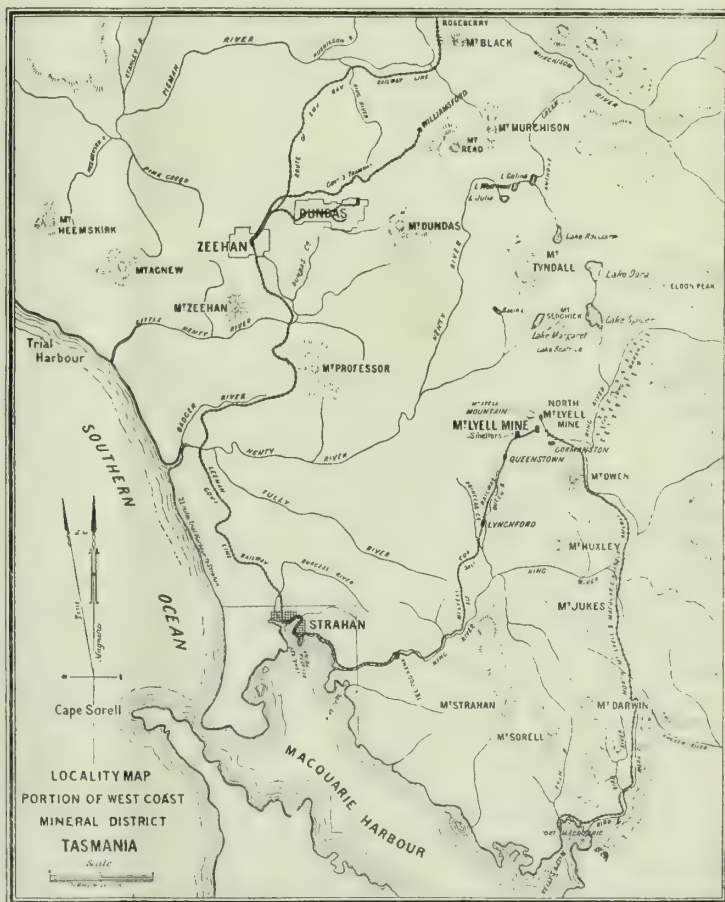

In Victoria at the present time one of the most promising things is the Central Plateau, on the famous old Ballarat field. This mine, after shaft-sinking to a depth of 600 ft. to cut a celebrated vein from which the old Star of the East company paid many dividends in the nineties, has driven north on the strike of the vein, and has found a 30-in. shoot of quartz containing about ½ oz. gold per ton. About 240 ft. of ore has so far been proved and there is about 1000 ft. of virgin ground ahead. The shaft is to be sunk another 100 ft., to endeavor to find the vein at a lower level. The liabilities of the company amount to some \$17,000 and recently the price of the shares has risen from 85c. to \$2.40.

## The Mount Lyell Fire

MELBOURNE CORRESPONDENCE

Into the details of the great disaster at Mount Lyell, Tasmania, whereby 42 miners lost their lives, it is not necessary to enter. The subject lends itself to full treatment in the columns of daily newspapers dealing in the purely personal and in the sensational, rather than to those of a journal that is devoted to the impersonal and technical, but there are certain features of it and certain circumstances in connection with it that are of interest from the scientific point of view and from those concerned in the management of large mining ventures.

Work was proceeding as usual when a fire broke out very suddenly at the 700-ft. level; owing, it is believed, to

a break in the electric motor operating the pump, firing the insulation and igniting the timber. The heat of the fire made the shaft a flue through which a dense volume of smoke made its way to the surface, and eventually the shaft became unworkable below the 500-ft. level. The mine being a wet one, the fire was not expected to be very serious, but the fumes given off were deadly, and 42 men thus lost their lives. Unfortunately no organization existed to cope with an outbreak of fire or its consequences. Some helmets were obtained for use by rescue parties, but the miners had had no experience or instruction in their use, and the firemen who arrived on the scene had no knowledge of the mine, without which, attempts at rescue were as likely to prove fatal to the would-be rescuers as to succor the men imprisoned in the levels. The danger of the rescue work was increased by the eddies set up by the ventilation, the smoke in one case going up a raise, proceeding for some distance along the level, and going down a winze. Many more lives would have been lost had it not been for the common sense and presence of mind of one of the men operating the compressed air. Noticing the air had no effect when directed full against the smoke, he turned it against the face, toward which he instructed the

men to work and keep as close to the wall as possible. Fifty men were saved in this way.

In connection with the disaster, J. J. Mahoney, president for Tasmania of the Federated Mine Employees' Association, has made some serious charges against the company. He asserts that men have been leaving the mine during the past four months because of the constantly increasing neglect of proper precautions in working. The miners remaining elected, as they were entitled to do under the mining law of the state, check inspectors to examine the mine and report upon its safety. Mr. Mahoney states that the company blocked an examination of the mine by these men to the utmost of his ability, and after their inspection would not allow them to write a report in the company's book. These check-inspectors insisting on the necessity of a second exit, the miners at a meeting resolved not to re-enter the mine until their representatives had been permitted to make an untrammelled inspection and to this the company agreed, but, in Mr. Mahoney's view, too late to avert the disaster. He further states that the false economy of the company in employing only one man to look after both the pump-house at the 700-ft. level and the one at the 1100-ft. level was alone responsible for the fire getting a hold, with such terrible consequences. Naturally the man could not be in both places at once; and when the fire broke out, he was either at the other level or was traveling between the two. The final and worst accusation made by Mr. Mahoney are best given in his own words:

"Why were the men not notified in terms of urgent warning that the fire was serious? The pump-house man knew it at 10:45, and must have telephoned up to the officials. It was their place to give strict orders for the men to leave immediately, and see that they obeyed. Every man could have been saved. It takes only half an hour to lift the whole shift. That half hour would have meant at the outside 11:30 a.m. The time when the fumes were at their worst was about noon, or 12:10. When the rush to get out took place they were worse in the shaft than elsewhere. The shaft was the only means of exit. That was why the men rushed there. The other means of exit had been blocked for some weeks, the mullock pass having come together. The men say they would have used it had the company cleared it, as it ought to have been done immediately it was blocked."

The matter is to be the subject of an investigation by a Royal Commission appointed by the Tasmanian government. As the fire could not be extinguished and all hope had been abandoned of any of the men still in the mine having retained any vestige of life, the mine has been sealed in an endeavor to put an end to the fire, but, with doubtful wisdom, it has been twice unsealed in order to see what progress had been made. It is now sealed for a third time, and it is hoped that this time a sufficient period will be allowed to elapse to allow the fire to burn itself out. The process of flooding the mine has been very slow, owing to the shortage of water. Even, however, when the fire has been ultimately subdued and the mine has been freed of the noxious fumes that now fill it, and when the water laboriously pumped in has been pumped out again, the troubles of the company will by no means be at an end. Not only will the shaft, and the various drifts, winzes, and raises have to be re-opened, re-timbered, and repaired; but also there is a certain psychological difficulty to be overcome—the certainty that the men will refuse to start work in the mine again till every one of the 42 dead bodies has been brought to the surface. As some of these bodies may never again see the light of day, there is no future for the mine unless either the miners change their intention not to resume work until the last body has been recovered, or men are obtained from outside who are more callous concerning the past.

Meanwhile, the company, being deprived of the North Lyell ore, is obtaining fluxing material from the open cut at the Lyell Tharsis mine, and is mixing it with a small percentage of boulder schist from the North Lyell open cut. As the Tharsis ore is not so good a flux as the North Lyell, and has a value of considerable less than 2% as compared with the North Lyell value of 6%, it is not

to be supposed that present working is being done at a profit. The value of the Mt. Lyell pyrite is only  $\frac{1}{2}\%$ , and the value of the mixture with Tharsis ore may be put down at 1%. The company deserves credit for the heroic efforts it is making to keep all the men employed, with no prospect of profit to itself.

When all the adverse circumstances are taken into consideration, the necessary slow recovery from the labor troubles at the close of last year, the shortage of labor, and the frequent interruptions of work for this or that or the other trivial cause, the Mt. Lyell company's figures for the half year comprising the second and third quarters of 1912 are remarkably good, the output of nearly 3200 tons giving a profit of about \$500,000.

## Working Costs at the Shannon Mine

By J. W. BENNIE

\*During the year ended August 21, 285,210 tons of ore was mined from the property of the Shannon Copper Co. at Metcalf, Arizona, of which 42,125 tons came from open-pits, 216,183 tons from the intermediate levels, 26,006 tons from what is known as the Carter (or lower) level, and 897 tons from development on outside claims. The grade of ores obtained from the lower levels, while not as high as anticipated, is much better than the average of the mines. This is a factor which will have an important bearing on the future of the mines.

### DEVELOPMENT AND ORE RESERVES

During the year more than normal expenditures were made for exploration and development, 11,031 ft. of work being driven during the year. Of this, 4600 ft. of drifts was driven on the lower levels, 796 ft. on upper levels, 4700 ft. on the intermediate levels, and 880 ft. on outside workings. Development on the lower levels of the mine has been of an encouraging nature, and while at present only 125 tons per day is being mined from these levels, this output will be doubled in the near future. Development on the outside claims will be continued during the coming year. Nothing of any consequence has been opened by previous development, but there is still a possibility of good ore being obtained in quantity from the El Paso and adjoining claims.

Important new work to be commenced during the coming year will be an exploratory adit to be driven from a point 25 ft. above the ore-bins in Chase creek for a distance of 1500 ft., cross-cutting the main ore formation at a depth of 300 ft. vertically below the Carter level. This adit was suggested ten years ago, and while discussed at various times since then, it is only now that it is considered warranted as a justifiable development scheme.

The policy of confining development expenditure to searching for new orebodies instead of opening known ones has been continued during the year, and with gratifying results, especially in the lower levels. In previous reports I have pointed out it would be very expensive to open ore reserves, with no advantage except that of being able to approximately estimate them. Geological conditions are better understood as each year passes, and it is this better understanding, added to the results of recent development, that warrants the statement that there is a probability of an extended life for the Shannon mines, which was heretofore doubtful.

### COSTS

The cost of mining per ton was lower by 5c. than that of the year previous, the saving being in lower cost of extraction and cheaper timbers. This saving would have been greater, but miners' wages were increased in June, thus adding to the labor bill. There was also an additional expenditure of 7c. per ton on ore extracted during

\*From the annual report of the Shannon Copper Co. for 1912.

development. The total costs, therefore, were approximately the same as last year. During the coming year no material change in costs is anticipated. The only additional extra expenditure contemplated is for new office for engineers and superintendents, the present quarters being overcrowded. All operating departments—that is, the mines, concentrator, smelter, power-plant, and transportation department—have shown marked improvement both in their physical condition and in their ability to operate at lower cost. This was reflected in the cost of producing copper, as will be seen by the tabulated figures below, taken from the report of the president of the company, N. L. Amster. In the month of April copper was produced at a cost of a fraction over 10c. per pound, including every item of expense, both Eastern and Western. In June, however, a new scale of wages was put into effect by the Shannon as by every other mining company in Arizona, and this meant an increase in the monthly payroll of approximately \$10,000, or the equivalent of about 0.7c. per pound of copper. The rising copper market also made it tempting to mine and ship to the smelter ores of a grade which on a lower copper market were not considered workable and were not mined; this, too, tended to increase the costs during the last quarter of this fiscal year, as is shown by the following figures:

	Cost per lb. (cents).	
	1911-12.	1910-11.
First quarter ended November 30.....	11.8	11.009
Second quarter ended February 28.....	10.93	11.923
Third quarter ended May 31.....	10.55	11.085
Fourth quarter ended August 31.....	12.47	12.287

Notwithstanding, however, the increased wages and the lower grade of ore shipped toward the end of this fiscal year, the average costs per pound of copper produced for the year were a little lower than those of preceding years.

Year.	Cents per lb.	Year.	Cents per lb.
1911-1912 .....	11.42	1907-1908 .....	12.6
1910-1911 .....	11.58	1906-1907 .....	14.5
1909-1910 .....	12.1	1905-1906 .....	14.6
1908-1909 .....	12.2		

Liberal expenditures were made during the year for development and exploration work, amounting to \$90,415.74, and charged, as usual, to costs. This is 33% more than was spent in 1907 on a 22c. metal market, and more than double the development expenditures of any other year in the company's existence, and the results were satisfactory.

#### REDUCTION WORKS

There have been few changes in the blast-furnace plant; it was thoroughly overhauled during the year and is now in first-class condition. The cost of smelting was materially reduced during the year, due to the reduction in amount of coke and flux used, and less cost of power. During the coming year experiments in the use of basic, instead of acid-lined converters will be carried out, and a material reduction in converting costs is expected. These experiments will be undertaken as soon as a new blowing-engine, which is considered essential, is erected. The costs of concentrating show a marked improvement over the previous year. The supply of concentrating ores is, however, very irregular in quantity, and the operating costs, therefore, are much higher than otherwise would be the case. It is hoped to remedy these conditions during the coming year. Owing to lower freight rates and cheaper fuel oil, costs for power were materially reduced during the year.

#### LEACHING

Experiments commenced last year, leading to an attempt to solve the economic treatment of low-grade semi-oxidized ores, have been continued during the past year, with every reassurance that the problem will be solved. Several months time was wasted in the anxiety to rush these experiments, and we are not, therefore, much farther forward than we were last year. We can state positively that the process we are experimenting with is successful to the extent that it renders the major portion of the copper content soluble in water.

## The Swansea Smelter

The Clara Consolidated Co., formerly operating at Swansea, in northern Yuma county, Arizona, has recently been reorganized as the Swansea Consolidated Gold & Copper Mining Co., for which C. Clerc is general manager and W. H. Seamon smelter superintendent. The smelting plant has been overhauled and was recently blown in. Copper is now being produced at the rate of 600,000 lb. per month from custom ores as well as from those produced by the company. For the following brief description we are indebted to the *Parker Post*.

The smelting plant consists of one 750-ton water-jacketed blast-furnace with 42 tuyeres; the blast enters the furnace 33 in. above the bottom; the pressure is 10 oz. at the powerhouse. The blast-furnace stack is 7 ft. diam. and 125 ft. high. There are two converter stands, capable of turning out from 45 to 50 tons of metal daily. The converters are 8½ ft. long, have cast steel heads and tops, and are electrically operated. A 40-ton electrically operated crane

WESTERN ARIZONA.

(Swansea is at final 'r' in Parker and is connected with Bouse by a railway.)

completes the equipment in this department, there being one main and two auxiliary hoists.

The system of tramways and of handling the custom ores is to be changed by the new management as rapidly as possible. Already a decided improvement has been made in handling the custom ores after they are dumped near the sampling mill. A small hoist has been installed and they are elevated to the tramway on 5-ton cars. Formerly it was necessary to shovel this ore into the cars from the platform. In time the tramway system will be entirely eliminated by the installation of conveyors, which will handle the ore faster and at less expense than under the present system.

Construction of a reverberatory is under way, and its completion is being rushed as fast as possible. It will have a capacity up to 400 tons every 24 hours. The dimensions of the furnace are 19 by 108 ft. When completed the capacity of the Swansea plant will be over 1000 tons per day.

The power-plant contains two 250-hp. boilers. A 15,000-cu. ft. Nordberg blowing-engine furnishes air for the converters, two 7½-ft. blowers for the blast-furnace, one 11½-ft. blower, operated by a Hamilton-Corliss compound engine, which was installed to increase the air capacity, is

not being used since it was found that the furnace was receiving too much air. A 300-kw. D.C. Westinghouse motor, direct-connected, furnishes power for the tramway, electric lights, and miscellaneous purposes. A 150-kw. A.C. belt-driven Ideal motor furnishes power for a pump at the Bill Williams river. This pump supplies the water required for operating and domestic purposes. There are two pipe-lines, one 6 in. and the other 3 inches.

## Mineral Industry of California, 1912

The value of California's mineral product for 1912 will reach a total of well over \$91,500,000, being an increase of \$4,000,000 over the production of 1911, according to a preliminary report by W. H. Storms, State Mineralogist. Great activity has been evident in the mineral industry, and an increased production will undoubtedly be shown in every branch, with the possible exception of copper (owing to the fact that the fume trouble has not been satisfactorily solved as yet), but the value of the copper produced will show a large increase, due to the advance in the price received during the year, the average being close to 16c. per pound, as against 12½c. per pound received in 1911. A conservative estimate of the leading mineral products for 1912 is as follows:

Petroleum, 87,000,000 bbl.....	\$41,000,000
Gold .....	20,000,000
Cement .....	10,500,000
Copper .....	5,000,000
Crushed rock, used for all purposes.....	4,000,000
Brick of all kinds.....	2,500,000
Borax .....	1,500,000
Natural gas .....	1,500,000
Quicksilver .....	750,000
Silver .....	750,000
Lime and limestone .....	750,000
Mineral water, salt, and clay pottery.....	1,250,000
Miscellaneous minerals .....	2,000,000
Total .....	\$91,500,000

The remaining 26 minerals, listed as miscellaneous, which were produced in 1911 had a total value of \$1,800,000. Many of them are known to have had a greatly increased output during the year just passed, probably far exceeding the estimated \$2,000,000. Some minerals which have been receiving considerable attention from capital recently are: bauxite, for the manufacture of aluminum; various iron deposits throughout the state; barytes, feldspar, natural asphalt, potash and nitre deposits, tungsten, and vanadium. While practically all the asphalt used in the state is a refined product, it is often listed with the total mineral output, in which case the total figure would approximate \$95,000,000.

California ranks first among the states west of the Mississippi river in the value of its mineral production, according to the United States Geological Survey. In former years California's claim to distinction as a mineral producer rested on its output of gold, in which, in fact, it held first place in 1911, although in recent years it has usually fallen behind Colorado in the production of gold. The premiership of gold in the state has, however, been succeeded by petroleum, the value of which in California exceeds that of gold by 94% and gives the state first place among the states in the production of crude oil. California leads also in the production of asphalt, of platinum, and quicksilver, and enjoys a monopoly in the production of borax and magnesite. It is second in the production of tungsten ores, third in the production of cement, and sixth in the production of copper, and stands well up among the states in the production of a number of less important minerals. The total value of the mineral production of California in 1911 was \$90,517,566, compared with \$86,721,069 in 1910. The average copper content of the ore production in California is higher than any other state or territory, with the exception of Alaska.

## New Power Plant, Scottish Gympie

The new power plant at the Scottish Gympie gold mine, Gympie, consists of a Belliss & Morecom compound horizontal-impulse, mixed-pressure turbine, running at 1500 revolutions per minute, direct coupled to and on the same bed-plate as a 500-kw. compound British Westinghouse generator, 220-240 volts. This generator, which is the first large direct current generator of the type introduced into Australia, while utilizing the available exhaust steam from the mill engine, pumps, and other existing engines, supplies electric light for surface and underground, and power to drive 25 stamps in the mill, as well as to drive two compound air-compressors (vertical, by Belliss & Morecom), with a total capacity of 2000 cu. ft. of free air per minute at sea-level to a final pressure of 95 lb. gauge. Each compressor is mounted on the same bed-plate, and direct coupled to a British Westinghouse 200-hp., 220-volt direct current, shunt-wound, inter-pole motor. The compressed air thus supplied is used for driving the rock-drills and other machines. The condenser is by Belliss & Morecom, complete with a two-throw Belliss-Edwards air pump, driven by an electric motor, and is capable of dealing with 20,000 lb. of exhaust steam per hour, with a vacuum of 27 in. barometer, or 30 in. when supplied with cooling water at 80° F. The machine is now working with a load of 484 kw. The water from the condenser is used in the mill.—*Queensland Government Mining Journal.*

## Electrolysis of Nitric Acid Solutions of Copper.

By J. H. STANSBIE

\*The object of the investigation was to find the cause of the failure of the current to completely deposit copper from its nitric acid solutions. A platinum cathode thickly plated with copper was rotated in a solution of nitric acid containing less than 0.1 mg. of nitrous acid, and was then allowed to remain at rest in a similar solution for the same length of time. In one pair of experiments 15.4 mg. of copper was dissolved from the rotating cathode, and 3486.3 mg. from the stationary cathode. This remarkable difference is no doubt due to increased action brought about by the accumulation of nitrous acid or nitrate in the layer of liquid in direct contact with the metal, which cannot take place while the metal is being rapidly rotated. No current was allowed to pass in either case.

In the electrolysis of nitric acid solutions of copper it is found that nitrous acid is formed in the solution, and that the presence of this compound prevents the deposition of the last traces of copper from the solution. The influence of the nitrous acid increases with the concentration of the nitric acid. This is shown by experiments with solutions containing varying weights of nitric acid to the same weight of copper. The copper left in solution was found to increase with the concentration of the nitric acid and the accumulation of nitrous acid in the solution. The presence of free sulphuric acid in the solutions retards the formation of nitrous acid, and it is probable that a nitro-compound is formed from the two acids which is less effective in promoting the dissolution of copper from the cathode than nitrous acid alone. It is quite clear that the rotating cathode is much more efficient than the stationary one, and that all but the merest traces of copper can be deposited from dilute nitric acid solutions containing sulphuric acid, if the cathode is promptly removed and washed, preferably while the current is passing and the cathode rotating. This can be done by directing a jet of water on the cathode from a stationary wash-bottle while the beaker is being lowered to break contact, or by means of a suitably arranged tap funnel.

\*From a paper read before the Faraday Society, London, England.

## Discussion

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment. Insertion of any contribution is determined by its probable interest to the readers of this journal.

### What are Mining Profits?

The Editor:

Sir—If we agree with the statement of Mr. Finlay that “the profits of mining are just like any other profits,” then it would seem unnecessary for Mr. Cabell and Mr. Speer to be traveling through the West studying the question of how to estimate depreciation on oil lands and mining properties so as to arrive at a basis for levying the corporation tax. In view also of the decision of Judge Polk in the case of *Stratton's Independence v. F. W. Howbert* this seems to be futile.

It may readily be conceded that the removal of ore, while undoubtedly lessening the value of a mine, should not be classed as depreciation in making up accounts for the purpose of the tax. Depreciation is a technical term. In a manufacturing business, for instance, it is customary to charge against profit a proportionate sum year by year as depreciation on buildings, plant, and machinery according to their estimated life or usefulness, and such is a proper charge or cost of producing such profit.

Again, if a corporation were dealing in shares or something else of a fluctuating character it would be proper in arriving at the profit to offset any depreciation in value of part of the investment against any appreciation on the other part. On the latter basis it is possible to contemplate the contingency when from the fall in price of some metal there would be an actual depreciation of value of ore in a mine. The ore extracted from a mine, however, does not come within this category. But while it should not be classed as depreciation, it does not follow by any means that it is all income or profit, for in no other business would it be permissible to include sales or product on one side of the account while ignoring one of the costs of production, by whatever name you may call it, on the other.

Take the following as an extreme example. A corporation invests \$1,000,000 in the purchase of timber (it does not buy the land on which it is growing). After payment of all expenses it receives back the original investment only at the rate of \$100,000 per annum. It will hardly be contended, I imagine, that it should pay any excise tax at all. Logically, as the amount of ore to be extracted cannot be predicated, the actual profit from a mine cannot be ascertained until after the capital expended in the purchase, development and working, and a proper allowance for depreciation of equipment has been returned in full.

ERNEST V. ORFORD.

Delamar, Idaho, November 15.

### Filter Patent Litigation

The Editor:

Sir—My interests being affected by the recent decision sustaining the Moore process patent, I called the attention of my patent counsel to the editorial appearing in your issue of November 23, having got the impression from reading the editorial that a judgment of the Circuit Court of Appeals for one district did not affect one who might be an infringer in any one of the other eight districts. The advice that I have received is to the effect that any such impression is entirely erroneous and that while one taking the pains to properly analyze and weigh your editorial, paragraph for paragraph, is likely to reach the conclusion that you intended no such construction put upon it, yet a mere cursory reading is likely to convey such impression to others as it did to me.

I am given to understand that a decision by one Circuit Court of Appeals is in about ninety-nine cases out of a hundred recognized by every other Circuit Court of

Appeals as *prima facie* for the granting of at least a preliminary injunction, and that the instances are very rare when the judgment is not considered final, or in effect the same as if it were the judgment of the United States Supreme Court. The present Circuit Court of Appeals, I am advised, was established simply to relieve the United States Supreme Court of consideration of patent and other causes.

I have at all times been willing to concede that George Moore solved the slime problem but one of those who it now turns out was evidently arguing for ‘revenue’ only, succeeded in convincing me that the Moore process patent would never be sustained by the Courts, and I must confess that with the great number of contrivances previously patented and which were claimed to be “perfect anticipations” of Moore’s patents, that I concluded to take my chances with the somewhat extensive list of persons who had evidently become similarly convinced.

It now appears that Moore protected his position fundamentally by obtaining a ‘process patent,’ and that the steps of his process are not anticipated by any one of the apparatus patents which I had presented to me as “perfect anticipations” of Moore’s process patent. I think that I have now discovered just about where I am at, and possibly the publication of this letter might serve a useful purpose to others who have been sailing in the same boat with me.

R. R. REUTLINGER.

Philadelphia, November 30.

[We regret that our editorial should have been misunderstood even by one reading it hastily. In pointing out the possibility of further litigation we had no intention of suggesting that there was more than a chance that the decision just rendered would be reversed. Indeed the latter seems entirely improbable, and we have therefore urged that from now on negotiation rather than litigation is in order. We are glad to see that our correspondent’s attorney agrees with us in analysis of the case.—EDITOR.]

### Persistence of Ore in Depth

The Editor:

Sir—The recent articles and letters on this subject seem to have wandered far from the original paper which prompted them and which was apparently based upon the fact that, in the United States, the “new discoveries are not equaling the depletion of those already developed.”<sup>1</sup> There seems also to have been a desire to provoke a discussion as to whether new discoveries could be made by more scientific prospecting.

Several of the writers approach the subject as though the only direction in which to search was downward, and pour further ridicule on the already ridiculous suggestion that veins should improve or continue indefinitely. The discussion has brought-out much information, but there is a want of detail, and we have, after all, only arrived at the conclusion that some veins become richer, some become poorer in depth, some even have more than one change from rich to poor, and the reverse; but, in the case of those that have become poorer, we have no definite information as to whether this is final and is due to depth alone or to other causes.

The details given by W. H. Storms<sup>2</sup> prove conclusively that, in many instances, the mines on the Mother Lode improve in depth, but his statement that “proper geologic conditions seem to be more important than all other considerations” is disappointing, for he leaves us completely in the dark as to what those proper geologic conditions may be. If when a vein becomes poor in depth there is undoubted evidence that we have reached the roots of that vein, obviously we cannot reasonably expect an improvement at a still greater depth; but, unless we have reached the roots, in the absence of adverse chemical or physical

<sup>1</sup>Garrison, F. L., *Mining and Scientific Press*, September 21, 1912.

<sup>2</sup>Storms, W. H., ‘Possibilities of the Mother Lode in Depth,’ *Mining and Scientific Press*, October 12, 1912.

reasons other than those due to depth, then the experience on the Mother Lode and elsewhere would seem to indicate that, by still further sinking, a rich zone may be again encountered. There is a limit, of course, to sinking, just as there is to exploratory cross-cuts. The collecting of more instances of improvement or impoverishment of veins in depth will not help in this matter. What is wanted are complete geological descriptions of the veins in the upper and lower levels, and, where possible, some idea of the extent of erosion. George E. Collins<sup>3</sup> says that "prospectors do not usually sink on barren veins in order to find out what is below. Ordinarily prudent people, as a rule, only sink on veins which show at the surface evidence of productiveness." There have been notable exceptions to this, and there are likely to be more. Mr. Storms<sup>3</sup> gives instances of people sinking on veins to 100, 600, and even 1000 ft. before they struck profitable ore.

The Treadwell mines in Alaska are notable instances of improvement and impoverishment succeeded by further improvement in depth, and it is confidently expected at these mines that "such ore as has been mined from the surface to the lowest levels of the mines will continue to a much greater depth."<sup>4</sup> The case of the Mary Murphy mine mentioned by Mr. Collins<sup>3</sup> would be instructive if we had full details, including, of course, evidence as to erosion, for it is not merely depth from present surface about which we want information, but also to know whether much or little has been eroded.

In view of T. A. Rickard's statement<sup>5</sup> that "the most persistently rich lodes are in Archean and Algonkian rocks; they are associated with acid eruptives of the granitic type; they are presumed to be in their primary condition, that is, they owe little or nothing to the secondary enrichment observed within the water-zone", it is a little disconcerting to read later in the same article: "It is fair to ask the mining geologist to remember that it is only the enriched portions of a lode that have economic value to the miner and that such enrichments represent a concentration or re-precipitation necessarily more recent than the lodes as first formed." I have, of course, read the whole of the paragraph and note the question by Mr. Rickard, but would respectfully submit that there have been exceptions and there may be more, including that "barren outcrop at A" mentioned by Malcolm Maclaren.<sup>6</sup> Mr. Rickard cannot go so far as to say that Mr. Maclaren would be quite unjustified in sinking on this vein or he would have to say that much of the bolder work on the Mother Lode prospects was unjustified, and yet—they have become mines!

It is easy to understand why deposits associated with Tertiary eruptives should not continue to great depth, but the point that has not been touched on, except by Mr. Maclaren, is as to whether the top of a valuable deposit may be a poor or even barren vein. As it is admitted that there are zones of relative richness and poorness, obviously we can assume that all possibly profitable veins have not been conveniently eroded to their payable zone.

The great importance of the andesites as goldfields has been pointed out by Mr. Maclaren,<sup>7</sup> and there would appear to be no reason why veins in andesite should not also have poor or even barren outcrops and yet be richer in depth.

The article by Mr. Rickard<sup>8</sup> was prompted by F. Lynwood Garrison's paper before the Toronto meeting of the Canadian Mining Institute, and that paper, judging from Mr. Garrison's letter,<sup>1</sup> was written with a view to encouraging discussion on scientific prospecting. This matter of the improvement of outcrops in depth is one of great importance to the scientific prospector or mining geologist, for

whom there would appear to be as much scope or more above-ground than under-ground, if new deposits are wanted.

The possible improvement of lodes in depth (apart altogether from alteration due to ordinary weathering, the water-zone, or the added influence of air-borne sea-spray and manganese, etc.) is of more than mere academic interest, though that would be sufficient to justify a discussion. I don't plead for the opening up of every barren or even poor vein, but I maintain that we have definite evidence that some of them may improve, and though, to make use of the metaphor of Mr. Rickard,<sup>8</sup> "you can't expect a man possessed of unusual vitality at 90 to continue with unabated force for another half-century", still his energies may continue thus for some time longer; anyway, be sure that he has reached that advanced age, and then when his 'time' comes he may die from any one of the numerous and usual causes—even impoverishment, but don't forget that a younger man may suffer from any one of these numerous and usual causes—yes, even the last! but yet recover and have a long, useful, and profitable life; he is, so to speak, like a vein far removed from the zone of flowage.

There is still a third man to be considered, the one born to die young, a slight illness may carry him off, he is like one of the veins which have been eroded nearly to extinction and which cannot be expected to have a long life.

STEPHEN J. LETT.

London, November 28.

## Copper Review for November

By MISHA E. APPELBAUM

During the past month the domestic copper market fluctuated within very narrow limits. A fairly large business was done between 17 $\frac{3}{8}$  and 17 $\frac{3}{4}$ c. per pound. Between the end of November and the time the Producers' Association figures were published very little business had been transacted for the reason that most copper journals predicted an increase of 20,000,000 to 30,000,000 lb. in the visible supply of copper. As a matter of fact, the increase was about 9,000,000 lb., and, considering the decrease on the other side, practically no change took place in the world's visible supply. At the present moment, the American consumers have very little copper bought for their January to March requirements. The same state of affairs exists in Europe, and, in my opinion, as soon as the copper figures become known in Europe, a stampede will be caused, for it is hardly possible for the European or American consumers to keep out of the market for any length of time. This should result in a very satisfactory business at 17 $\frac{3}{4}$ c. per pound.

The outlook for the coming year, from a statistical standpoint, ought to be one of extreme satisfaction to the producers. The consumers of copper have enough orders on their books to run full for the next few months, and will therefore have to buy large quantities of copper, irrespective of how business may develop during that period. As to whether the business improvement will continue, or whether there will be a contraction due to the political outlook, is very hard to prognosticate. Inasmuch as the price of copper will be regulated more or less by the actual business conditions, it is difficult to state whether the price of copper will go higher. There is no doubt that the country is right for a cycle of business prosperity, and one can, therefore, but urgently hope that the Democrats will make use of their opportunity by introducing conservative legislation which should not seriously interfere with business and will at the same time do away with the existing tariff abuses.

THE September yield of the Melbourne Cope's Creek Tin Sluicing Co., Tingha, New South Wales, was 6 $\frac{1}{4}$  tons, inclusive of 1 ton 2 cwt. of second grade. The previous month's output was over 10 tons. No report has yet been made of the Coodardy and Poonah tinfields in Western Australia.

## Special Correspondence

### BUTTE, MONTANA

FINANCING EAST BUTTE.—FIRE IN THE WEST STEWART.—  
MINE INSPECTOR'S REPORT.

There is now no doubt that the East Butte Copper Co. will complete its purchase of the Pittsmont property. The stock consideration, 110,000 shares of East Butte, has recently been turned over to the Pittsmont interests, and over \$2,000,000 has been paid on the \$2,500,000 Pittsmont bond issue held by Pittsburg banks. The East Butte management deserves great credit for resuscitating what threatened to be a big mining and metallurgical fizzle. The Anaconda Copper Mining Co. has its central employment office and 'rustling card' system in full effect. The miners at large do not seem to object to it particularly, although the socialist minority in the union have held some stormy sessions to protest against the system. The Miners' Union, after some discussion, has referred the matter to the executive board of the Western Federation of Miners.

Monday the ninth fire broke out in a raise between the 1700 and 1500-ft. levels of the West Stewart mine. The 300 miners on shift were promptly brought to the surface. Jack O'Neill, superintendent of the Anaconda mine, and the

SCENE IN BUTTE.

most experienced fire-fighter in Butte was placed in charge of the fire zone, under the direction of John Gillie, general manager. Sixty fire-fighters with oxygen helmets were assembled, and succeeded in confining the fire to the vicinity of the raise. Within a few days, the workings were freed of smoke, and the fire was well under control. The Anaconda company has learned the importance of controlling such mine fires promptly, as the heavy sulphide ores when once heated will continue to burn fiercely with the access of very little outside oxygen. The fire is thought to have originated from a lighted candle carelessly left on the mine timbers.

A representative of the reorganization committee of the bondholders of LaFrance Copper Company was the only bidder at the sheriff's sale of the property on December 3. The property was bought for \$100,000. The stockholders will now receive nothing as they lose all rights through the foreclosure of the bonds.

Thomas F. Cole and associates of Duluth have offered to further develop the Butte & London property upon condition that they are given a 51% interest in the property in exchange for certain work done. They propose to sink the shaft 500 ft. deeper from the present level at 1130 ft. At this depth they will cross-cut north and south to the sidelines of the property. Mr. Cole and associates are interested in an adjoining property to the west, the Rainbow Lode Development Co., and to prospect their ground, they are desirous of taking advantage of the present depth of the Butte & London shaft.

William Walsh, state mine inspector, has issued his re-

port for the year ended November 30, 1912. He makes the statement regarding Butte, that during the past year development work exceeded that of any previous year by 57%. This development work was done mainly by the large operators, very little of it having been done by lessees and small operators. Mr. Walsh estimates that the introduction of electric power in and about the mines will finally mean a saving in production costs of 1c. per pound of copper produced. The report shows that throughout the state there were 47 fatal mine accidents during the year, about 0.3% of the number of men employed.

The United States Assay Office at Helena received \$136,695 during November from Montana counties. The big producers were Madison, \$62,000; Lewis and Clark, \$27,000; Fergus, \$22,000; Chouteau, \$15,000; and Ravalli, \$5000.

### JOHANNESBURG, TRANSVAAL

SEPTEMBER RETURNS.—FAR EAST RAND.

During the month of September the average recovery per ton of ore milled on the Witwatersrand was 28s. 7d. per ton as compared with 28s. 9d. per ton for the preceding month of August. This is the first time since last January that the recovery has gone back, for month by month since the beginning of the year the average recovery per ton milled has increased. It is not at all an easy task to explain why the recovery has improved to such an extent after such a long period of decline, because as a matter of fact the recovery value, as a rule, declines with the depth. What few exceptions there are to this rule cannot be deemed sufficient to bring about such a change in figures as this year has shown. The fact that working costs per ton have advanced to almost the same extent as the recovery would almost seem to indicate the existence of selective mining to a far greater extent than formerly. In the case of the East Rand Proprietary Mines (one of the three mammoth gold producers on the Rand) the adoption of selective mining would naturally make itself felt on the total gold production of the Rand. Then there can be little doubt that the opening and development of several good properties in the Far East Rand has also tended to improve matters on the whole, while several of the old established concerns have been concentrating their mining operations where better ore can be obtained.

It has already been pointed out that this higher gold recovery has not been represented by a higher proportionate mining profit; in fact, costs in some cases have so advanced that the higher recovery obtained has been wellnigh swallowed up by the higher costs of working. It was confidently expected last July that when the freight rates on coal to the gold mines were reduced on August 1, gold-mining costs would benefit to the extent of 2d. per ton milled. In August they advanced, as a matter of fact, and even today they are quite as high as before the reduced railway rates came into force. Still the working profits per ton milled have recovered somewhat of late, and now stand at 10s. per ton: the total working profit for September being £1,040,820.

The brightest spot in the Witwatersrand goldfields continues in the Far East Rand, for since the finely developed reef of the Main Reef series was cut in the Modder Deep shaft it has also been cut in several other places, showing practically the same content on the same property. In the neighboring New Modderfontein property the Main Reef in nearly as good state of development and as rich has been cut in a circular shaft situated some distance south of the present workings. This would seem to show that there is a good area of this well developed Main Reef. Then again on Rand Klipfontein driving on the reef has disclosed workable stretches, although the point at which it was cut in the shaft exposed reef of only 2 dwt. per ton assay value. At the State Mines the assays in the two shafts where the reef was cut were not very high, but it may be, as in the case of the Rand Klipfontein, further driving may result in the assays and working width being increased to something more approaching the average of the mines in the immediate district.

## NEW YORK

MARKET CONDITIONS.—THE BRADEN MINE.—DIVIDEND DISTRIBUTIONS.—SIBERIAN MINERALS.

The analyst of financial conditions at present prevailing in Eastern centres has never had to face conditions more complex or peculiar. The unanimity with which it is admitted that fundamental conditions are good, that is to say, that abundant harvests have placed a tremendous gain to the credit of material prosperity, admits of no dispute on this particular point. That in the face of such conditions there should have come upon Wall Street a disastrous slump bordering upon a panic seems a contradiction, the cause of which should be obvious, but it is not. That there has been some overextension in the flotation of high-income yielding industrial preferred stocks has been known in the Street for a long time. That these new shares, as yet unseasoned, should bear the brunt of bear attacks in such a slump is an effect rather than a cause. The various factors making for the present conditions form a medley of causes, and to distinguish the dominating factor is practically an impossibility. The dissolution of Union Pacific and Southern Pacific railway systems, as decreed by the Supreme Court of the United States, was something of a surprise to the rank and file of Wall Street, and the effect of the opinion has been to set the Street to calculating what would happen to the many similar combinations now operating in the railway and industrial world. It could hardly be considered possible, however, that this action alone could be held responsible for the drastic declines which have occurred during the past ten or fifteen days in the stock market and which have wiped nearly \$300,000,000 of market values off the slate.

The flotation of an Austro-Hungarian treasury loan in New York is probably of equal significance. The quieting of conditions in southeastern Europe has apparently been a rather simple matter, as diplomatic matters go, and probably more simple on its face than it is in reality. That the Eastern question, so long discussed as the skeleton in the closet of European diplomatic circles, the very rattle of whose bones has caused a chill in European capitals for a long time, is to be settled so simply is not credited by those who are inclined to look beneath the surface. There will be much done in the way of adjustment if the 'unspeakable Turk' is to be driven from Europe, and the Balkan states allowed to make progress as independent nations. The place which Turkey filled as a buffer state was an important one, and the Balkan difficulties must not by any means be considered settled. It may be that the possibilities and probabilities in this regard had more to do with the recent action of the stock market than might at first appear. A great deal has been made of the work being done by the Congressional committee which is investigating the so-called 'money trust.' Any new tariff legislation has always proved a disturbing factor, and underneath all of these various causes is the fact that the country has never paid the bill for the panic of 1907.

It is not surprising that, in the strained condition of the market, the favorable report issued by the Copper Producers' Association was without market effect. It was anticipated that an increase in copper surplus would be shown, estimates of such increase ranging from 10,000,000 to 20,000,000 lb. The Producers' figures show an added surplus of approximately nine and one-half million. This increase is a little more significant, however, when it is considered that production for the month was 134,000,000 as compared to 145,000,000 lb. produced in October. As compared with October consumption, domestic deliveries decreased from 84,000,000 to 69,000,000 lb., while exports increased from 47,000,000 to 55,000,000 lb., being a net decrease in consumption of approximately 6,000,000 lb. The unsettled conditions prevailing in the general market have made for stagnation in copper metal, and for the week the movement in copper has been a negligible quantity, though better business is looked for later in the month.

Among the copper-mining shares, Braden has taken a place as a star performer and is still being industriously

campaigning for distribution. In this regard it is pertinent to say that Braden carries, to a certain extent, the same handicap that is carried by Greene-Cananea, having a somewhat heavy capitalization in shares and bonds. Braden has a capitalization of \$14,000,000, of which \$8,000,000 is held in the treasury against the outstanding convertible bonds. Braden's bond issues are \$4,000,000 of 6% ten-year first-lien convertible bonds, \$1,000,000 of 7% five-year second-lien convertible bonds, and \$2,000,000 of 7% three-year convertible debentures. The company is also authorized to issue \$2,000,000 in coupon bonds. A copper production of 50,000,000 lb. is prophesied on the basis of present contemplated equipment, when the plant is fully installed. For the time being, Braden has rather usurped the stable honors from Chino, recently looked upon as the premier, of the Guggenheim string.

The Phelps-Dodge company has declared a final dividend for the year of 2½ and 3% extra, bringing total payment for the year up to \$15 per share. The British Columbia Copper Co. has also declared a regular quarterly dividend of 3%. It is expected that the British Columbia will proceed with the development of a part of the property which it has held under option in the Copper Mountain district and will in all probability put up a 1000-ton concentrating plant. After some months of experimenting with the Peterson process of zinc smelting, the Butte & Superior Copper Co. has decided to erect an ordinary zinc smelter.

## LONDON

FLotation PROCESSES.—TIN-MINING IN BOLIVIA.—THE TOLIMA SILVER-LEAD MINE.

The last two meetings of the Institution of Mining and Metallurgy have been notable for having presented an opportunity to the Minerals Separation company to give a public description and demonstration of its flotation process. The opportunity was provided by the reading of a paper by J. W. Ashcroft on the performance of this process at the Kyloe copper mine in New South Wales. H. L. Sulman, the consulting metallurgist, and Walter Broadbridge, the company's engineer, expatiated at great length upon the special claims of the owners of these patents, and upon their explanation of the principle upon which the process works. Mr. Broadbridge even went so far as to read a document, evidently prepared in the office of the Minerals Separation company, setting forth the views of high authorities as to their patents and process. Much that was said and done in the course of the proceedings was quite out of order. Many of the members present were inclined to waive decorum, because of the irregular opportunity provided for hearing the statement of the Minerals Separation case. This company, as is well known, has always been an apostle of secrecy. The reason for the sudden change is the approaching publication of Theodore Hoover's book on the 'Concentration of Ores by Flotation.' This book will be published at about the time this letter appears in print, and it promises to become one of the classics in metallurgical literature.

One of the largest companies operating tin mines in Bolivia is that founded by Avelino Aramayo. In 1906 the business was incorporated under English laws, under the name of the Aramayo Francke Mines. The interests are manifold, and the ramifications extensive. The properties consist of mines at Chorolque, Tasna, and Chocaya, a smelter at Quechisla, and a number of concentrating plants, the most modern of which, the Sala-Sala, was described in *The Mining Magazine* for March 1911. This plant was designed by Holmans. The district in which the properties are situated is in the southern part of Bolivia, between Potosi and Tupiza. The last yearly profit amounted to over £150,000, an increase of 50% over that of the previous year. Out of the profit, £31,000 was devoted to the redemption of debentures, and £119,318 was paid as dividend, being at the rate of 20%. The sale of tin concentrate during the year amounted to 4053 metric tons, which sold for £355,515, and of tungsten concentrate, 52 tons, bringing £11,625. Figures for the production of

bismuth are not given, as this market is a closed one. The alteration in the nature of the ore worked during the past few years is noteworthy. Originally the tin ore from the outcrops was rich, and ore containing 6% was thrown on the dump. Owing to the exhaustion of the surface ores it has been necessary to provide modern concentrating plant for the treatment of the lower-grade ores, and much money has been spent with this object in view. In 1909 the tonnage of ore treated was 17,522, averaging no less than 19% cassiterite; in 1910, the tonnage was 25,882, averaging 14½%; in 1911, the figures were 36,903 tons, averaging 10½%; and during 1912 up to date, 41,436 tons has been milled averaging 9.9%. The Santa Barbara dumps, averaging 6%, have been exhausted, and other dumps averaging 3% are now to be treated. Hydro-electric plants are being supplied for power and drilling purposes; owing to the high altitude at Chorolque, 14,000 to 16,000 ft. above the sea, the use of compressed air is avoided. A smelter has been erected at Quechisla for the purpose of producing copper matte; this is expected to be in commission shortly. The mines also produce some silver.

Now that the Panama canal is approaching completion, Americans are widening their interest in South American doings, and are receptive of information relating to mining operations there. One of the oldest English ventures in Colombia is the Tolima Mining company, which was formed in 1871 to acquire the Frias silver-lead mine in the Tolima district. In early days large profits were made. Later, in 1903 and 1909, it became necessary to reconstruct and so provide further funds. Last year the mine was once more placed on a profitable basis, and the report for the year ended June 30 last shows that the improvement has continued, for not only have the debentures been retired, but dividends have been paid to the shareholders. The amount of ore raised was 15,645 tons, from which 1291 tons of concentrate was produced, estimated to contain 649,844 oz. silver, or 505 oz. per ton. The amount of concentrate shipped abroad during the year was 1280 tons. The sum of £73,116 appears in the mining account as credit for ore shipped, and against this is an item of £16,445 for freight and smelters' charges. The profit for the year was £19,132, out of which £10,208 was devoted to the redemption of the debentures, and £5000 distributed as dividend, being at the rate of 5%. Developments have been encouraging, and the ore reserve is sufficient to keep the mill going for nearly two years. The increased funds in hand will make it possible to continue development work. The directors are considering purchase of a neighboring gold-silver mine.

Recently some particulars were given of the new group formed by F. A. Govett, H. C. Hoover, A. Chester Beatty, and others for examining and floating mines in all parts of the world, the corporate company being at present called the Lake View & Oroya Exploration. Another new group, centring round the Camp Bird and A. M. Grenfell, of the firm of Chaplin, Milne, Grenfell & Co., is also worthy of attention. Like so many British institutions, both of these businesses have been gradual growths out of other things. Mr. Grenfell's new venture is the outcome of the Camp Bird. Two years ago, when this famous Colorado mine showed signs of exhaustion, the Santa Gertrudis silver mine at Pachuca was purchased, and now that the Camp Bird is actually on its last legs, further properties are to be sought. In fact, negotiations are already pending for the acquisition of another Mexican mine, the name of which is at present kept secret. Six months ago the Camp Bird guaranteed the interest on a new issue of debentures created by the Messina copper mine in the Transvaal, which has been developed under the wing of Chaplin, Milne, Grenfell & Co. These are the beginnings of an important mining business in the city of London, which, having been founded on genuine mining and not on spectacular prospectuses, promises to become a sound and prosperous institution. Mr. Grenfell's report at the annual meeting of the Camp Bird company was given at some length last week. Details of the work at Santa Gertrudis and Messina will be of interest.

## BOSTON

RYAN AND COLE.—LAWSON AND REID.

Fresh evidence is accumulating to support the idea that Thomas F. Cole and John D. Ryan are 'going it alone' in the copper world after having acted together for several years in the Cole-Ryan syndicate. Mr. Ryan has shown himself to be a big constructive figure in harmonizing discordant elements in the copper industry and in bringing into it some of our leading financiers, notably W. E. Corey, late president of United States Steel Corporation, and more recently Daniel G. Reid, of the Rock Island and Lehigh Valley lines, American Can Company, and the new Tobacco Products Corporation, a \$50,000,000 company. Mr. Ryan joined Reid, Frick, and others in the formation of this mammoth tobacco company and now it is announced that Mr. Reid has taken on a lot of Inspiration Copper stock, and may later on become a member of the Amalgamated board. Reid, notwithstanding he has been one of the most prominent and active speculators in Wall Street, had never been identified with the copper industry until Mr. Ryan got him interested. As Ryan represents Standard Oil and the Rockerfellers, and as Reid has associated with him First National Bank interests, Frick, and the old guard generally of United States Steel, it is easy to see that some very formidable new interests are being brought into the copper trade through the initiative of Mr. Ryan. Mr. Cole, former active associate of Mr. Ryan, is showing scarcely less initiative on his own account in the copper industry. When Cole was the general manager for the Oliver Iron Mining Co., a subsidiary of the United States Steel Corporation, before the development of Calumet & Arizona, it took hard work on the part of his brother-in-law, James Hoatson, of Michigan, to get him to put some money into the deal. Hoatson finally succeeded and the rich Calumet & Arizona developed, notwithstanding it had formerly been considered rank heresy to suggest that there was in Bisbee any commercial mineral ground lying outside of the Copper Queen estate. Now Mr. Hoatson is resigning from the presidency of North Butte and Mr. Cole taking his place. Mr. Cole is also cutting a very wide swath in optioning and developing mineral ground in the northern end of Butte, beyond North Butte and Butte & Superior, an enterprise with which Mr. Ryan disclaims connection. Mr. Cole is also heavily interested in the Keweenaw consolidation plan to prospect and exploit the old Ashbed lode on a scale of sufficient magnitude to make it a profitable enterprise, after having lain dormant so long. Now it is believed in Boston that Mr. Cole has his mind upon making Giroux the nucleus of another big copper producer in Ely, which means that the Gunn-Thompson Coppermines estate and perhaps other ground will eventually be merged with Giroux. Mr. Cole has expressed the opinion that the Ely district is too large a territory and too rich to be monopolized indefinitely by any one company. This leads to the inference that he proposes to take a much bigger hand in Ely than heretofore. Doubtless his greatly increased interest in Butte, along with his accession to the presidency of North Butte, is inspired by a similar idea. He presumably thinks that Butte is too large a mineral district to be monopolized by one interest. His movements in Butte and Ely will be watched with great interest, as it is believed that he is on his mettle and will make a supreme effort to get a strong footing in both districts under his personal leadership. The same statement will probably apply to his operations in exploiting the Ashbed lode.

It is claimed that Thomas W. Lawson has been giving battle to Daniel G. Reid in the market recently, Reid taking the bull and Lawson the bear end of the argument. This battle, which followed the Supreme Court decision ordering the segregation of Union Pacific and Southern Pacific, is said to have little or nothing to do with that decision, but was simply a trial of market strength and ability between two prominent operators. The old rumor that somebody was negotiating for the Bay State Gas blanket charter was revived and it was stated that Lawson was piling up big profits on the bear side of the market for the Bay State

Gas treasury. Then it was stated that Reid had rallied powerful banking support and routed Lawson and the bear crowd, taking from them the profits they had been credited with. Meanwhile market interests here are waiting for news from Trinity and First National.

### KALGOORLIE, WESTERN AUSTRALIA

GREAT FINGALL REVIVES.—THE LABOR SITUATION.—DEVELOPMENT AT GREAT VICTORIA.

The Great Fingall mine at Day Dawn looks as if it would have a new lease of life. This mine started as a producer in 1895, and by the end of 1898 had produced \$375,000 from 30,000 tons, when the first lens of ore cut out at a vertical depth of 150 ft. The mine was within an ace of being abandoned, but fresh capital was raised in 1899, and a fresh lens cut at a depth of 400 ft., which continued to 1500 ft. vertical, when it also pinched out. From 1899 to the present time this lens has produced \$32,869,900 from 1,773,200 tons, yielding \$8,671,800 in dividends. Winzes put down below the 18th level show that the ore persists. A hoist is being installed at the 13th level, 900 ft. north of the main shaft, where a winze has been sunk to the 18th level. A chamber to accommodate the outfit has been cut 40 ft. high. The reason for this is that the gold shoot has pitched to the north, completely away from the main shaft, rendering it useless for deeper development.

The manager of the Kalgurli, whose financial year ends on July 31, estimated his ore reserves on that date at 250,000 tons worth \$10 per ton, against 430,000 tons worth \$14.25 three years ago on July 31, 1909. During the past three years 375,000 tons has been treated, returning \$43,999,800, or \$11.70 per ton, or \$2.55 per ton under the estimate. So little ore has been developed in the last three levels that ore reserves have been dissipated at the rate of 60,000 tons per year. The Kalgurli lode is a huge lens 300 ft. long by 240 ft. wide at its extremes, and it is apparently tapering off vertically as it has done horizontally. The company holds 18 acres, much of which has not been thoroughly prospected.

Richard Hamilton, manager of the Great Boulder Proprietary, has just withdrawn his staff of samplers from the Great Victoria at Nevoria, after being there for 10 to 11 weeks. During this time not only the workings at the 60 and 300-ft. levels have been sampled, but trenches have been cut across the lode at intervals along the surface for a considerable distance. The cross-cut at the 300-ft. level has been extended a total distance of 140 ft. without reaching the hanging wall. The value of the ore from 100 to 125 ft. is \$12.50, and the remaining 125 ft. of the cross-cut assays \$6.50. Mr. Hamilton has made an agreement to work the mine under option for the next 12 months, when a lot of shaft-sinking and other development work will be undertaken to thoroughly test the property. Most of this work will be done by contract. In the meantime the owners will re-start the mill, as they have connected it with a dam three-quarters of a mile away, where there is about two months' supply of water for the mill. Mr. Hamilton is acting on behalf of the Great Boulder Proprietary, of which the principal lode has passed into the Golden Horse-Shoe somewhere between 2500 and 2600 ft. If the deal comes off the life of the Boulder will be indefinitely prolonged.

The Victorians at Ora Banda, owned by the Associated Northern, ran two mills and two Ridgway vacuum-filters during September, and treated 5007 tons, yielding \$26,000 and a profit of \$11,200. This was converted into a loss of \$4100, owing to \$15,300 being expended on extra plant. Owing to the salt water used for treatment, the filter-cloths became coated, and the press capacity was only 2500 instead of the 4000 tons anticipated. It is probable that two more filter-presses will have to be added before 12,000 tons per month can be handled with \$30,000 profit.

Harry P. Woodward, the only Government geologist in Western Australia who risks a prophecy, was invited by Chesson & Heydon to advise where to look for the lode in the Hidden Treasure mine at Cue, which had been completely cut off. On Mr. Woodward's advice, a cross-cut was started eastward below the bar and the lode promptly found, assay-

ing \$40 per ton. The price paid for the mine a few months ago was \$175,000, and the owners were much chagrined when the lode suddenly disappeared. Needless to say, Mr. Woodward's reputation has been greatly enhanced by this incident, and it may yet lead to operations being renewed on Fraser's mine at Southern Cross, from which \$3,622,500 was won from 325,600 tons, all from above the 300-ft. level. This mine is lying idle, although Mr. Woodward strongly urged the Government to thoroughly test it at depth by boring, and predicted a successful issue.

### FAIRBANKS, ALASKA

NEW MILLS. HUDSON DISCOVERY.—THE PRIDE OF THE DISTRICT.

The month of November will see the completion of four of the small mills brought in before the close of navigation and the production from these during the winter should materially swell the output of the Fairbanks district for the year. Of those four plants, the 5-stamp Joshua Hendy mill belonging to the Pioneer Mining Co. on Chatham creek, has already been operating several days. The Hudson Bros. 2-stamp Nissen mill has just been completed, as has also the 2-stamp Hendy mill of the Rexall mine. Capt. Spalding's 2-stamp Hendy mill will also be crushing before December.

While the working shaft of the Hudson mine is not quite ready to supply ore to the mill, it is only a question of time till the orebodies opened up in the prospect shaft will be cut. The installation of the mill this season will make a saving of many months in opening up the mine as it is now ready to handle a fair tonnage and give material returns toward development expenses. Not far from the Hudson vein, William Maloney has found a fine vein of good ore. While the claims have been staked for several years and considerable work done on them it was only recently that the main vein was found. While the vein has thrown many valuable stringers to the surface the main orebody was found only by following stringers and gouge down a distance of 30 ft. At that place the vein is from 2 to 3 ft. wide, with well defined walls and excellent gold content. Two samples taken across the vein showed assays of \$80 to \$100 per ton.

Another promising display has been made at the head of Big Eldorado by Al Goodwin. Good assays were obtained from surface samples and it is understood that a lease has been taken recently. During the summer and fall, the little 3-stamp mill belonging to Capt. Spalding of the Reliance Mining Co., has pounded out about \$15,000. With stamps only weighing 250 lb. and the mill operating only a few hours a day, the ore has averaged close to \$400 a ton to produce this output. The new 2-stamp, 100-lb. Hendy mill will be ready this month and with plenty of ore available the production should leap to over \$1000 per month. The new mill is placed where an abundant supply of water is available. A quarter interest in this property was recently bought by Dave Cascaden and Harry St. George for \$15,000. Two leases have been let on adjoining claims and in one of these considerable ore that should average over \$100 per ton has already been blocked out.

The 'Pride of the District,' the common appellation of the Rhoads Hall mine, on Bedrock creek, is sending in its regular clean-up. Cost and production figures from the property would make very interesting reading, but as yet have been denied the public. The first level below the main adit is now being opened up while the winze is still being sunk. The electric sinking plant has proved a big success. A Frue vanner bought from the Rainbow plant is being added to the mill equipment. The Tolovana 2-stamp Nissen mill has just shut down for a short while till the development work in the new winze can make available some of the high-grade ore found in the bottom levels. The operation of the mill is successful to date, the ore being amenable to amalgamation. The tailing content is unusually low, seldom running over \$1 per ton. The clean-up netted over \$2000.

## General Mining News

### ALASKA

#### FAIRBANKS

It is stated that, for \$40,000 cash, C. Fornander, one of the discoverers of the Ruby district, sold out his interests on November 15, making a total of \$100,000 which he has netted from all his claims. On Long creek, gravel has been proved for over three miles.

#### JUNEAU

Early in December the six Lemon creek lode claims and placers, and the Hallum properties embracing 13 quartz claims on the slope of Mt. Juneau, were consolidated by E. R. Chapman, of New York, and G. R. Noble. The Lemon creek properties include a water right capable of furnishing 1150 hp. throughout the year. This deal makes four large properties under development in the Silver Bow basin, including the Perseverance and Alaska Juneau, and Juneau promises to be a large mining centre.

#### VALDEZ

The Fidalgo-Alaska Copper properties are opening well, and 14% ore is being mined. A raise has been driven 127 ft. on the ore. Recently a shipment of 250 tons of ore was ready for the bins, when a portion of the new wharf collapsed, due to the torredos having eaten the piling put in 18 months ago. At the Ramsay-Rutherford, a second vein has been cut 55 ft. from the first one opened. The former was cut at a depth of 120 ft., and is 20 in. wide, with good ore. Work continues during the winter.

### ARIZONA

#### COCHISE COUNTY

At the Copper Queen mines changes in mining methods are being made, in that 'slicing' will be used in breaking ore. At the Czar mine, circular concrete raises are to be put in starting from the 400-ft. level, and extending to the 200-ft. level. Through these ore will be taken to the 400-ft. level, and then trammed to the Sacramento shaft for hoisting.

Good progress is being made with the new smelter of the Calumet & Arizona at Douglas. The stack connected with the reverberatory furnaces and converters is 380 ft. high, and that with the McDougall roasting-furnaces is 300 ft. Both have been painted. Brickwork on three reverberatories is being built, while on the blast-furnace dust-chamber building the copper roofing is three parts finished.

#### GILA COUNTY

Production of the Old Dominion during November was 2,758,000 lb. of copper, against 2,523,000 in October.

#### YAVAPAI COUNTY

(Special Correspondence.)—Work on the Bonnie group of claims, which are situated a few miles east of Prescott, is showing some excellent ore. It will be remembered that splendid ore was discovered here several years ago, but the very richness of the ore proved its undoing, for the owners of the property could not agree as to working plans, so the mine has been idle until recently. The ore in the new shaft shows high content in gold and silver, and also a good percentage of copper. The copper content is getting higher as the vein is developed.

G. W. Hull of Jerome has two carloads of high-grade ore from the Cleopatra ready to ship to the smelter at El Paso. The Arkansas & Arizona Co. at Jerome, is making a splendid showing, and its stock is practically off the market, local parties holding most of it. The Verde Valley railroad is completed to the new smelter site at Clarkdale.

Prescott, December 9.

#### YUMA COUNTY

The mines and smelter of the Swansea Con. Gold & Copper Mining Co., are now under new management, and within the past month, the smelter has been working successfully, contrasted with previous trouble. One of the blowers was cut out, and blast pressure reduced from 25 to 10 oz. Pro-

duction is now at an average rate of 11½ tons daily of copper, 200 tons of ore coming from the Swansea and 100 from the Blue Bell mines per day.

At the mine, development is confined to work at the 300 and 400-ft. levels at No. 5 shaft. Orebodies here are nearly 50 ft. wide, and occur as lenses. Average copper content is about 4%. The ore is soft, and considerable trouble is experienced in holding it up, so a new system of mining is to be tried, involving the caving method. C. Clere is general manager, W. H. Seamon smelter superintendent, and H. D. Hughes, mine superintendent.

### CALIFORNIA

#### BUTTE COUNTY

Timber companies are refusing to allow prospecting on their lands in the Lumpkin district, and mining is thereby retarded. Twelve men are working at the Triumph mine, where an adit is in 450 ft., and 20 tons of ore is being crushed daily.

#### CALAVERAS COUNTY

The Calaveras Copper Co., operating mines at Copperopolis, is planning to construct an electric railroad, probably between Milton and Copperopolis, a distance of 16 miles, and costing about \$200,000. During November 22 cars of ore were shipped to the Kennett smelter, which gave net returns of \$23,063.

#### KERN COUNTY

(Special Correspondence.)—Electric power will be available for the mines and mills of the Rand district early in the new year. This is expected to promote the treatment of the large deposits of low-grade quartz exposed on several properties. Development at the King Solomon has been satisfactory. The raise from the 250-ft. level has intersected an ore-shoot said to assay over \$80 per ton. A recent shipment of 66 tons yielded \$4200. Rich consignments have been recently sent out by Teagle-Lamberson, Cook & Lipps, and other lessees. Much of this averaged about \$50 per ton. A half interest in the property has been purchased from E. Shipsey by C. J. Lehman, of Los Angeles. Driving and stoping is progressing from the 175, 235, and 300-ft. levels of the Good Hope claim of the Consolidated Mines Co. Good ore is reported at all three points. The company is doing some work at other points on its group. Los Angeles people are largely interested. Several small properties in the Randsburg and Stringer districts are being developed.

Randsburg, December 12.

Oil lands covering 29,541 acres in the Buena Vista hills

LAKE VIEW WELL.

district have been withdrawn from entry by the U. S. Government, making a total of 67,000 acres reserved for the navy. This is the result of investigations by the U. S. Geological Survey.

#### LOS ANGELES COUNTY

(Special Correspondence.)—The annual election of officers and directors of the Los Angeles Chamber of Mines and Oil was held on December 12, and the following were chosen: president, S. E. Vermilyea; chairman of committee on library and publications, F. J. H. Merrill;

on membership, E. A. Montgomery; on mineral and geological exhibit, J. N. Nevius; on mines and mining, L. W. Powell; on petroleum, W. W. Orcutt; on reports and certificates, H. D. Mackinnon. Mr. Nevius attended the California Miners' convention at San Francisco, as official delegate from the Chamber. He has gone to Kennett, to investigate for the Smelter Smoke Committee of the Chamber, the bag-house system at the Mammoth plant. This is to get specific information for proposed legislation to be discussed at next session of the State Legislature. The committee is of the opinion that there is equitable ground upon which farmers and smeltermen can agree.

Los Angeles, December 12.

The American Potash Co., recently organized with a capital of \$1,500,000, will erect a plant near Los Angeles, and manufacture potash and by-products from kelp. The annual output will be valued at \$1,000,000.

#### PLUMAS COUNTY

A discovery of importance is reported from Belden, in an old channel on the North Fork, one mile above the junction with the Feather, and is owned by J. Nevill, of Clio, California. The property is under bond to the West Sacramento Mining Co. Gold occurs in a deposit 20 ft. wide and from 12 to 42 in. thick.

The Oro Fino, known as the Hewitt mine, on Hopkins creek, is crushing with five stamps; and the owners are getting satisfactory returns. At the Kelly-Reed claims, on Winter creek, a shaft is down 75 ft., and a 3-stamp mill is ready for work in the spring. Snow has interfered with work at several claims.

#### SHASTA COUNTY

The Shasta County Farmers' Protective Association has elected a new set of officers, and plan to take action against the Mammoth smelter at Kennett, where, with the adjoining mine, 900 men are employed. The Mammoth people will contest any case brought against them. Repairs to the Mammoth bag-house and other parts of the plant have been finished, and three furnaces were blown in on December 11, eight days after the accident. The Union Iron Works of San Francisco supplied the spare parts, which included two line shafts weighing 4000 lb. each, and a pulley weighing 2500 lb. At the Mt. Shasta mine, a few miles north of Redding, it is intended to start extensive work early next year and employ over 100 men.

#### SIERRA COUNTY

A fair-sized gravel deposit has been uncovered at the White Bear claim in New York adit, and the gravel is similar to that known as the Belcher channel, worked by the White Bear company. Gravel containing gold has also been found in a drift being driven in the Mountain House group of claims, which is under bond to Shaw brothers of San Francisco. The main adit has been driven into the gravel 60 ft., and a cross-cut 30 ft., all in gravel. At the Bunker Hill gravel mine it is intended to clean out and retimber the old adit, which was driven several years ago, and probably extend it to find bedrock.

The Haskell Peak mine is on the border of this and Plumas counties; Marysville, Nevada City, and Oroville men are interested. An adit has been driven 200 ft., and last week gravel was entered which pans well. This property is at an altitude of 6300 ft., and much snow has fallen. J. J. Snyder is in charge.

### COLORADO

#### CLEAR CREEK COUNTY

(Special Correspondence.) P. Knaub, of Denver, has taken a lease on the Tobin mine in East Argentine. It is stated that 40 men will be employed within 60 days. Shipments will be started at once. A Norwalk compressor has just been installed at the Smuggler mine on Brown mountain. The machinery will be electrically driven. Pilz & Co., leasing on the McClellan mine on Leavenworth mountain, have started carload shipments of smelting ore. The product is being consigned to the Salida smelter, and is worth \$30 per ton in silver and lead. The Geneva

adit on Alpine mountain has been driven 200 ft. In the breast a mixed body of ore 10 in. wide is showing which will yield over \$40 per ton. Large development is planned by the Onondaga Mining Co., controlling the Comet and Ruler groups of mines on Griffith mountain. It is proposed to drive an adit 4000 ft. to intersect the entire vein system. C. H. Rowland, of Syracuse, New York, is financing the project. The Crist property, on Democrat, will soon be entered among the list of shippers. The adit has been driven 285 ft. and in the breast there is showing an orebody of quartz that is from 10 to 16 in. wide. A. Robert, leasing on the Virginia City, situated on Lincoln mountain, has started shipments of high-grade smelting ore. Returns of \$70 per ton in gold and silver are being realized.

Georgetown, December 9.

#### GILPIN COUNTY

Several months ago a drift was driven on the Burroughs vein, in the Phoenix-Burroughs group on Quartz hill, from the Newhouse tunnel at a depth of 1600 ft., a distance of 300 ft., under the shaft and old workings on that and the Kansas vein; and a diamond-drill hole bored through the country to tap the immense quantity of water the mines held. Drainage from this was slow, so another hole was drilled, and cut an ironstone vein carrying good metal contents, which was also cut in No. 1 hole, which was extended later on. Both holes are draining the water at a rate of 24 in. daily, the pressure being 400 lb. per sq. in. This drainage scheme will mean a great deal to the district. R. Sayre and F. Berger have been largely responsible for this work.

#### LAKE COUNTY (LEADVILLE)

From the portal of the Yak tunnel, toward the head of California gulch, a good deal of work is being done, and the monthly output of iron, and sulphides and carbonate of zinc is considerable. Lessees are responsible for most of the activity shown here. From the Stars Con. properties, on Carbonate hill, the monthly production is over 4000 tons of mixed ore. The Leadville Light & Power Co. is erecting a new power line in the Kokomo district. About three miles of the line will be used to supply power to the Boston Con. and other small properties. The mill situation in the district is looking better. The Leadville district mill has changed hands, and improvements have been made. It consists of crushers, tables, and magnetic separators, with a 100-ton capacity. The Yak mill will soon be able to treat over 200 tons per day.

#### OURAY COUNTY

Shipments of concentrate from the Ouray station of the D. & R. G. railroad for November totaled 71 cars, containing about 1600 tons. The Revenue mine and mill has been shut down on account of shortage of water. About 60 men were employed. The company expects to start again early in March. At the Barstow, a raise will be driven from No. 1 adit to prospect for new orebodies, and the shaft will be sunk 100 ft. Thirty men are employed.

#### SAN JUAN COUNTY

J. T. Barnett and G. T. Bradley are arranging to build a concentrating and zinc separating plant at Silverton. It will be erected on the site of the old T. F. Walsh smelter. The initial capacity will be 200 tons per day, and it will separate the concentrate of other mills. A complete cyanide plant will be operated with the other treatment. An 80-hp. boiler and 75-hp. engine, formerly used at the Pride of the West mill, were shipped from Howardsville to Aztec, where they will be used for an electric-light plant.

#### SAN MIGUEL COUNTY

The Lewis mine has been closed until next spring on account of shortage of water, and 20 men were thrown out of work. Heavy snowstorms have affected the water-supply. About 15 men will be kept on development through the winter and the main shaft deepened.

The Tomboy mill worked 28 days in November, and treated 10,000 tons of ore worth \$31,500, with \$54,500 from

concentrate shipped, making a total of \$86,000. The profit was \$40,000, and \$5212 was spent on permanent improvements.

#### TELLER COUNTY (CRIPPLE CREEK)

The U. S. Supreme Court has handed down a decision which affirms the decision of the circuit court for Colorado, which granted the Doctor-Jack Pot possession of the Lucky Corner claim, which the Work company asserted was obtained by fraudulent means, and that there was no discovery vein, and therefore there could be no extralateral rights. The outlook for the Joe Dandy mine is said to be good; 20 cars of ore being shipped in November from the 500-ft. level.

### IDAHO

#### LEMHI COUNTY

A company with \$100,000 capital has been organized by O. P. Zortman, of Gibbonsville, to operate a group of 22 claims, covering about 450 acres, and a millsite. The lower adit on the Twin Brothers section is in 1226 ft., with a depth of 800 ft. About 15 veins from 12 to 48 in. wide have been cut, which carry pyrite, and the ore is amenable to amalgamation and cyanide treatment. A gasoline engine and machine-drill will be installed, and a 500-ft. cross-cut driven.

#### SHOSHONE COUNTY

The Federal Mining Co. is negotiating for the control of the Star Mining Co., whose mine adjoins the Morning at Mullan. The former company has been treating ore from the Star mine for several months. Considerable development has been done, and the price offered is said to be over \$250,000.

### MISSOURI

#### JASPER COUNTY

The continued production from the Webb City district, averaging more than 2000 tons per week, shows the importance of thin sheet ore mining as a factor in the development of the industry. Although the average sheet ground mined in that district will yield no more than 3%

PROSPECT SHAFT, JOPLIN.

blende and galena, often running down to less than 2%, compared with a yield of 7 to 15% in the soft-ground areas of the district, Webb City has an output of concentrate far in excess of Joplin, from which place the bulk of the ore comes from soft or disseminated ground.

Prior to a few years ago the soft-ground mines produced by far the greatest tonnage of concentrate, but as the sheet-ore districts were gradually extended, vast new areas were opened and concentrating plants of large daily capacity were constructed. Although these mills are forced to handle a much greater tonnage in order to produce as great a volume of concentrate as the mills in the soft-ground districts, their aggregate capacity is so much greater that the quantity of concentrate likewise is greater.

With stronger prices the output of the sheet-ore districts increases faster than does the production from the soft-ground areas, and a decline in prices causes a sharp fall-

ing off in sheet-ground production. Should prices drop below a certain level, \$40 or \$45 for example, the chances are that the volume of soft-ground ore would overbalance that of the thinner regions, this condition being due to the smaller expense of operating the soft-ground mines.

#### ST. FRANCIS COUNTY

The St. Joseph Lead Co., Bonne Terre, is adding to its power-plant equipment at the Leadwood mines a large 1000-kw. alternating-current generator. In the power-plant of the Bonne Terre mines a new 1250-kva. Curtis turbo-generator is being added to the equipment, and the installation made by the General Electric Co., the builder of both machines.

### MONTANA

Articles of incorporation were filed at Trenton, New Jersey, by the Butte Electric & Power Co., Montana Power Co., Madison River Power Co., Billings & Eastern Montana Power Co., and the Missouri River Electric & Power Co., which have a combined capital of \$14,000,000. The new company, under the name of the Montana Power Co., has an authorized capital of \$100,000,000.

#### CASCADE COUNTY

(Special Correspondence.)—With the death of O. C. Mortson on December 11, the Great Falls public library has come into possession of a fine and extensive collection of Montana minerals, ores, rocks, and fossils. Mr. Mortson had been making this collection since his first arrival in Montana in 1872, and the palentological section of it was particularly complete, containing much material from undescribed localities.

Great Falls, December 14.

#### DEER LODGE COUNTY

(Special Correspondence.)—The concentrator at Anaconda has been remodeled and enlarged so that more water is required. As the present big ditch consumes the entire surface of Warm Springs creek during the low season, the company is planning to increase the supply in other ways. A shaft is being sunk to bedrock in the creek bottom below the intake of the flume, and an electric pump will be installed to deliver the underground flow to the flume.

The Butte & Georgetown Mining & Milling Co. has interested French capitalists in its dredging ground near Georgetown. A French mining engineer, Maurice de la Bathie, is to examine the property with a view to the installation of a modern electrically-operated dredge. It is stated that the gravel will yield \$1 per cubic yard.

Anaconda, December 14.

#### LEWIS AND CLARK COUNTY

(Special Correspondence.)—Montana citizens are making strenuous efforts to preserve the United States assay office at Helena. Congress, however, has failed to make the usual appropriations for the offices at Helena, Boise, and Salt Lake, so that their discontinuance seems certain.

Helena, December 14.

#### MADISON COUNTY

(Special Correspondence.)—The Butte-Virginia Mining & Milling Co. has been operating under lease the Grant mill near Virginia City. During the past few months there has accumulated below the mill a large dump of tailing which assays about \$10 per ton in gold, and the company has been remodeling the mill for re-treatment.

Virginia City, December 14.

T. Tonich and associates have been inspecting the Virginia City district. Several improvements have been made at the Grant mill which will enable a higher saving from the ore of the Bell mine. As a result of a tour of the district, a syndicate is being formed in Butte to erect a 100-stamp mill, and construction will be started in the spring. In this custom plant, low-grade ores will be profitably handled.

#### SILVERBOW COUNTY

At the Butte & Superior the new hoist and second section of the concentrating plant have been started. The former is capable of lifting 7-ton skips from 3000-ft.

depth. The skip-changing device enables cages to be substituted in quick time. It is expected that 100 tons per day will be treated when all is in proper order. The Butte Central mill is treating 475 tons of ore per day, and the second section is about complete, which will mean over 900 tons treated by the whole plant. The opening of a rich orebody on the 2600-ft. level of the Adirondack vein of the North Butte has added considerably to its reserves. It is 15 ft. wide, of hornite and copper glance, averaging 6 per cent.

After several months' delay, the work of electrifying the Butte, Anaconda & Pacific railway has been resumed. The delay was due to union troubles over wages, the scale obtained by electricians from the Anaconda union not being acceptable to those from the Butte union. Other labor organizations attempted to bring about a settlement and finally the local union accepted the offer of the railway company to pay \$4.75 for an eight-hour day, which covers all time between leaving the shop and returning.

## NEVADA

### ELKO COUNTY

At the Mizpah-Dolly Varden district, 72 miles north of Ely, prospects are said to be fairly good. The mineralized area is about  $\frac{1}{4}$  mile wide by 14 miles long, and veins are in porphyry, containing about 5% copper, and gold and silver. A Keystone drill is working on the Cable group, in the south end of the district, and is in porphyry, while another drill is to test the Moore & McAuley group near the centre portion.

### ESMERALDA COUNTY

At Klondyke, lessees are mining good ore from the various properties. At the Golden, Manning & Tyler have six men breaking out ore which assays from \$14.20 to \$112 per ton. At Mexican gulch, about two miles south, Woodruff & Randolph are sinking two shafts in low-grade ore. A 25-hp. gasoline hoist is working at the Marietta claim, and two shifts are at work sinking. Lee and associates have teams hauling ore to the Klondyke siding. The town of Golden has been laid out, and streets are being cleared; three stores and restaurants are being built, besides other structures.

During November the Horn Silver mine produced 4095 tons of ore carrying zinc and lead, from the 300, 500, 700, and 900-ft. levels. Several other claims in the district are doing considerable work.

Negotiations have been completed whereby the Merger company acquires the use, jointly with the Jumbo Extension company, of the main shaft of the Polverde mine and also of its plant and other equipment. This will enable the Velvet claim to be developed, as it has been known that the Jumbo Extension, on the 900-ft. level, had opened a rich ore-shoot to the boundary of the Velvet, and is developing this ore on the 1012-ft. level also.

In a circular to shareholders the Goldfield Consolidated company states that dividends to date total \$23,839,067. Dividends of 30c. per share require quarterly net earnings of \$1,067,744, and of late they have been less than this amount. Prior to October 31, 1912, cash on hand, etc., totaled \$1,000,000, but the last dividend made a reduction of this, and the directors believe it undesirable to further reduce the company's cash reserves, and dividends will be only paid as earned.

### HUMBOLDT COUNTY

Great interest is being taken in prospecting in Rochester canyon, and many claims are being opened, while lessees are taking out ore. The *National Miner* of December 13 gives a long and booming account of work being done and what has been done in this district.

At the Seven Troughs Coalition mine a 24-in. vein is being opened on No. 10 level, and averages \$125 per ton. Bullion worth \$12,000 was shipped on December 4, the result of a six-days mill-run.

### NYE COUNTY

The Tonopah Merger has shipped over 550 tons of ore

to date, and development is satisfactory. From the November run the Montana shipped 3678 lb. of bullion and 32 tons of concentrate, from the treatment of 3997 tons of ore. Extraction has been up to 93.8% for a week's average. At the MacNamara the amount crushed has been increased to 8 tons per stamp by putting coarser screens on the mortars. The November output was valued at about \$20,000. To the end of October, Tonopah mines have produced \$56,007,587 in bullion, and paid \$14,778,559 in dividends. Average value from May to November was \$18.61 per ton. During the week ended December 14 the mines yielded \$211,908 from 11,297 tons of ore.

At Manhattan the new cyanide plant at the Brady mill is about ready for work, making three 10-stamp mills and cyanide plants in operation, and a fourth is being erected at the Big Four. On the 100-ft. level, the Big Four company has opened 12 to 18 in. of ore worth \$200 per ton.

### STOREY COUNTY

The Mexican company shipped eight bars of bullion, valued at \$20,000, during the week ended December 14, and treated 579 tons of ore worth \$15,575, with 92.5% extraction. Good headway has been made at the Monte Cristo and Keyes properties. At 2300 ft. in the Consolidated Virginia the east cross-cut is out 206 ft. in formation. The Ophir cyanide plant shipped to the Selby smelter bullion worth \$2400. At the Sierra Nevada the northeast drift on the 2500-ft. level advanced 33 ft. on the hanging wall, which carries a little quartz. From the Crown Point 580 mine-cars of ore, worth \$4500, was extracted from the 1480-ft. level, and the Yellow Jacket saved 320 cars, worth \$1500, from the adit raise.

### WHITE PINE COUNTY

At a depth of 175 ft. from the surface, rich copper ore has been cut in the Sunday shaft of the Ely Calumet. At the claims of J. D. Tilford and others on Snake creek, near Baker, in the extreme eastern portion of this county, about 50 tons of tungsten ore is on the dump, worth from 15 to 60% tungstic acid. A 42-in. vein has been opened in two shafts and an adit. The ore will be hand sorted to bring the average to 40%, which will return \$4 per unit at Newhouse, Utah. In the spring a small mill with concentrating tables may be built.

## SOUTH DAKOTA

### LAWRENCE COUNTY

(Special Correspondence).—The Kaleva Mining Co. has been incorporated, and organized by the election of the fol-

WASP NO. 2 MILL, A SUCCESSFUL BLACK HILLS MINE.

lowing directors: C. J. Pease, president; J. B. Tario, vice-president; W. Richards, secretary-treasurer; J. W. Peterson and J. Savage. All are residents of Lead. The company has not announced the property that it will take over, as a number are under consideration.

The Cleopatra mine, on Squaw creek, was recently sold at sheriff's sale for \$23,000, being bid in by bondholders. The new owners will organize the company and open the mine. The property is equipped with an old fashioned

cyanide plant, which will have to be remodeled before it will be suitable for use. It was one of the first built in the Black Hills.

Construction is being rapidly completed at the Bismarck, all of the machinery having been delivered, and nearly all of it is in place. The electric motors have been ordered and as soon as they are delivered, and installed, the plant will be ready to begin operating, which should be soon after January 1. The North Homestake property has just been examined by J. H. Farell, who spent several weeks at the property, and made a thorough investigation. Preparatory work with the machinery, and getting things ready, has commenced at the Deadwood Homestake, where it is planned to sink 1000 ft. in a search for the northeasterly extension of the Homestake orebodies. The shaft will be started 1500 ft. from the portal of a long adit, at a point about 500 ft. below the surface.

There are three candidates for the position of state mine inspector. They are R. L. Daugherty, the present incumbent, who has satisfactorily filled a 2-year term; G. D. McClellan, of Lead, and S. R. Thompson, of Sturgis. The appointment is made by the governor of the state, F. M. Byrne, who will take office on January 1, and it is expected that his selection will be announced soon after that date.

Deadwood, December 13.

## UTAH

### JUAB COUNTY

Dividends of 3, 5, and 3c., respectively, have been paid by the Colorado, Grand Central, and Gold Chain companies, the total being \$85,000, making a total of \$265,000 paid by the Colorado; \$1,654,500 by the Grand Central, and \$70,000 by the Gold Chain. High-grade ore has been opened on the 300-ft. level of the Colorado.

### PIUTE COUNTY

At the Greenhorn company's property, in the Ohio district, west of Marysville, the adit is in nearly 800 ft., and a contract has been let for driving another 100 ft. The management expects within 200 ft. to be directly under some good outcrops on the surface. The adit is to be equipped with a 6-in. pipe for ventilation, and more tools are being ordered. The face of the adit is in andesite.

### SALT LAKE COUNTY

The ore-bin at the bottom of the shaft of the Bingham Newhaven mine is nearly finished, which will allow direct transportation of its ores through the Utah Con. main tunnel direct to the tramway, and over the mountain to the International smelter. This may mean a saving of 20c. per ton.

### SUMMIT COUNTY

A movement is on foot to consolidate the various properties on the east side of the Park City district, including the McKinley, South Dakota, East Ontario, and other properties. If sufficient capital can be secured, this section could be systematically developed.

The roasting furnaces at the Ontario mill are now working, and should help to give better results. On the 1500-ft. level of the Old Ontario mine a vein carrying good ore has been opened, and a shipment will be made. The Silver King Coalition Co. has declared a dividend of 25c. per share, totaling \$312,500. G. B. Blood, superintendent of the mine, has resigned, and J. Humes, of Los Angeles, has been appointed to the position. The Daly-Judge has paid a dividend of 16c. and bonus of 15c. per share, totaling \$90,000. The company has a surplus of about \$500,000. A shipment of high-grade lead ore has been marketed from the Thompson-Quincy, and according to the annual report, the mine is opening satisfactorily. The Silver King Consolidated has shipped 40 tons of ore averaging \$4 in gold; 81.3 oz. of silver, 47% lead, and 1.7% of copper from the 1600-ft. depth. In November the Park City district shipped 6473 tons of ore.

### UTAH COUNTY

The annual meeting of the Iron Blossom Co. was held

at Provo on December 7. During the year ore production totaled 58,733 tons, the present output being 156 tons daily of high-grade ore. Lower grade will be treated in the new mill being erected. The company has \$333,807 cash on hand.

## WASHINGTON

### CLARKE COUNTY

At a depth of 1000 ft. in the Washington mine, a lode 60 in. wide carrying copper, gold, and silver worth \$100 per ton, has been cut. St. Louis, Missouri, men are interested in this property, on which \$800,000 has been spent in 10 years. There is a 100-ton mill, compressor plant, and other equipment, all driven by water-power, on the property. Two veins have been opened for long distances, and smelter returns vary from \$67 to \$165 per ton. It is intended to construct eight miles of railroad from the mine to the Washington Northern line, a logging road connecting with the Spokane, Portland & Seattle, at Prindle.

## CANADA

### COBALT

During the week ended December 6, ore shipments totaled 616 tons, of which the Coniages sent out 173 tons; Buffalo, 124 tons; Cobalt Lake, 100 tons; and La Rose, 60 tons. For the year to date the tonnage has been 20,682. Four mines sent out 150,957 oz. of bullion, worth \$95,447 during the week. The regular quarterly dividend of the Nipissing company will be paid on January 20, making a total to date of \$9,540,000.

The Alexo nickel mine at Kelso is doing well, and in November sent out 300 tons of ore, making 1321 tons since May of this year.

### PORCUPINE

A 10-stamp mill will be erected on the Three Nations mine. It will consist of a 9 by 15-in. Blake crusher, ten 1250-lb. stamps, Frenier pumps, Dorr classifiers, 5 by 18-ft. tube-mill, Dorr thickener, and six Deister-Reid slime tables. Concentrate will be stored for later treatment. The mill is expected to treat 100 tons per day.

## MEXICO

### CHIHUAHUA

The Mines Company of America has resumed paying dividends by the declaration of a distribution of 1¼% payable on January 25 to holders of record on January 10, 1913.

### MEXICO

During November the mill of El Oro M. & R. Co., treated 20,879 tons of ore, and 15,160 tons of tailing yielding \$17,980. Mining, treatment, and development cost \$118,750, while railway profit brought the total profit to \$61,870.

### SONORA

T. E. Hardly, manager of the La Barranca mine, states that 100 men are employed, and the mill and cyanide plant are working full time. Ore and concentrate is being shipped to Douglas, Arizona. A band of Yaqui Indians recently sacked La Barranca, this being the second time in two months.

At Cananea everything is working full time. The new shaft of the Capote mine is down 500 ft. Connections have been made with the old shaft at No. 3, 4, 5, and 6 levels. The new conveyor belt between the bins at the mine and at the railroad has been completed. Four Great Falls converters have been installed in the converter building. On the 800-ft. level of the Elisha mine, the new orebody has been opened 55 ft., averaging 6% copper. La Cruz mine, situated 40 miles east of Tonichi, is being developed. The Lampazos mine, owned by the Banco de Sonora, and situated in the southern part of the Moctezuma district, is again working. A concentrating plant has been built, and will treat a good deal of dump ore carrying over 40 oz. of silver per ton. The new smelter of the Minneapolis Copper Co., near Cumpas, is well under construction. Through the 'port' of Agua Prieta, mineral worth \$2,378,100 was exported to the United States, and the total for 1912 will be about \$20,000,000.

## Personal

Professional men are invited to send news of their engagements and travels. Such news is interesting to friends.

JOHN B. FARISH is at the St. Francis.  
A. W. BROWN, of Bakersfield, is here.  
JOHN A. FINCH is here from Spokane.  
A. H. PROUTY is visiting San Francisco.  
F. B. WEEKS was here on Saturday last.  
FREDERICK M. LYON is in San Francisco.  
M. A. RANDALL is here from Angels Camp.  
C. C. LANE, of Los Angeles, is at the Palace.  
G. W. METCALFE was in town during the week.  
H. W. MACFARREN was in this city early in the week.  
J. L. RAYMOND, of Fallon, Nevada, was in town recently.  
E. E. KNAPP has been called to Tuolumne county on professional business.

JAMES R. HAYDEN has returned from Seward to San Francisco for the winter.

M. S. GRIFFITHS is underground foreman at the Ojuela mine, Durango, Mexico.

G. R. DE BEQUE passed through San Francisco recently on his way to Mexico City.

S. E. VERMILYEA has been elected president of the Los Angeles Chamber of Mines and Oil.

D. C. JACKLING expects to visit the Alaska Gold Mines property at Juneau, Alaska, this month.

NORMAN C. STINES has gone to London, expecting to sail from New York on the *Cedric* early in the week.

WEBB SMITH was reappointed superintendent for the Kennedy Mining Co. at the annual meeting held during the week.

R. B. STANFORD has been appointed manager for the Bonanza mine, Cape Gracias, Nicaragua, Central America, and will leave about January 1.

HERVEY GULICK, recently of Cuzco, Peru, will reach Tacoma, Washington, about January 1, where he will have offices with W. V. GULICK, 707 National Realty building.

## Obituary

ALFRED WARTENWEILER, who died December 13 and was buried Sunday last, was one of the pioneer mining engineers of the West. Born at Kradolf, Switzerland, in 1848, he was educated at the Ecole des Mines in Paris and came to California in 1869. He was at first employed by the Giant Powder Co., but in the early seventies moved to Utah, where he took a prominent part in the development of mining and smelting in the Great Basin. One of the first trained metallurgists in the region, he contributed greatly to improvement of the crude smelting methods then in vogue. In 1879 he moved to Butte, where he became manager at the Lexington mine, and at that and other properties in the district passed the next ten years. He is best known through the West by reason of his connection with the Exploration Company and his activity in placing large American mines with English and other foreign investors. In this work he was associated with Henry Bratnaber, and the two did a great deal to build up confidence in American mines abroad. Working in connection with M. Ranvey, S. de la Bouglise, and Professor Cumenge, he sold the Boleo mines in France, and his name is associated with many other profitable ventures. An excellent judge of mines, he was conscientious and honest in his opinions and made few mistakes. He was of a genial, kindly disposition, and is widely remembered for his charitable acts. He joined the American Institute of Mining Engineers in 1875, but never found time to contribute to the *Transactions*. Mr. Wartenweiler's health broke down some months since, and his active career ended over a year ago. His death leaves a gap in the fast-disappearing circle of educated engineers who came into the West when the mining industry was young, and who, despite the supposed handicap of a scientific training, adapted themselves to conditions as they were and 'made good.'

## Company Reports

### NOURSE MINES, LTD.

The following table covers results of this company during the year ended July 31, 1912:

Ore treated, tons .....	609,250
Yield per ton .....	\$7.32
Cost per ton .....	5.40
Profit per ton .....	1.92
Profit from treatment of current ore.....	\$1,220,000
Profit from treatment of accumulations.....	42,000
Total working profit .....	1,262,000
Dividends paid .....	610,000
Cost of development, paid out of monthly profits.	330,000
Union Government taxes.....	105,000

Ore reserves now total 1,969,000 tons averaging \$6.60 per ton, of which 628,700 tons were in the Main Reef, 514,450 tons in the Main Reef Leader, and 825,850 tons in the South Reef. These tonnages are based on stoping width of 65 in., 46 in., and 49 in., respectively. Of the surface equipment, practically all the machinery for electrification of the plant is now erected and complete.

### LOST PACKER MINING CO.

This company operates a copper mine and smelter in the Loon Creek district, Custer county, Idaho, 120 miles west of Mackay, the nearest railroad point. The company is capitalized for \$750,000, in shares of \$5 each. It has a 100-ton blast-furnace, but this was not in operation during the past year, and operations in general were somewhat unsatisfactory, largely due to the scarcity of labor. The report for the year ended September 1, 1912, gives the ore in blocked form in detail, the total reserves measuring 4830 tons of first-class ore, valued at \$285,731, and 20,000 tons of second-class, valued at \$200,000. There also is much good ore filling the stopes, but this is not easy of calculation. The company began the fiscal year with a balance of \$33,086.62, there was checked out during the year for supplies, general expenses, taxes, freight, road-making, etc., \$26,913.97, leaving a balance at the close of the year of \$6172.65. There are supplies of all kinds on hand, valued at \$2392.08.

### VOGELSTRUIS ESTATES & GOLD MINES, LTD.

This company was formed in 1893 to acquire 3200 acres of property 7 miles west of Johannesburg. The authorized capital is £250,000 in shares of £1 each, and £94,100 in 6% first-mortgage debentures is outstanding. An 80-stamp mill was built in 1896. During the year ended June 30, 1912, this was employed for 363 days, the average number of stamps dropped during that period being 71.25, as against 59.2 for the preceding year. The total number of tons milled is 125,128, as against 101,033 tons last year. The working costs per ton milled (not including the accumulated slime) averaged 20s. 9¼d., showing a decrease of 1s. 10¼d. per ton on last year's figures. The gold recovered from the mill and cyanide and the by-products realized a total amount of £148,496, an increase as compared with last year of £15,827. The management has adopted a new stoping width, and after careful recalculation estimates the ore reserve at 120,120 tons, as against 147,815 tons on June 30, 1911, thus showing a decrease of 27,695 tons. The ore reserve is calculated on the South Reef alone, and does not include any of the Main Reef tonnage. The total debentures outstanding represent a sum of £94,100, an agreement having been made with the debenture-holders under which the £4110 drawn for redemption last year was treated as not having been drawn. The profit and loss account shows, after bringing forward from the mining account a profit of £8593, and after allowing for debenture interest £5646, the directors' fees £1000, depreciation on machinery and plant £8317, and sundry other items, an adverse balance of £7237, which has been carried to the balance-sheet, making, with the debit balance brought forward from last

year, a total deficit of £24,344. The policy decided upon last year has been carried out, and the operations at the mine have been conducted mainly with the view of earning as much monthly profit as possible to enable the company to meet its debts and commitments.

### SANTA GERTRUDIS CO., LTD.

The Santa Gertrudis company was formed in January 1909. The report for the year ended June 30, 1912, shows that the new mill, with a capacity of 660 tons per day, started work on June 14, 1911. During the year the two mills treated 269,839 tons of ore and tailing, having an average assay value of 52s. 11d. per ton. From this 26,000 oz. gold and 4,420,326 oz. silver were recovered; a total of £631,432, or 46s. 10d. per ton. The working cost was £355,934. After allowing for depreciation, the net profit was £252,421, of which £21,745 was written off for preliminary expenses, and there were also London expenses and taxes to pay. The sum of £207,200 was distributed as dividend, being at the rate of 15% on £1,368,000. In June the old mill was finally closed, and it is expected that the addition to the new mill, bringing its capacity to 850 tons per day, will be in working order before the end of 1912. During the year 16,249 ft. of development was done. The reserve is estimated at 586,000 tons of positive and partly developed ore, and 551,000 of probable, calculated to yield a profit of \$7,475,000.

### MESSINA (TRANSVAAL) DEVELOPMENT CO., LTD.

The Messina (Transvaal) Development Co. was formed at the beginning of 1905 to acquire a copper property consisting of ancient mine-workings in the north of the Transvaal near the Rhodesian border, 130 miles from Pietersburg. The deposit is rich, but progress has been hampered by the absence of communication with the outside world. Much high-class ore has been mined, chiefly during development, and sent to Swansea, but at a prohibitive cost for transport. Before long the mine will be provided with railway facilities, for lines are being built both from Delagoa Bay and Pretoria to connect eventually with the Rhodesia railway system. At the present time the Pretoria railway is being extended from Bandolier Kop, the present northern terminus, to Messina, a distance of about 100 miles, and the work should be completed by the middle of next year. The railway is being built by the Government, and the company guarantees for 10 years to make good any loss on the working of the line, the amount payable in any one year not to exceed a sum equal to 4½% on the estimated expenditure, £426,831. Connection with Delagoa Bay, through the Selati railway, will no doubt come within a few years' time. The report for the year ended June 30 last shows that 6781 ft. of development was done at a cost of £21,928. Of this, about 2500 ft. was on the lodes, and the part sampled, 1533 ft., gave an average assay-value of 13.1% copper over an average width of 60 in. The content is so far fully maintained down to the lowest workings, and the width of the bonanza orebody increases steadily from the fourth to the eighth level. The copper minerals are chiefly bornite and chalcopyrite, occurring in massive form. The ore reserve is calculated at 170,000 tons, averaging 10% copper, and in addition the probable ore is estimated at 200,000 tons. During the year 9609 tons of development ore was raised, averaging 9% copper, and 10,347 tons was milled; 1162 tons of concentrate was recovered averaging 49.8% copper, together with 836 tons of middling averaging 14.2% copper, to be re-treated later. The tailing and slime are being stored. The amount of concentrate shipped was 1119 tons, and it was sold for £29,761. The cost of mining and milling was £15,868, shipping charges were £6003, Johannesburg expenses £4610, London expenses £6472, development-redemption £2586, allowance for depreciation £2697, making with other small items a deficit of £4674. Debenture interest was £5181, and expenses in connection with the issue were £809, so that the final debit balance carried to the balance sheet was £10,666.

## Concentrates

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

**B**ENDIGO, Australia, has produced 44 gold nuggets of and above the weight of 20 oz. each, found within the auriferous area comprising the goldfield. In 1852 the largest was found, weighing 573 oz., followed by others of 384, 377, 338, and 332 oz. respectively.

**H**IGH-SPEED tool steel is most durable at approximately the same speed at which ordinary carbon steel is most durable, but it greatly exceeds ordinary steel in length of life at the temperature thus produced.

**A**LLOYS containing about 36% iron, 60% chromium, and 4% molybdenum are insoluble even in aqua regia, but can be worked in the ordinary way. Fair results, but not so good, are obtained when vanadium or titanium is substituted for molybdenum.

**T**HE total production of all metals in the United States in 1911 was 27,878,282,094 tons, valued at \$788,925,046. according to the U. S. Geological Survey. The total output of all ores was 105,258,492 short tons. Pig iron from domestic and imported ores amounted to 26,048,162 short tons, valued at \$327,334,624; while the output of platinum was 0.999 ton, valued at \$1,308,480; and gold 190.704 tons, valued at \$114,981,080.

**M**UCH American phosphate rock is shipped to Europe to be manufactured into superphosphate, which is valuable as a fertilizer. Exports of raw phosphate rock to Belgium in 1910 were valued at \$400,000, and imports from that country for the same year were valued at an equal amount. The opinion of the United States Consul at Chemnitz, Germany, is that the superphosphate could be made more cheaply at home.

**L**IME is generally used in cyanide treatment in preference to caustic soda, which often causes undesirable results in the zinc-boxes. There are times when freight plays a part in the choice of alkali, and at the Associated Northern mill, at Ora Banda, Western Australia, it was found that one ton of caustic soda would do the work of 30 tons of lime, of which the freight over 20 miles of road was the main item of cost.

**E**QUIVALENTS for the terms 'arroba' and 'carga' used in Mexico, are as follows. The arroba is 11.5 kg. or 25.3 lb.; the carga, of all kinds of merchandise and material, is 12 arrobas, 138 kg., or 303.6 lb.; the carga of lime is 14 arrobas, or 354.2 lb.; the carga of charcoal is 8 arrobas, or 202.4 lb.; the carga of 'panoche' (brown, unrefined sugar) is 10 arrobas, or 253 lb. The literal translation of 'carga' is 'load'; that is, a mule-load.

**L**INOLEUM tops for Wilfley and Deister tables have been found at Tonopah to rot away in a few months from the probable action of hot cyanide solutions. To prevent this, at the West End mill, stout canvas is put on in place and given two coats of P. & B. paint, and acts well, lasting upward of 12 months. This black paint would prevent the work of the table being watched at the concentrate discharge end, so the last 12 in. is given two coats of non-acid white paint, which shows up the concentrate plainly.

**R**EGRINDING 12-mesh pulp from stamps by Chilean and Huntington mills, results have shown that upkeep of the latter is much higher per ton of ore reground than the former. Steel consumption is also about twice as much in the Huntington. At one plant in Nevada these mills have 35 to 40-mesh screens, and the Chileans 24-

mesh. With this screen the latter will give a finer discharge, and handle a larger tonnage per mill, than the former. The power consumed is 12 hp. for Huntington and 35 hp. for Chilean.

**V**ALUES of metals undergoing treatment at smelters are segregated under the heading 'metals in process,' and it has been suggested that Rand or other mining companies use the phrase 'gold (or silver) in process,' to similarly include the metals in the partly treated ore, the circulating cyanide solutions, the undissolved zinc, slag, and other by-products. This would necessitate on clean-up days a general knowledge of the weight and metal content of materials in the various stages of treatment, and together with the weight and value of ore and tailing during the month, would enable the metallurgical balance-sheet to be constructed with a fair degree of accuracy.

**N**EW YORK CITY adds another big city's population, about 125,000, to itself every year, and water-supply is of the greatest importance, so a scheme is well under way to obtain 500,000,000 gal. per day from the foothills of the Catskill mountains. The cost is estimated at \$176,857,000, of which about \$100,000,000 had been spent to March 1912. There are four distinct types of aqueduct, namely, cut-and-cover, of 55 miles length, constructed of concrete in horseshoe shape, 17 ft. high by 17.5 ft. wide; 24 grade tunnels, of 14 miles length, of horseshoe shape, 17 ft. high by 13.3 ft. wide, lined with concrete; 7 pressure tunnels, of 17 miles length, of 14-ft. drain, lined with concrete; and 14 steel-pipe siphons of 6 miles length, 9 to 11-ft. drain, lined with 2 in. of cement mortar.

**S**EPTIC tanks operate in the absence of light and air, the bacteria producing in the decomposition of organic matter of sewage, quantities of reducing gases. Among these decomposition products is observed more or less hydrogen sulphide gas, resulting in most cases from the decomposition of organic sulphur compounds existing in the sewage. In most tanks of this character, the amount of hydrogen sulphide thus liberated is not sufficiently large to cause complaint. Attention has been directed at Los Angeles to the disintegration of cement mortar in concrete resulting from sewer gases, and this is proved to be from the formation of sulphuric acid upon walls and roof of tanks, which attacked the cement, giving calcium sulphate, or gypsum, as a final product. It has been observed that the amount of acid formed appeared to be too large to have been produced by the organic sulphur compounds in the sewage proper; and it is suggested that the only possible sources of this excessive amount of sulphur were the oil wells and the sulphur which is always present in small quantities in normal sewage.

**W**ATER flowing through a pipe containing a contraction shows a pressure at the throat less than at the inlet, due to the increased velocity in the throat. In a properly proportioned pipe this pressure is almost entirely regained at the outlet, this, in turn, being due to the decrease in velocity after the water passes the throat. The temporary loss in pressure at the throat can be accurately measured by a U-tube containing mercury, and it is found to increase approximately as the square of the throat velocity; that is to say, if the velocity of the water at the throat doubles up, the difference of mercury-level becomes about four times as great. This is the principle of the Venturi meter, used on large water-pipes in steel plants in the United States, and exclusively on the conduit of the Coolgardie Water Scheme, in Western Australia. In the latter plant, the mains are 30 in. diam., but at the meter are reduced to about 10 in. diam., the piezometer tubes being about 1/8-in. bore. In various towns and mines forming this system, the Kennedy water-meter is used almost universally. In this type all the supply to individual consumers passes through. This type of meter is also suitable for measuring hot water, as there is an absence of mechanism or projections within the tube.

## EDITORIAL

NOW the Candy Trust is to be dismembered. A sweet job, undoubtedly. Oh, fudge.

MEXICAN customs duties have lately been increased and there have been persistent rumors that taxes on mines were to be raised. No move has yet been made in that direction by the National Congress, and doubtless such increase will be at least deferred as long as possible. The Mexican Government derives a considerable revenue from the mining industry and would hesitate long before taking any step that would check development.

DISTRIBUTION of an extra dividend of 15 per cent is the form of Christmas present proposed for the shareholders of the Homestake Mining Company. Production of gold during the year has increased, and expenditures on betterments have been so liberal during recent years that there is no longer need to divert considerable sums for this purpose. Good business and technical management has here yielded good profits from a good mine.

ESTIMATES of the gold production of Porcupine for the year are given as \$1,800,000, nearly equally divided between the Dome and Hollinger mines, though the Vipond and McIntyre contributed small amounts. With new mills in operation the output during 1913 should show a good increase. Porcupine has not attained the heights of lurid promotion literature, but it has done something better, developed into a quiet and steady producer.

TARIFF discussion divides families, and we have many friends on both sides of the question. We cannot forbear, however, to express the opinion that the tariff on zinc-dust is unnecessary and results only in increasing by some 20 per cent the cost of this article to gold miners. As zinc-dust is a by-product from zinc smelting that was long a nuisance and which can be marketed at little cost, we see no reason for protecting this particular infant industry. The practical result is to put one more difficulty in the way of treating low-grade gold ores.

NEVADA, like some of her citizens, is seriously considering the high cost of living. A non-partisan movement has been started to devise means of decreasing the expense of the state government. The system of dual government that obtains in the United States is admittedly expensive. The burden falls especially severely upon the people in those states that have large area and relatively little population. Elbow room costs, even under pioneer conditions. The spirit, however, that converts a desert into gardens can be trusted "to find a way."

JOPLIN operators are taking keen interest in the appointment of mine inspectors about to be made. In the old days, mine inspectors were too frequently considered necessary evils to be tolerated only and to be disregarded as much as might be. This was less because operators desired unsafe conditions than because the inspectors chosen

were, in most states, incompetent political favorites. As the character of the men appointed has risen they have gained the respect of both men and operators. There have always been some good inspectors; we hope the time is near when there will be no poor ones. The position is one of large usefulness and responsibility, and appointments may well receive the careful scrutiny of all concerned with serious mining.

**M**INE OWNERS have been coöperating with the tax commission of Arizona in the effort to devise a system for fair taxation of mining property. According to press reports, the plan that will be proposed to the legislature next month will involve a levy on the total net proceeds, to which will be added a tax of 12½ per cent on the gross value of bullion produced. Physical improvements are to be taxed on the basis of actual value. The arrangement cannot be criticized until details are at hand, but we commend unreservedly the spirit indicated by the friendly co-operation of the commission and mine owners. No one likes to pay taxes, but all should. The essential thing is to agree on a fair basis of taxation.

**G**OLD and silver by the ton is, to most of us, mentally associated with the graphic tales of H. Rider Haggard and other romancers, yet it is a not at all uncommon sight in modern life. A single shipment of silver bullion recently made by the Rio Plata Mining Company in the Arteaga district of Sonora, amounted to nearly five tons of metal. It was not 'a king's ransom,' in time-worn phrase, being valued at only \$180,000. The gold received at the San Francisco mint during November amounted to over seven tons of metal, valued at \$4,300,000. The stock of gold coin and bullion in the United States Treasury on June 30, 1910, was nearly 1750 tons, valued at \$1,044,000,000, while national and private banks and individuals possessed nearly a thousand tons more, valued at \$600,000,000.

**V**IGOROUS protest is being made by prospectors in the Centennial district, Albany county, Wyoming, at a return of \$43 from a shipment of nine tons of ore that was believed to be extremely rich and on which \$90 freight had been prepaid. Of the details of this particular case we have no knowledge, but it may serve as an example of the frequent discrepancy between assays of hand specimens and the sampling of carload lots. Much of the resentment visited upon the 'smelter trust' doubtless has a similar origin. The smelters are, like any other merchants, anxious to buy as cheaply and sell at as high a price as possible. Rates which often seem unjust to the shipper are based upon the fundamental laws of supply and demand, and ore which at New York prices has considerable value, may be worth but little at a smelter where an ample supply of similar material is available. In many cases complaint has been justified, but on the whole smelters deal fairly with their shippers, since in this as in any other business a reputation for fair dealing is a valuable asset.

**V**ISITORS to the packing-houses of Chicago or Omaha are always entertained by the ancient jest that no part of a pig is wasted except his dying squeal. In a similar vein a daily journal notes that kidney pills are one of the by-products of the Pioneer Iron Company, at Marquette, Michigan. The company is engaged in the manufacture of charcoal iron, and recovers the by-products incident to the conversion of wood into charcoal for its furnaces. As is well known, the number of possible products from the destructive distillation of wood is very great, and includes many of the most useful substances employed in the textile industries and in medicine. Utilization of materials for-

merly wasted is now the order of the day, and such a modern plant as that of the United States Steel Corporation at Gary, Indiana, is at once an inspiration and an object lesson. We have progressed far from the days when the cave man required only some fruit, nuts, and meat, with skins for his covering. The present-day workman demands and expects comforts and luxuries unknown to medieval kings. So great an increase in general welfare demands the conservation of what we possess and care and attention to its increase. Life is now intensive as well as strenuous.

**M**ISUSE of the terms 'build,' 'construct,' 'erect,' and 'install' is a common fault of engineers, for, strangely enough, men who would ridicule an attempt to couple pipes with a monkey-wrench do not exhibit an equal amount of discrimination in regard to choice of words as they do to choice of tools. In such a case words may belie actions, for the natural inference of the thoughtful reader or listener is that a man who is careless in his speech or writing is probably equally slovenly in his work. Install is so often misused in connection with construction work that some careful writers abstain from using it. This is unfortunate, for in its rightful meaning of 'to put into position for work,' it is an extremely useful word that cannot well be spared. For example, a mining company builds a shaft-house, and a manufacturer constructs a hoist, which is then installed in the shaft-house. In his shop the manufacturer makes the parts of the hoist, and when they are finished, he erects or assembles the hoist before it is shipped to the mine. All the verbs in these two sentences are correctly used. Construct, from a Latin root, is almost synonymous with the Anglo-Saxon word build, but not exactly so; thus it might be said that an additional window was constructed (not built) in the side of the house. Erect has the idea of elevation; a tower is erected, constructed, or built; a ditch is dug or made. A thing is made from raw materials, or erected by joining together component parts; thus the parts of a stamp-mill are first made of wood and iron, then erected. Both construct and build have a sense of importance; the contractor builds a residence or constructs a bridge, and in his leisure hours makes a doll house for his little daughter. To install is simply to put in place; a hoist may be installed, but not a tramway or an ore-bin. To convey to the mind of another person the precise mental image of the speaker or writer is at best a difficult task, without careful attention to the forms of speech employed it becomes impossible.

**C**ASTE is the outcome of one of the most futile of traits of human character. We are prompted to this reflection by the undercurrent of thought which runs through several of the letters we have received concerning 'Sticking to the Job,' indicating that many consider that an engineer who has discontinued the practice of his profession to engage in other forms of useful and profitable endeavor thereby loses caste. In a similar vein a civil engineer recently remarked, in response to a suggestion that he join an engineers' club, that a great many of the present members were mining men; the inference being that civil engineers are professionally superior to their colleagues of the mining profession. Invidious comparisons of American, British, German, French, and other technical men are all too frequent. Such concepts are fundamentally unscientific. The man who does good work in a becoming manner earns respect, and the degree of respect should be measured by the amount of brains required for the performance of the work. Graduation from a school of mines does not impose on a man any obligation to engage in the technical work of mine operation. Provided due attention has been paid to the study of mechanical problems, the young man

who has received a thorough education in mining engineering is better equipped than a civil or mechanical engineer to engage in general business work, nor is there any valid reason why he should not do so. The danger from increase in the number of mining schools lies not in the increased number of graduates, but in the tendency of small schools to 'let through' as many students as possible in order to swell the roster. If many young men, after a few years experience, leave mining work for other fields, the chances are that those who remain will be more earnest and efficient. Success in useful endeavor is the proper goal, and the man who preserves his self-respect need not fear the sneers of those who affect superiority.

### A Geological Survey of California

A little over fifty years ago California undertook a serious scientific study of her mineral resources. After a short preliminary period during which J. B. Trask directed the work, J. D. Whitney was called from the East. He gathered round him a brilliant staff—Clarence King, W. H. Brewer, J. T. Gardner, W. M. Gabb, William Ashburner, C. F. Hoffman, and the young volunteer R dmond, "with as good a natural gift for finding fossils as anyone I ever saw," as Whitney says. Probably no more competent, and certainly no more hard-working and enthusiastic corps could have been assembled. With various ups and downs, the work continued until 1874, when the Legislature refused to appropriate further funds. It was not the first time that the money had failed. At one time the state was in arrears \$25,000 to Whitney and his brother, who financed the work when official funds ran short. Those were days of unsettled ideals and much bitter controversy. Gilman had a stiff fight to keep the University from being converted into a manual training school, and it is not surprising that, with "\$40,000,000 in worthless stocks to be floated," the so-called 'practical mining men found themselves in sharp disagreement with Whitney. It would be unprofitable to go into old quarrels. Perhaps the fault was not all on one side. The serious result was that the state lost the services in the development of the mineral industry of a most competent corps of scientists. When after a few years this lack came to be felt, the State Mining Bureau was created and started under the capable leadership of Henry G. Hanks. Other men succeeded him, but the work changed in character, and in time the Bureau became a moribund institution afflicted with dry rot and devoted to the uses of petty politics. Something over a year ago Mr. Hiram Johnson, as Governor, and acting on the advice of leaders in the mining profession, appointed Mr. W. H. Storms to the position of State Mineralogist, and better conditions began to prevail. Without funds, however, even the best of officials can do little, and the routine work of the Bureau has come to absorb the whole of the present income.

Elsewhere we present a statement from Mr. Storms of the present condition and needs of the Mining Bureau. We commend it to the careful study of our local readers. We note with interest and pleasure that Mr. Storms asks for funds to resume the work of making a geological survey of the state. This, if it be done, will meet a very real need. For years fundamental studies of the state's resources have been neglected. The bulletins issued by the Mining Bureau, excellent and timely as many have been, are mainly rehashes of old information. This is proper enough if only the functions of a bureau of information are taken into account, but old information loses value. There should be some provision for keeping abreast of the times in other ways than merely collecting statistics of production. A wholly new California is being created.

Knowledge of ore deposits and of mining methods that was ample a quarter of a century ago is but poor material for directing exploration and investment today. The library, reading-room, and museum, the services of a determinative mineralogist, the answering of inquiries, all these are useful, and in supplying these wants the State Mining Bureau performs an excellent public service. This needs to be complemented by some organization devoted to fundamental studies of the composition and structure of the earth's crust if California is to wisely and rapidly develop her mineral resources. The existing Mining Bureau provides for much that in other states falls on a geological survey. The state is already carrying the heavy overhead expense, but falls short of reaping full benefit. If California is to be in the front rank of the newer move for the "maximum of use with the minimum of waste," the state should have the exact and unprejudiced information that it is the function of a geological survey to collect. To do things half way is poor economy, and whether in the particular manner that Mr. Storms has suggested or in some other, provision should be made by the Legislature about to assemble for filling in this gap in the work of the state.

### Panama Canal Tolls

Panama canal tolls are to the fore again, owing to the British protest recently made public. Briefly, it is complained that relieving our coastwise shipping from payment will automatically increase the rates on foreign shipping if expenses are to be met and a sinking fund provided; that discrimination invites more discrimination and may open the way to free tolls for all American ships; and that the provision against use of the canal by railway owned ships interferes improperly with the activities of Canadian roads. We are not deeply impressed with these arguments, but neither are we concerned for free tolls. Panama canal tolls have been fixed by competition, and so long as the Suez canal route remains in foreign hands no rates can be maintained that are not competitive. Whether few or many ships be exempted from payment is not likely to change the rates. No foreign vessel can enter the coastwise trade of the United States, and its regulation is a purely domestic matter. For our part, we think this very fact affords the American owners of coastwise vessels sufficient protection, and that free tolls are unnecessary. The provision against railroad owned ships was placed in the law to prevent repetition of the conditions under which the Pacific Mail Steamship Company for years ran ships to discourage through traffic by Panama. Old sores heal slowly, and while the jurisdiction of the Interstate Commerce Commission is now broad enough to meet the situation, there can be no doubt that the people are suspicious and also firmly determined that the railroads shall not dominate the canal. The problem of transcontinental freight rates is a domestic one of vital importance to many people. It may be foolish to prevent railway owned ships from using the canal, we believe it is, but it is certainly a matter that concerns us only. There is, we believe, no interference with such ships in foreign trade, and if the Canadians wish to have railway owned ships 'competing' with their railways, doubtless they may be accommodated. None of the provisions to which objection is made appear to us to be vital, though why Great Britain should question them is not evident. What is important, is that we have apparently blundered into a position that we seem afraid to defend before an international court of arbitration. This is serious. If Congress is not sufficiently sure of its position to warrant going into court, by all means repeal the law. The matter itself is not important, but the good faith and good name of the country must be preserved.

# Mining on the Panama Canal

By C. R. FORBES

The Panama canal is attracting especial attention just now on account of its nearing completion, and while all are familiar with the magnitude of the work, the difficulties encountered, the great sanitary victory, but little has been written describing actual details of value to the engineer. The following notes concerning the method of working in the big cut at Culebra were taken during a brief visit to the canal, and will perhaps be of especial interest to the mining engineers, since the work is similar to that of many of our large mining operations.

## METHOD OF ATTACK

The method of attacking the cut is similar to other steam-shovel work and consists in first taking a 'pioneer cut' through the centre of the canal. This cut is about 12 ft. deep and from 40 to 45 ft. wide; the shovel operates in the bottom of the cut and works against the 12-ft.

be no chance of delay from the drilling and blasting operations. For breaking the pioneer cut, the holes are placed as below.

The distance between holes will depend upon the kind of rock to be broken, and varies from six to ten feet. Most of the rocks are comparatively soft sediments, some of which could almost be excavated without blasting, but in places the sediments have been intruded by dikes of basalt or trap that are very hard to drill and require much powder to break.

The holes for breaking the pioneer cut are drilled 15 ft. in depth to the so-called 'powder grade,' which is three feet below the grade at which the shovel works; this is done to insure that the powder will be placed below the shovel grade and thereby diminish the danger of encountering any unexploded powder with the dipper. In breaking the ground for the second and succeeding cuts, holes

MAKING PIONEER CUT.

PLAN OF PIONEER CUT.

face, loading into cars on the loading track as shown in the photograph and sketch. The shovel track is composed of 6-ft. sections which can be moved from behind the shovel, carried ahead, and bolted to the preceding section. The work of moving ahead is done usually while waiting for cars, but if this is not possible, little time is lost, because it can be accomplished in a very few minutes.

Following the pioneer shovel, another one, at some distance, takes the second cut as shown; the second shovel works against a 24-ft. face and loads into cars on a track placed in the original pioneer cut. In both the pioneer cut and the second, the loading tracks are 12 ft. above the shovel tracks; this distance is determined by the height to which the dipper can be raised, and must be such that it can easily clear the loaded cars when drawn up to its maximum height. After this cut has been taken, it may be widened to any width by other shovels working against the 24-ft. face on one side or the 12-ft. face on the other, and loading to a central track as shown in the sketch.

The work is continued in this manner until the desired width is obtained, when a new pioneer cut is started and the work of deepening the canal is repeated as before. The work may be carried on at many different places and with many variations in the above plan which may be made necessary to provide suitable grades for tracks, proper drainage, etc., but this is in general the plan followed.

## BREAKING GROUND

The ground is broken a considerable distance ahead of the shovels, as a rule, in order that there may be no danger of injury from the blasts, and also that there may

are drilled to a depth of 27 ft., thus making the bottom of the holes or powder grade 3 ft. below the shovel as before. The arrangement of these holes is practically the same as that used in the pioneer cut, the distance apart depending also upon the nature of the rock.

Another method of breaking the ground after the second cut has been taken, is by drilling flat toe holes into the bank, as shown in the diagram; these holes are drilled alternately 15 and 30 ft. deep and from 3 to 5 ft. apart, and are bottomed 3 ft. below grade as before. These flat holes seem to give the best results and are used whenever possible.

## CHARGING AND FIRING

The loading of the holes is in charge of a 'powder boss' who determines the amount of powder to be used and supervises the loading. All firing is done by electricity and all possible precautions are taken to prevent misfires; the wiring and shooting are done by an electrician and his gang, who are responsible for this part of the work. Dynamites of 45 and 65% strength are used almost exclusively. All holes are sprung before being shot, and usually they are sprung several times. At one place where I observed the work in a comparatively soft shale, the pioneer-cut holes were being sprung twice, first with 1½ lb. of 60% dynamite, then with 5 lb., and a final charge of 20 lb. used in the centre rows and 15 lb. in the outside rows. It is quite probable that this charge would have been sufficient for a considerably harder rock.

The deeper holes are sprung four or five times, and some of the 30-ft. toe holes in hard rock are sprung six

times and finally charged with 150 lb. of dynamite. A push-down battery is used for firing the springing shots, but for firing the final charges a 110-volt lighting circuit is used with the holes connected in parallel. The wires carrying this current run along the banks of the canal and at frequent intervals are connected with firing-

LOADING A ROUND OF SPRINGING SHOTS.

boxes containing a switch. These boxes are kept locked, and, as a further precaution against an unauthorized person attempting to fire a round of shots, it is necessary to make two different connections before shooting, so there is little danger from this source. Every precaution is taken to prevent missed holes; the maximum number of holes fired at one time is 150, although it is uncommon to fire more than 100 at once. Since the adoption of the

CROSS-SECTION OF SECOND CUT.

TOE HOLES.

present firing system few misfires have occurred, but before that when batteries were used they were not uncommon. The accompanying photographs show the men engaged in loading a round of springing shots and the shot itself. Note the long wooden poles used in lowering the powder into the holes.

#### DRILLING

Two types of drills are used, the well drills or churn-drills, and the ordinary compressed-air piston drills, known on the canal as tripod drills. The well drills are worked in batteries of six, as shown in the accompanying photographs, and are run by compressed air. The rate of drilling with the well drills varies from 20 to 75 ft. per day, depending on the kind of material, depth of holes, etc. Most of the drilling is done with the well drills, as they are more easily handled than the tripod drills in making

deep vertical holes. When very hard rock is encountered these drills are too slow, and then the tripod machines are used. These machines are large piston drills of the tappet valve type, with  $3\frac{1}{4}$  by  $3\frac{5}{8}$ -in. cylinders. The tappet valve has been found most suitable for drilling these deep holes, as its positive movement insures a powerful return stroke which is essential when drilling a vertical hole 27 ft. deep. The rate of drilling varies from 20 to 30 ft. per day in hard rock for holes 27 ft. in depth and bottomed 2 inches in diameter. The accompanying photograph shows a group of tripod drills at work. Note the long piece of steel in the hands of one of the drillmen.

WIDENING AFTER SECOND CUT.

I was surprised at the class of labor employed on these machines, as they are practically all Jamaica negroes and the highest paid receive but 20c. per hour. Their skill, however, in handling these big machines is remarkable, and much credit is due the foreman for the patience that must have been necessary to develop these untrained negroes into skilled drill runners. In discussing this matter with the foreman, I was informed that many of these poorly paid men were the equal of many American drill runners, and from a brief observation of their work I would judge such to be the case. When the work was first started drill-runners were sent down from the States and were paid good salaries for this work, but they required two helpers and refused to do anything but crank

MAKING SECOND CUT.

the machines, so they were gradually displaced by this cheaper class of labor.

The work of taking down the slope or bank of the canal is done by drilling holes with tripod drills at the angle of the slope; these holes are placed close together and are met within one foot by other holes drilled horizontally in the foot of the bank, so that small charges of powder are sufficient to break the rock back to the slope without loosening the remaining material. The drilling of these slope holes is extra difficult and hazardous work, as the machines are mounted in some cases on a very narrow ledge of rock and perhaps beneath an overhanging cliff from which rocks are liable to fall. One of the few recent accidents was from this source, and three men were killed by a big boulder coming down upon them while they were engaged in drilling these slope holes.

COST OF WORK

The following figures taken from the *Canal Record* of August 7, 1912, give an idea of the cost of the excavation work on the canal. These figures are the average for April, May, and June, and for a quantity of 4,386,000 yards:

	Per cu. yd.
Drilling .....	\$0.047
Blasting .....	0.054
Loading .....	0.050
Tracks .....	0.065
Transportation .....	0.077
Dumps .....	0.023
Pumps .....	0.004
Maintenance of equipment.....	0.077
Plant arbitrary .....	0.030
Division expense .....	0.017
Administration .....	0.033
<b>Total .....</b>	<b>\$0.479</b>

From the above figures it may be noted that the cost of the work is a trifle less than 50c. per yard, and of this

AIR-DRILLS.

CHURN-DRILLS.

amount the largest single item is that of transportation. The work of excavating the Culebra cut is not a question of steam-shovel capacity, for very few of the shovels are run to their maximum capacity; it is not a question of drilling or blasting; but the great problem is that of transportation, of getting the cars to the shovels and away from them in the shortest possible time. Obviously, in a narrow cut, several miles long and with room for only a few tracks, it is not possible to keep every shovel going continuously, but the percentage of time lost in waiting for cars is remarkably small, considering the difficulties, and is kept to a minimum only by having tracks in such condition that trains can be moved rapidly without constant fear of accident and maintaining plenty of good rolling stock with competent train crews.

PERU possesses great areas of alluvial gold country and quartz mines. Tentative efforts have been made to solve some of the problems, and in two cases, large plants have been started, notably the Apurima Goldfields and the New Chuquitambo Gold Mines. The new cyanide plant of the latter company must be adapted to deal with copper in the ores. News comes from Apurima that the first clean-up has taken place since the installation of the hydraulic plant. The Poto hydraulic plant is working steadily. There has been an influx of miners, overflowing from the Bolivia stampede to Tipuani. The New Chuquitambo company, near Cerro de Pasco, has started to sink an incline shaft to open up its ground below the Santiago tunnel. During September the Cerro de Pasco smelter produced over 4,000,000 lb. of copper, and as soon as improvements are completed, there will be a further increase.

## The Tomboy Mill

This mill consists of 60 stamps and a concentrating and cyanide plant. During the year ended June 30, improvements were made and the following details are published in the recently issued annual report. The grading plant, consisting of three Wilfley tables and one Deister slimer, receives the mixed concentrate of the Wilfley tables, and the entire concentrated product of the Frue vanners, and turns out a finished product of high-grade galena concentrate, over 60% Pb, carrying much gold; a zinc concentrate containing 24% Zn, and higher; and an iron product which, under the present smelter schedule, commands a much more favorable price for gold, silver, and lead than when, formerly, the iron was included in the zinc concentrate.

Previous to remodeling of the concentrating room, the treatment of the entire mill product was accomplished by means of 15 Wilfley tables and 12 Frue vanners. Of the former, four were restricted to re-treatment of middling and concentrate, leaving 11 for the actual work of primary tables. The construction of the grading plant for re-treatment of concentrate liberated two Wilfleys, while the sending of the middling to the middling plant released two more

Wilfleys for the concentration of original feed. The addition of two new Wilfleys on the north end of the mill, three on the south end, and the installation of two Wilfley roughing tables, which materially relieve the work of the other tables, makes 22 tables working on primary feed.

The middling plant was designed by Gelasio Caetani for the re-treatment of the high-grade tailing, which repeated tests proved to be contained in that portion of the tailing nearest the middling streak on the Wilfley tables. The feed to this plant will be obtained from the higher grade portion of the tailing discharged from the Wilfley roughing tables, and the high-grade tailing from the primary Wilfleys. The plant consists of two Hardinge conical tube-mills for re-grinding, eight copper plates for re-amalgamation, classifiers, seven Callow tanks, seven Deister slimers, and eight Wilfley tables for the re-concentration of the re-ground middling product. For the relief of the filter plant this year, and with a view to its entire replacement in the future, it has been decided to employ four 10 by 32-ft. Dorr thickeners. It is hoped that these improvements in the recovery of clear water will permit of the maintenance of increased tonnage due to new plant throughout the year.

During the year ended June 30, 1912, the mill treated 107,577 tons, yielding \$954,981, at the following cost:

Milling, per ton .....	\$0.67
Concentrating, per ton .....	1.00
Water supply, per ton.....	0.19
Assaying, per ton.....	0.04
General and taxes, per ton.....	0.59

**Total, per ton .....** **\$2.49**

# The California State Mining Bureau

By WILLIAM H. STORMS

\*Before the fortuitous discovery of gold by James W. Marshall, at Coloma on the American river in 1848, California was little known to the world. It was believed to be inhabited by a few thousand Indians, commonly referred to as 'Diggers.' The civilized population was largely of Spanish-American birth, and the life and customs of the Spanish people were strongly impressed upon everything, educational, commercial, and religious, in California. Gold had been discovered and mines worked at various places in the southern portion of the state, notably in Los Angeles and San Diego counties, but as these deposits, although profitable, were limited in extent, they created no more than a local interest. The discovery made by Marshall, however, came at a most opportune moment in our history. The news of the discovery of gold spread rapidly and reached to every part of the civilized world as fast as the means of communication of those days permitted. Thousands of men set their faces toward this El Dorado, and within two years California had accumulated what at that time was probably the most cosmopolitan population in the world. The wonderful development of the Golden State from that date is familiar to all. Since the discovery of gold at Sutter's mill, California has produced more than \$1,500,000,000 worth of gold, the greatest yearly production being made in 1852, when it exceeded \$81,000,000. This was largely due to the unprecedented yield of placers.

Today, although the production of gold has decreased, the annual output is still large, approximating \$20,000,000. The development of the other mineral resources of the state has, however, continued uninterruptedly, until the total output now exceeds \$80,000,000. Although these resources have been exploited with energy for more than sixty years, the possibilities of new development and of still greater yield in the years to come, are evident to all who are familiar with our mineral industry. So rapidly were the mineral resources of the state developed, in those early days, particularly the gold deposits, that the greater importance of the mining industry was early recognized, and the necessity for scientific and systematic knowledge soon became apparent.

Prior to this there had been more or less desultory geological work done in California, the first exploring expedition of this character being made in 1838 to 1842 inclusive. James D. Dana, who in after years came to be recognized as one of the foremost authorities on mineralogy, was geologist of this expedition, and James Hill was geologist for another expedition which did considerable exploratory work in California under John C. Fremont in 1843-4. Several others in years immediately subsequent to this made geological researches in various portions of the state, among these being Philip P. Tyson, William P. Blake, and John B. Trask. This latter gentleman was, in fact, the first officially appointed geologist of California, he acting under authority of the State Legislature in 1853. On April 21, 1860, the State Geological Survey of California was created by the legislature and J. D. Whitney was appointed state geologist. Mr. Whitney continued in this office until the State Geological Survey came to an end by the refusal of the legislature of 1873-4 to make an appropriation to longer continue the work so ably carried on by Mr. Whitney.

For six years or more, nothing of an official nature was done to aid the study of the geology of the state or to promote its mineral industry. In 1880, however, the great and growing importance of the mineral resources of California was once more officially recognized, and the earnest efforts of the friends of the industry were rewarded by the creation of a state department of mines, to be known as the State Mining Bureau. This was done under the direction of the twenty-third legislature, which also created the office of State Mineralogist. The bill which created the State

Mining Bureau required that the principal office of the Bureau be situated in the city of San Francisco; that the State Mineralogist should collect mineralogical and geological specimens throughout the state and place them in a permanent exhibit; to provide and maintain a library of works on mining, mineralogy, and metallurgy; and also to annually make an official report to the governor, giving data and information as to the conduct of his office and of the State Mining Bureau.

Henry G. Hanks was appointed mineralogist by George C. Perkins, then governor. The early reports issued under the administration of Mr. Hanks were most helpful to those engaged in the mineral industry and are now difficult to obtain. The first situation of the State Mining Bureau and the mineral specimens collected by Mr. Hanks was in San Francisco on the south side of Pine street between Sansome and Montgomery. Here, in a suite of three rooms, were the office of the State Mineralogist, the library, and the museum. Mr. Hanks' first report contains the following in reference to these: "The collection embraces 1327 specimens from all parts of the Pacific Coast, many of them of special value. The library numbers 78 volumes and 25 pamphlets." After occupying the Pine street quarters for about a year, the Bureau was removed to Sutter street where the office and library were situated on one floor and a large room on the floor above was used for display of the rapidly accumulating mineral collection.

Mr. Hanks was State Mineralogist until May 30, 1886, when he resigned, and was succeeded by William Irelan, Jr., who was appointed by Governor Stoneman. Mr. Irelan had been chairman of the board of trustees of the State Mining Bureau, and at once assumed the duties of office. The sixth annual report states that 7000 specimens were collected and displayed in the museum during the administration of Mr. Hanks, and to this collection Mr. Irelan added 2000 more during his first year as chief of the department. It is worth noting that in July 1912 the museum contained not less than 17,500 mineral specimens, besides which the State Mining Bureau has distributed thousands of classified specimens of the rocks, ores, and minerals occurring in the state, to educational institutions throughout California. There is now on exhibition in the Bureau, in the Ferry building in San Francisco, one of the most valuable and beautiful mineral collections in the world. To this it is hoped that important additions will be made as soon as the necessary space for their display can be secured.

Mr. Irelan was succeeded as State Mineralogist at the expiration of his term by J. J. Crawford, who was appointed by Governor Markham in February 1893, and Mr. Crawford was succeeded in turn by A. S. Cooper, who was appointed by Governor Budd in 1897. Each of these gentlemen served about four years through their respective terms of office, each doing his share in the upbuilding of the Mining Bureau and in placing the ever increasing importance of the mineral industry of California before the world through a series of carefully prepared reports and bulletins. These documents were issued by the thousands and have been sent to those interested in the industry, to every part of the world. Few official reports are more eagerly sought than those of the State Mining Bureau of California.

Mr. Cooper was succeeded at the expiration of his term of office by Lewis E. Aubury, who was appointed by Governor Gage, April 6, 1901, and continued in office for nearly 11 years, being succeeded by William H. Storms, December 1, 1911. During his administration Mr. Aubury issued numerous bulletins on the mineral resources of the state, which have been distributed in the same manner as those of his predecessors, although during Mr. Aubury's term of office, the legislature passed a law, March 10, 1903,

\*Read before the California Miners' Association.

authorizing the board of trustees of the State Mining Bureau to fix a price on all publications issued by the State Mining Bureau, the money derived from the sale of such publications being used as a revolving printing and publishing fund for the publication of other reports, bulletins, and maps.

The main purpose of the State Mining Bureau is not only to collect and publish statistical data of the mineral industry of the state, as required by law, but to aid in every possible legitimate way the development of the mineral resources of California and to invite the attention of foreign as well as local capital to the vast possibilities of the state in the development of its mines, quarries, and mineral deposits. The mineral production of California for the year 1911 shows a total of \$87,497,879. This figure does not include asphalt, manufactured from crude petroleum, and which alone amounts to \$2,250,000; nor does it include the kerosene, gasoline, benzine, and other light products which result from the fractional distillation of petroleum. These products of crude petroleum, if included, would increase the total to at least \$95,000,000. No natural asphalt is produced in California.

Of the vast total of \$87,497,879, petroleum constitutes nearly one-half, having been \$40,552,088. Following this is the gold production, which was \$19,738,908. The silver production, which in 1910 was nearly \$1,000,000, was somewhat less in 1911, being \$673,336, the difference being due wholly to the reduced copper output, which was seriously curtailed by the court decisions that closed several smelters for a time during the year. The third substance in point of value of production was cement, amounting to \$9,085,625. These figures, as compared with those of a decade ago (1901), when cement manufactured in California was valued at \$159,842, shows to what large proportions this industry has grown within a very few years. Copper production, which in 1910 was \$6,680,641, fell to \$4,604,753. This heavy decrease was due, as previously stated, to the enjoining of several smelters in Shasta county, owing to damage resulting from fume. Much effort is being devoted to the study of fume control, and when a satisfactory settlement is reached the copper industry in California should advance at an astounding rate, for there still remain large copper deposits as yet scarcely more than prospected in a superficial manner. These copper deposits are found in numerous localities, in the northern counties, in the Sierra Nevada, and even in the Coast Range of mountains.

The value of crushed rock produced in 1911 was \$3,610,357, as compared with \$2,777,690 in 1910. The brick industry in 1911, including all kinds, showed an output of \$2,638,121, as against \$2,934,731 for 1910. The falling off in the use, and consequently the price, of brick is due to the substitution of concrete for brick in building. This also accounts in a great measure for the large increase in the production of cement.

In 1911 there were produced 41 different minerals. These were worked in 55 of the 58 counties of the state. But three counties of the entire state failed to respond to letters of inquiry sent out by the statistical department of the Mining Bureau, these being Alpine, Sutter, and Yolo. It is known that there are mineral deposits or mines in each of these three counties, but they appear to have been idle during 1911. The complete total of \$87,497,879 actual production is the largest ever made by the mineral industry in the history of the state. As the population of the state increases and as its commerce expands, the demand for its natural mineral products and for the various articles manufactured from them must be augmented in at least a corresponding ratio, if not exceed such expansion and development, for the reason that California will export large quantities of her mineral products. It is confidently believed, therefore, that the value of California's mineral output will hereafter show an increase rather than otherwise, particularly in the line of structural materials.

The gold mining industry is one that will probably keep up its present production for years to come. There are many gold properties, both veins and ancient channels, still undeveloped which promise to yield handsomely upon de-

velopment and equipment with suitable mining and metallurgical machinery. Ores rich in gold, at present considered base or refractory, will in time be treated as readily as those now known as free-milling. The copper industry must assume far greater importance as soon as smelter-fume difficulty is overcome, and indications are that this fortunate condition will soon be reached. The iron industry in this state is in its infancy. Splendid pig iron has been made in the electric furnace in Shasta county from the magnetite that is so abundant there. There are immense masses of iron ore in various portions of the state, and these, in the coming years, will form the basis of a great industry. The production of structural material must annually increase as these enter so largely in the upbuilding of our ever-growing cities. Besides these there are other mineral resources which will show an increasingly greater production in the coming years.

The only institution in California that officially represents the great mineral industry of the state is the State Mining Bureau. The production of California mineral in 1911 was \$87,497,879, clearly indicating it to be one of the most important industries of the state. Notwithstanding this large output of minerals of almost every description, I am confident that the Mining Bureau, if properly supported by legislative appropriation, will be directly instrumental in greatly increasing this large total, by directing attention to the undeveloped as well as the developed mineral deposits of the state. Almost unlimited money is available for investment in the various branches of the mineral industry, if only the attention of capital can be properly called to the many existing opportunities.

Nearly every state in the Union has a department of geology or mining, or both, that issues annual reports, in addition to bulletins on special subjects. During the first ten years of the existence of the Mining Bureau, general reports were issued annually, followed by biennial reports in 1892-1894 and 1896. Since the latter date there has been no general report on the mineral industry. The effect of the discontinuance of the general report has been to deprive the people of California of any definite or official statement of the progress of the mineral industry in the state. The Mining Bureau is daily in receipt of questions, not only from the citizens of this state, but from other states and foreign countries as well, seeking information that the Mining Bureau is supposed to give. Up-to-date information in many instances is not available for the reason that the Mining Bureau has been unable for sixteen years to collect the necessary data, simply for lack of the money required to employ competent field-men to visit the counties of the state and collect from the proper sources the available data.

In view of the approaching exposition in San Francisco in 1915, it is particularly desirable that California now take the necessary steps to properly present to the world the splendid commercial opportunities which her vast mineral resources afford. The best possible channel through which to call attention to our mineral industry and its advantages for investment is the State Mining Bureau. The constant demand for the publications of the Mining Bureau and the fact that so few of them are now available (notwithstanding that for the past nine years the Bureau publications have been sold instead of distributed gratuitously as formerly), shows better than anything else the importance that the public attaches to the reports and bulletins of this state institution. To be of the greatest value these reports must be brought up to date.

Fully realizing the fact to be as above set forth, I have made an estimate of the needs of the State Mining Bureau for the sixty-fifth and sixty-sixth fiscal years. It is the intention to take up the compilation of a general report which will treat particularly of the gold-mining industry of the state, and to generally review the existing conditions of the mineral industry in California. It is also planned to undertake special studies of the iron deposits of the state and to publish the results of such investigation in the form of a bulletin. Also a bulletin on the metallurgy of gold, another on mining methods, and a third on the Mother Lode.

which is each year becoming of greater importance. It is also requested that a special study of the undeveloped ancient gold-bearing rivers of the northern part of Sierra and Nevada counties be undertaken, as it is believed such studies will prove to be of great value in furthering the development of mining there. The need of a proper display of California mineral wealth at the great Panama-Pacific Exposition no Californian will question. In order to make the most creditable display, money is necessary, and for this purpose alone the sum of \$25,000 is asked of the legislature.

It is now many years since the State Mining Bureau has been so well equipped in the personnel of its staff as it is at present. The department of determinative mineralogy is a most important branch of the work of the Mining Bureau. This department has for nearly fourteen years been in the hands of E. B. Preston, who has now been connected with the Bureau, as field assistant and as determinative mineralogist, since 1889. The fact that Mr. Preston has made in the past fourteen years over 30,000 determinations of the rocks, ores, and minerals of California, keeping an official record, and that in addition to these, he has made determinations of not less than 10,000 other samples submitted in person by visitors at the Mining Bureau, indicates the extent of the popularity and usefulness of this branch of the Bureau's work. Mr. Preston is a graduate of the school of mines at Freiberg and is widely known throughout California.

The library of the State Mining Bureau is under the direction of Walter W. Bradley, a graduate of the College of Mining of the University of California. The statistical work is in the hands of E. S. Boalich, who was formerly employed in the statistical branch of the United States Geological Survey. Mr. Boalich is also a graduate of the College of Mining of the University of California. Fred L. Lowell, who has been appointed curator of the mineral collection of the State Mining Bureau, is well qualified for the duties of that office. He, too, is from the University of California. The fact that the staff of the State Mineralogist is composed entirely of mining engineers of experience is of great advantage, as the members are each competent to perform the duties of the others. W. W. Thayer has been connected with the Mining Bureau since early in 1906. In his care are the accounts of the Bureau, and he also has general supervision of the structural exhibit now being placed in the corridor leading to the museum. In this are exhibited some of the best of the state's building stones and manufactured structural materials.

THE following estimates of appropriations necessary for the support of the State Mining Bureau have been made by W. H. Storms, State Mineralogist, and approved by the board of trustees, covering the sixty-fifth and sixty-sixth fiscal years, a period ending June 30, 1915:

For salary of state mineralogist.....	\$6,000
For the support of the State Mining Bureau, including salaries .....	40,000
For a geological survey and preparation of a general report—	
Six field men, salaries.....	\$21,600
Six field men, expenses.....	17,400
	39,000
Special work on Mother Lode.....	2,000
Special work on iron deposits.....	2,500
Special work on metallurgy .....	2,000
Special work on mining methods.....	2,500
Special work on ancient channels.....	6,000
Panama-Pacific Exposition .....	25,000
For printing, binding, ruling, and all other work performed and materials furnished by the State Printing Office .....	10,000
Total .....	\$135,000

A 15-stamp mill is to be erected at the Hillside mine, in the Mud Springs district, California. An adit has been driven 400 ft., and a fair quantity of ore opened.

## Explosion-Proof Motors for Mines

The United States Bureau of Mines has recently published the results of an investigation of explosion-proof motors by H. H. Clark, who has charge of the electrical investigations of the Bureau. The term 'explosion-proof', as applied to an electric motor, refers to a motor inclosed by a casing so constructed that an explosion of a mixture of mine gas (methane) and air within the casing will not ignite a mixture of the same gas surrounding the motor. There are two classes of motors so constructed: first, a totally enclosed class built strong enough to withstand high internal pressures and so designed that the efficiency of the covers can be satisfactorily maintained; second, a class provided with relief openings or valves designed to relieve the pressure of an explosion within the motor casing and to cool any products of combustion discharged through the valves. A satisfactory motor of the first class is much more expensive to build than an equally safe motor of the second class. For this reason attempts to make motors explosion-proof have been confined chiefly to motors of the second class.

The function of explosion-proof devices for electric motors is to reduce the temperature of any flames that may be discharged from the motor casing below the ignition point of methane. Various plans have been proposed and developed for removing heat from the products of explosion. The principle of the Davy safety lamp has been the basis of most of the protective devices. The application of this principle consists in causing the discharged gases to pass over or through metallic plates or screens which by conduction remove the heat from the gases. In some types of devices the cooling effect of expansion is also utilized.

## Water Supply of the Rand

Water supply of important mining districts is always of interest, and the following notes are from the seventh annual report of the Rand Water Board: The total yield from wells and bore-holes during the year ended March 31, 1912, was 2,994,525,448 gal. When the new Springs and Zuurbeek schemes are completed there should be available 10,700,000 gal. per day. For the supply from the Springs mines, the Victoria Falls & Transvaal Power Co. is supplying electric power at 1c. per unit + \$48 per kilowatt per annum, which brings the total cost to 1.24c. per unit. This scheme will cost \$270,000, and there will be 36,740 ft. of 16-in.  $\frac{3}{16}$ -in. thick pipe from the Springs pumping station to the Leeuwpoort reservoir; 15,080 ft. of 16-in.  $\frac{1}{4}$ -in. thick; and 6013 ft. of 13-in.  $\frac{3}{16}$ -in. thick pipe from north and south shafts to the pumping station; and 9746 ft. of 6-in. 10-gauge pipe between the north shaft and the Springs service reservoir. During the year the total supply was:

District.	Total per annum sold, gal.	Daily average, gal.	No. of meters.
Johannesburg Municipality.	964,104,350	2,634,165	72
Germiston Municipality ....	133,407,700	364,502	19
Rodepoort-Maraiburg Municipality .....	15,634,300	42,717	9
Spring's Municipality .....	16,343,900	44,655	3
Benoni Municipality .....	20,606,000	56,300	10

# Graphic Representation of Oilfield Structure

By ALEXANDER J. HEINDL

Two methods, one to a certain extent dependent upon the other, have been used to represent underground structure in the oilfields. These are: (1) vertical sections, determined by plotting the logs of several wells along certain lines; (2) underground contours, representing the surface of oil or water-sands by means of contour lines. In addition, there is the method of stereographic projection, to which particular attention is directed in this paper. Stereographic projection for diagrammatic purposes in mining work has, in several cases, proved to be useful, but its practical application to detailed underground studies in oil work is new.

## LOGS AND RECORDS

Log of a characteristic California well is shown below.

Depth		Feet.	Formation.
from	to		
0	455	455	sand and gravel
455	475	20	blue clay
475	505	30	sand shale (sulphur water at 490 ft.)
505	720	215	sand
720	735	15	blue clay
735	742	7	water-sand, water
742	745	3	shell; very hard
745	755	10	sandstone
755	760	5	soft clay
760	795	35	water-sand, water
795	799	4	clay
799	801	2	shell
801	817	16	blue shale with sand
817	825	8	blue clay
825	840	15	blue shale
840	850	10	clay
850	855	5	tar sand
855	860	5	blue shale
860	863	3	shell
863	872	9	tar sand
872	880	8	sand
880	886	6	tar sand
886	894	8	blue shale
894	901	7	clay
901	959	58	blue shale (hard shell at 915 to 930 ft.)
959	981	22	blue clay, gumbo
981	984	3	shell
984	1022	38	blue shale
1022	1024	2	oil-sand
1024	1034	10	shale showing oil
1034	1084	50	blue shale
1084	1099	15	brown shale
1099	1104	5	oil-sand
1104	1114	10	brown shale
1114	1138	24	oil-sand
1138	1209	71	brown shale
1209	1211	2	oil-sand
1211	1219	8	brown shale
1219	1234	15	sandy shale

		Feet.	
Total depth drilled.....		1235

Iron heaving plug 1 ft. to.....		1225	
Bridge on iron plug to.....		1223	

### Casing:

Size, in.	Ft.	In.	Size, in.	Ft.	In.
12½ .....	588	6	8 .....	1035	0
10 .....	895	0	6 .....	1234	0

### Perforated:

1104 ft. 4 in. to 1218 ft. 5 in. Size of perforation, ¾ by ¾ in. Three rows each joint.

The discrimination made by the driller between shale and clay is sometimes justified by the inspection of the drillings. As a rule, however, it depends upon his judgment, and the judgment of drillers is not uniform. Gumbo is a field term for soft sticky clay. Heaving sand is a soft sand, frequently carrying water, which rises up in the casing and often causes difficulties in drilling. The water of the water-sand is sometimes saturated with hydrogen sulphide, and in such a case it is labeled as 'sulphur sand.' The 'tar sand' carries variable amounts of heavy oil, forming imperceptible gradations from sandy shale to poor oil-sand. These formations frequently change in character within short distances; they may vary considerably in thickness or even 'finger out' entirely. Not infrequently logs of two or more wells within two or three hundred feet of each other will differ to such extent as to make the correlation of their components impossible.

Besides the personal equation mentioned above, the methods of drilling are, no doubt, responsible in part for this inconsistency. In case the usual standard drilling machine is used, a 'screw' of 5-ft. length is drilled before the material is bailed out for inspection. If more than one kind of rock has been penetrated, their relative thicknesses have to be estimated by the action of the drill, aided by the amounts of different material brought up in the bailer. With the rotary or the standard circulator, the determination depends upon the inspection of the sediment that is being continually brought out in suspension with the drilling mud. Frequently this determination is practically impossible. There are, however, characteristic strata occasionally found that are persistent over large areas in the field, and they form good material for correlation of well records. Such persistent beds in California are usually clays or limey strata having characteristic color. The fossil contents, as sometimes revealed in the drillings, often aid in similar correlation.

Fig. 1 is a graphic representation of the above log. In practice these logs are usually drawn to a scale of 1 in. representing 100 ft. Several of these graphic logs, when placed side by side, with the horizontal and vertical distances corresponding to those of the respective wells in the field, form what is known as a vertical section or profile. While the vertical section gives an excellent idea of the structural conditions along a particular line, it fails to interpret the structure of that part of the field, simply because a section is drawn in two dimensions, whereas the actual relation of the formations in the field would require the introduction of a third dimension.

## UNDERGROUND CONTOURS

Fig. 2 is an underground contour map. In determining the position of the contour lines it is necessary to make numerous sections across the field in order to correlate the various strata, such as the oil-sands and water-sands, shown on the well logs. The elevation, relative to sea-level or to some arbitrary bench mark, of the top of the persistent strata (oil-sand) is then determined for each well, and the result plotted on a map, the connecting points of equal elevation with contour lines. On the same map the surface contours are indicated. The surface and underground contours are usually drawn in different colors, or one is a solid and the other a dotted line. Care should be exercised in correlation when several oil-sands, one above the other, are found in the field. Usually only the most persistent and widespread oil-sand is mapped.

When the surface and underground contours are plotted the depth of the stratum at any point can be determined by the simple sum or difference of the elevations represented by the two contours, depending upon whether the elevation of the stratum is negative or positive. For example, if the surface elevation of a point is 1000 ft. and

\*Published with the permission of the consulting geologist of the Southern Pacific Company.

the stratum -100 ft., the depth below the surface is 1100 ft. If, on the other hand, the elevation of the stratum is +75 ft., then the depth will be 925 ft. The underground contour maps, at best, can show only one or two of the underground strata. If several lines representing

of the upper plane is arbitrarily taken as 30°. It has been found, as a result of experiments, that for oilfields the use of two scales is very convenient: one for all horizontal dimensions (1 in.=400 ft.), and the other for vertical (1 in.=200 ft.). Using these two scales, there appears to be a practical limit to the area mapped. Each separate drawing can conveniently show a block of ground whose surface area is equal to about one square mile, while the vertical extent is usually limited by the lowest oil-sand, not exceeding, in general, 3500 ft. below the surface. Following is a method of constructing such a 'block':

An arbitrary plane has to be chosen somewhat above the highest surface feature, on which the position of all wells is to be indicated, remembering that if a well is, for example, 180 ft. south and 300 ft. west from the northeast corner, the position would be found by measuring these

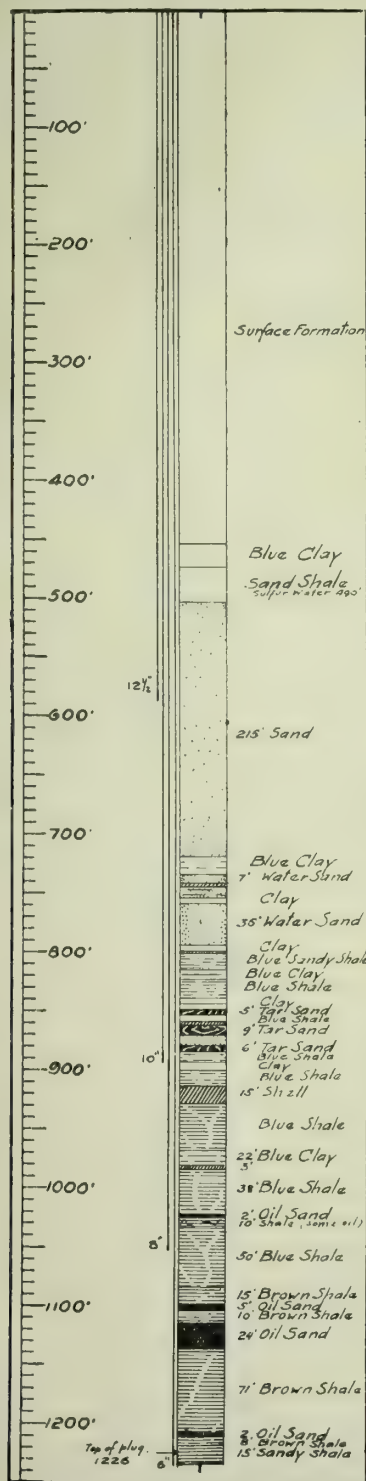

FIG. 1.

various strata are plotted on one map, the result is complex and difficult to use.

#### STEREOGRAPHIC PROJECTION

The stereographic projection has the advantage over the other two described methods in that all the conditions of the wells under an area of considerable size can, in the one drawing, be brought before the eye. The isometric perspective, which is used in this case, shows a cube as if it were looked upon from a side, somewhat above the upper plane. The foreshortening is omitted, so as to have the length of each edge in the cube equal; the acute angle

FIG. 2.

lengths true to scale in directions parallel to the border lines of the reference plane (Fig. 3). These points, however, do not represent the collars of wells as it would be in an ordinary plan; they are only the points of intersection of the axis of each well with the reference plane.

FIG. 3.

In order to find the position of the collar, a vertical line is drawn through the point of intersection, and the difference between the elevation of the well and that of the reference plane is measured downward from the trace. In Fig. 3 the elevation of the well indicated is 538.5 ft., while the elevation of the plane is taken as 600 ft. above sea-level.

If several collars are defined in similar manner, a general idea of the topography of the area is obtained, which will be made clearer when the intersection lines between

the surface and the border planes are drawn (see Fig. 3). A much more satisfactory result can be obtained if a topographic map of the area is available and the contour lines are transferred on the diagram. The log of each well is then plotted from the collar downward, using different

to give an approximate idea of the form of the oil-bearing zone. Fig. 4 shows the method of plotting. For the sake of brevity, the oil-sand in each well is indicated as a point, which might be taken as the upper limit in the well. Imagine a vertical plane drawn through two wells. A line

FIG. 4. STEREOGRAPHIC PROJECTION OF A CALIFORNIA OIL SAND.

colors or symbols for different formations of interest, such as shale, tar-sand, water-sand, or oil-sand.

Considerable difficulty is usually found in the correlation of various formations, except the oil-sands. The latter fit usually into a continuous blanket, and the exact determination of the form of each is the aim of the method described.

At least three wells not in a straight line are required

drawn through points marking the upper limit of the sand will lie also in a plane which, prolonged, will intersect the two border planes at points which will be on the intersection lines of the plane with the sides of the block. Similarly, other vertical planes may be used to define the points on the border planes, and by connecting these points with straight lines the outside rim of the oil-sand may be found. This is usually shown by a full line on the

front planes and dotted on the back planes. Evidently, the drawing of any of the vertical planes is reduced to the drawing of three lines, which simplifies the whole construction.

As mentioned, the *plane* which passes through the first three oil-sands is only a first approximation to the actual form of the oil blanket, and each additional well will modify its form and bring it closer to the existing configuration. From six to ten wells, scattered along the border lines of a section, will usually give good initial information about the internal conditions of this section.

Wells outside, within a certain distance from the section mapped, furnish just as valuable data as those inside, the method of plotting being identical with the one previously mentioned. In several instances a section was plotted, guided by the outside wells only. Fig. 4 is a copy of an office drawing of similar kind.

A further plasticity is added to the stereogram when contour lines are drawn on the surface of the oil-sand. This is accomplished by drawing horizontal planes at an interval of 100 ft., referred to the sea-level, and observing where each plane intersects the oil zone. The oil-sand contours of drawing Fig. 2 were originally drawn on the stereogram and afterward transferred to a smaller scale drawing.

It might happen that the oil-sand has such dip and strike that, when plotted under standard conditions—that is, with the east-west line parallel to the observer—the form of the oil surface will approach a line, because of the fact that it lies in the plane of sight. This is easily avoided by turning the block 90° around its vertical axis, making the north-south line parallel to the observer.

It is to be noted that such a stereogram is a drawing in the technical sense of the work; that is, everything that is shown on it can be measured and read to scale. The direct reading of distances (to scale) between two points can be made in the three main directions only; to read a distance between any two points, the line connecting these two points has to be rotated (around a vertical axis) until it comes to a position parallel to the front plane. The same thing holds true for the angles of dip.

## Potash Explorations in Nevada

The results of explorations for salines in Silver Peak marsh, Nevada, recently made by the U. S. Geological Survey, have been published in a short report by R. B. Dole, of the Survey, as Bulletin 530-R, an advance chapter from Bulletin 530. Silver Peak marsh is a salt *playa* or dried-up lake, of prehistoric origin, about 20 miles west of Goldfield and 25 miles southwest of Tonopah, two well known mining centres of Nevada. The exploration was made for the purpose of ascertaining whether deposits of potash salts in commercial quantities lie within easy reach of the surface. No extensive beds of such salts were discovered, although the salts in certain samples of brine contain as much as 3.43 and 3.80% of potash ( $K_2O$ ). Drill-holes were sunk at several points in the old lake bed by means of a small portable drilling outfit, operated by a burro, the borings being carried to a depth of about 50 feet.

Practically the entire surface of the *playa*, 32 square miles, is covered with salt that averages in depth about one-quarter of an inch. The upper muds, averaging probably 10 ft. thick, contain not less than 2% of salt. It is estimated that not less than 15 square miles of the northeastern part contains a 10-ft. saline bed, of which at least 60% is salt. It is calculated from these moderate estimates that 15,000,000 tons of salt lies within 40 ft. of the surface. The high rate of evaporation, which would permit solar concentration of brines, the absence of long-continued rainfall to interfere with operations, the nearness of a railroad, and more especially the high degree of purity of the product as indicated by analyses of the brines are extremely favorable features in regard to the possibility of utilizing these deposits. Salt is now being produced on a small scale by Frank Porter, of Silver Peak, who states that about 150 tons has been sacked and sold in three years.

## Mining in Burma

That mining in Burma is receiving increasing attention is shown by the fact that during the fiscal year 1910-11 new applications for prospecting licenses numbered 1224, as against 262 in the preceding year. Applications numbering 738 were received for prospecting in the Tavoy district, where large deposits of tungsten and tin are known to exist.

The production of the principal minerals in Burma during the calendar year 1911 is given in the following table (ton = 2240 lb.; hundredweight = 112 pounds):

Minerals.	Quantity.	Value.
Rubies, carats .....	222,968	\$316,495
Lead (slag) tons .....	31,954	331,926
Lead (pure), tons .....	13,259	299,029
Tungsten ore, hundredweight .....	17,765	297,634
Gold, ounces .....	6,422	118,590
Tin, tons .....	88	75,609
Jade, hundredweight .....	2,062	55,908
Silver, ounces .....	103,850	55,308
Silver-lead ore, tons .....	3,218	23,403
Sapphires, carats .....	17,269	9,146
Spinel, carats .....	47,976	3,171
Galena, tons .....	189	3,495
Iron ore, tons .....	20,995	2,484
Copper ore, tons .....	159	2,400
Platinum, ounces .....	38	1,188
Amber, hundredweight .....	13	649
Total .....		\$1,596,426

The Ruby Mines Co. of Mogok, Upper Burma, experienced a bad year, the value of its output being given as only \$316,495. Low prices for rubies in the London market were responsible for the small production. According to the census of 1911, this company employed 1393 workers. Most of the lead and silver obtained in Burma during 1911 was produced by the Burma Mines Co., Ltd., at the Bawdwin mines in Tawngpeng, northern Shan States. The quantity of silver-lead ore and lead slag obtained in 1911 was considerably larger than the production of 1910, but the value of pure lead obtained was only \$299,020, as compared with \$773,851 in the preceding year, while the value of pure silver was nearly three times as great as that obtained in 1910. The Burma Mines Co., Ltd., has a lead smelter at Mandalay employing 536 persons.

There were, in 1911, 17 tin and tungsten mines in operation in Burma, 11 in Tavoy, 5 in Mergui, and 1 in the southern Shan States, employing 1935 persons, mostly in the tungsten mines. Although prospecting on modern lines for tungsten in Burma commenced only within the past two years, great development has taken place and the prospects are extremely good. Ore has been discovered in workable quantities in the Tavoy and Mergui districts of Lower Burma and in the southern Shan States. The industry in the last named region is greatly handicapped by want of adequate means of transport. The mines are about 300 miles from Toung-gu, in the southern Shan States, where there are no railways or cheap means of communication. The production of tungsten in Burma in 1911 amounted to 995 short tons, but it is not stated whether this is ore or concentrate. This would seem to indicate that as the industry becomes more developed, Burma will become one of the world's largest producers. The Burma Gold Dredging Co. produces most of the gold found in Burma. This company has four dredges of Australian manufacture working in the Irrawaddy river, near Myitkyina, in Upper Burma.—*Daily Consular and Trade Reports*.

THE Hedley Gold Mining Co. has declared the regular dividend of 3c. per share, and a special one of 12c., a total of \$180,000, making the 1912 distribution of \$360,000. The Utica mine is on Kaslo creek, in the Ainsworth district, and Spokane capital is interested. Since July 1, when operations were resumed at the property, gross earnings have been \$40,000. The ore contains silver, lead, and zinc.

## Metallurgy at Tonopah

By M. W. VON BERNEWITZ

Simplicity of operation seems to be the key-note of treatment methods at this interesting mining centre, having been brought to such a point by much intelligent experimenting. To obtain an average of 93% extraction at a cost of, say, \$3 from ores carrying 30 oz. of silver and a few grains of gold per ton is good work, and not long ago would have been termed impossible, especially in such a situation as Tonopah.

Tonopah ores may be described as consisting of fine granular quartz (the silica averaging perhaps 80%), without noticeable quantities of sulphides, poor in the base metals, and containing disseminated silver minerals, and gold. The primary metallic minerals are silver sulphides, principally polybasite, stephanite, and argentite, with occasional pyrite, chalcopyrite, galena, and blende. Silver selenide also occurs. Silver chloride, bromides, and iodides occur, mainly at least, as secondary minerals. Silver also appears in the metallic state. Gold occurs in the proportion to silver of about 1 to 100 by weight, and has been seen in the free state.

In Tonopah there are five mills—the Belmont, Extension, MacNamara, Montana, and West End—while at Millers, 12 miles north, are the Belmont and Tonopah mills, ore being shipped to these at a cost of 70c. per ton. In nearly every case gyratory crushers are used for breaking ore as it comes from the mines, the procedure being to crush first in a large crusher, up to the No. 7½ type K Gates size, pass through revolving trommels, the oversize being again reduced in No. 3 size gyratories, the final product for the stamps being about 1¼ in. Sorting is done at the Belmont and MacNamara mills; at the former on a pan conveyor from which 15% is rejected; and at the latter on a 30-in. rubber belt, from which 6% is sorted out. From the crushing department, the ore is taken to mill bins by 20-in. belt conveyors, or bucket elevators, and distributed by the usual automatic devices.

Tonopah millmen have not been troubled with the heavy-stamp mania, although the ore is fairly hard, and the 320 stamps at work vary between 1100 lb. at the Montana to 1400 at the MacNamara, the latter having probably the toughest ore in the district. Several different methods of driving stamps by motors are to be noticed, and will be separately described later. Foundations are usually of concrete, and give satisfaction. The new Belmont mill has sheet-lead under its mortars, but this is being replaced with rubber. There are no high-speed stamps, the average being perhaps 103 drops per minute with 7-in. drop. Both square-mesh and ton-eap screens are used, sizes varying from 6 to 20 mesh, and the stamp-duty is from 4 to 8 tons per day. The Challenge feeder is now a simple contrivance compared with the original, and may be described as a double monkey-wrench grab, which turns the gear and feed plate. There is no amalgamation at Tonopah, nor is it necessary on this class of ore. Crushing is done in weak and warm (from 50 to 80°F.) cyanide solutions, so the ore is in contact with solution from the stamps to filtration. This is necessary as well as the heating, which, although somewhat expensive, quickens the solution and accelerates the dissolving action. Solutions are usually heated to about 95°, and in one case 120°, by live steam introduced in the agitators.

The practice of using hot solutions is briefly as follows: At the new Belmont mill the temperature at the stamps is from 60 to 70°F., and at the Pachuca agitators exhaust steam from the mill air-compressor is fed in, increasing it from 90 to 100°. In the *Mining and Scientific Press* of January 27, 1912, A. H. Jones, metallurgist at this plant, gave some valuable data on this subject. On an ore carrying 0.05 oz. of gold and 18.2 oz. of silver per ton, 60 hours' agitation with both 60 and 90° solutions, the tailing averaged 0.0175 and 3.45, and 0.0125 and 1.90 oz. respectively. Tests on 48 and 69 hours at similar temperatures gave as marked results. Besides the effect on extraction,

the hot solutions flowing through the mill kept the whole place at a good working temperature. At the Montana-Tonopah, ore is crushed in 50 to 60° solution, which is increased to 110° at the Hendryx agitators by live steam. It is found also that the heat aids settling. There is a marked decrease in extraction without hot solutions.

The MacNamara mill recently had experience with cold solutions, owing to an enforced shut-down for two days. The Trent agitators are usually kept at from 115 to 120° by live steam and it was found that it took several days to heat everything again, in the meantime the time of agitation had to be increased and extraction fell off considerably. Heat is necessary in the summer, but less steam is used. The cost is about 30c. per ton treated. The Extension ore is crushed in 80° solution, and live steam is added to the Trent agitators as soon as possible, making the temperature up to 120°. It was found that this was better than 90° and extraction has improved 1.5 to 2% during the past few months, it being 94.5% at present. About 2100 tons of solution is circulating in the mill, and it takes 7 days to heat this if it should get cold, meanwhile extraction falls off.

Cost of heating is 18c. per ton. It has been found at the Belmont mill, at Millers, that in passing through a tube-mill the temperature of the solutions increases, presumably by the grinding action of the pebbles, mill liners, and ore particles. A test taken while I was there showed feed temperature at 65°, and discharge 70°. In the *Mining and Scientific Press* of February 24, 1912, Noel Cunningham, at Millers, contributed the results of some experiments, proving that laboratory work had shown greatly improved results from hot solution. At another plant treating Tonopah ore, crushing is done in 76 to 80° solution, increased to 95° in the agitators by live steam in coils. Recent tests showed a saving of 24 to 32c. at a cost of 11c. per ton. The same temperature is kept up in summer and winter. At the Mexican mill, Virginia City, solution is heated to about 96°, at a cost of 12c. per ton, results being improved by this system, the average extraction being 92 per cent.

It is to be hoped that millmen in Cobalt, Mexico, and Waihi will give their experience with heating solutions. When I was with the Waihi company in 1898, heating was tried, but I kept no data. It may be interesting to mention that, at Kalgoorlie, treating an ore containing practically no silver, some argument was raised as to the benefit of hot solutions in treatment. The heating there is not intentional, as at Tonopah, but comes about through the hot roasted ore being mixed with solution, bringing it up to nearly 200°. The discussion resolved into whether by cooling prior to mixing there would be less consumption of cyanide, and less trouble with sulphates being deposited in launders, pipes, and pans, or whether there were benefits derived from the resulting hot pulp. The Associated, Associated Northern, and Kalgurli, more particularly, found that there was no appreciable decomposition, and up to 50% of the gold was dissolved at that point; while the Great Boulder, Perseverance, and South Kalgurli preferred to cool the ore before mixing.

Tonopah ores carry as much as 3% of pyrite, but concentration is not always employed, it being done only at the Belmont, Montana, Tonopah, and West End. It would seem that if the grade of the ore and percentage of mineral is not too high, tables are not necessary, and this varies from time to time in the various plants. At any rate, a very close saving is not attempted. The Extension company dispensed with their Deister tables, selling them to the West End. The Belmont, Montana, and Tonopah use Wilfley tables. Concentrate is collected, steam dried in large trays, sacked, and shipped to smelters. Freight and treatment cost nearly \$70 per ton. It seems a pity that such a high cost is necessary, and that the product could not be handled locally by some central plant, which would treat the combined output at about \$10 per ton.

All-sliming is the standard method, with the exception of the Tonopah mill at Millers, where three products are made; concentrate, sand, and slime. At this plant reduction is by stamps, and Chilean and Huntington mills; while at Tonopah the procedure is as follows. The pulp from the stamps is fed into Dorr duplex classifiers making 12 strokes per minute, from which slime overflows and coarse material is fed into tube-mills by means of a special feed. Discharge from these is elevated to the Dorr classifiers, and a further classification takes place, further grinding in the tube-mill, and so on. The only product which escapes to the slime plant is from the Dorr machines. This is termed the closed-circuit system, and is a good one. At the West End, the Dorr classifier discharge is:

100 mesh .....	%
150 " .....	99
200 " .....	93
200 " .....	89

There are 16 tube-mills in the district, varying from 5 by

DORR CLASSIFIER, TUBE-MILL, CLOSED CIRCUIT.

18 ft. to 5 by 22 ft., revolving at about 26 r.p.m. Usually the locally-made smooth liners give good results. These are  $\frac{1}{2}$  in. thicker at the feed than discharge end, and last over nine months. At the Extension mill, there are two classifiers and two tube-mills in the closed-circuit, arranged thus in series: coarse pulp from No. 1 classifier is fed into No. 1 tube-mill which is fitted with ribbed liners, and is discharged to a bucket elevator, which in turn lifts the partly-ground material to No. 2 classifier which feeds No. 2 tube-mill fitted with smooth liners, the product being returned to the No. 2 classifier. The consumption of pebbles is 4.5 lb. per ton milled. It is claimed that ribbed liners are better on coarse pulp than smooth ones, and the latter can do the final grinding better. The ribs pick up pebbles and toss them about more in the mill, this giving extra impact for coarse material which is not necessary for the fine. At the Goldfield Consolidated mill this is also the practice. Pebbles remain in a better rounded shape with ribbed than when used with smooth liners, which tend to produce flat surfaces. When discussing the action of various crushing machines in the *Mining and Scientific Press* of December 10, 1910, I mentioned the corrugated liners used at Kalgoorlie affording a long life and extra grinding results. Some of the Tonopah mills find that it is not necessary to get an extremely fine product, the pulp being 73 to 89% through 200 mesh.

Various types of thickeners or dewaterers are in use, the practice being to allow the clear solution to overflow and decant off as much as possible for battery storage. When it gets too high in gold content it is decanted to the tank for precipitation. As at many other mining centres there is quite a difference of opinion regarding the efficiency of agitators, the Trent being used at the MacNamara, Montana, and West End; the Hendryx at the Montana;

Pachuca tanks at the new Belmont mill; and ordinary mechanical agitators and air-lifts at the Belmont and Tonopah at Millers, these being in series at the Belmont plant. Centrifugal pumps and air at about 20 lb. pressure are used for the Trent system; and better results are obtained if pulp is drawn off near the top of a full vat and pumped through the arms as usual. Agitation proceeds for upwards of 48 hours. At the new Belmont mill, slime is first agitated in six Pachuca tanks, and from these it is elevated to Dorr thickeners by an air-lift, prior to going to another set of six Pachucas, making a total of 48 hours' agitation, the idea being to get rid of as much valuable solution as possible before sending slime to the filter-plant. Cyanide and lead acetate are added to the agitators, the former being from 2 to 5 lb. solution, while regular addition of the acetate is found necessary at all mills. Lime is usually slacked, and added to the tube-mill feed. Consumption of chemicals at the Extension is as follows:

	lb.
Lead acetate, per ton.....	0.9
Cyanide, per ton.....	2.5
Lime, per ton .....	3.5

Agitated slime is drawn off to stock-tanks, which serve the purpose of storage from agitators and excess from

NEW MILL, BELMONT COMPANY.

filter-plants. The latter have little of special note about them, they being of the ordinary stationary leaf type which have been described so often in technical papers.

Zinc-dust precipitation is used at the new Belmont and Montana mills, and zinc shavings at the Belmont, Extension, MacNamara, Tonopah, and West End. Methods of dealing with precipitate vary somewhat. At the new Belmont precipitate is dried, mixed with 5% of borax and smelted in double-compartment, oil-fired Rockwell furnaces, lined with carborundum, kaolin, and water glass. At the Extension it is dried, fluxed, and smelted in oil-fired Steele-Harvey tilting furnaces, which contain a No. 250 graphite crucible, while at the Tonopah mill the fine zinc shaving precipitate is incompletely dried, mixed with crude borax which swells up through the mass, and then is smelted in six coke-fired tilting furnaces. Crucibles last from 90 to 130 hours, and are turned once. Tonopah bullion will average 950 fine in silver, and a trifle over 10 in gold, and is sampled by being bored at opposite corners of top and bottom of bars. The bullion is shipped by freight like any other merchandise.

The mills at Tonopah are fortunate in having such a good supply of electric power as is available, and mechanical details are thus much simplified. I do not think there is a single engine in any mill there, also every machine having a motor drive. Chain drives are fast becoming popular, and apparently there is no dissatisfaction with them, once their peculiarities are understood. Such items as motor drives, and elevating pulp will be discussed later. In conclusion, it seems to me that generally the treatment of silver ores at Tonopah has been simplified to a fine point with good results, and is creditable to all concerned. There is not a dismantled mill, nor a badly designed one, nor any built for a mine without ore, to detract from the good work of the district.

## A Self-Filling Measuring Bottle

By O. C. SMITH

In washing a precipitate or residue with a certain volume of liquid, this apparatus is very convenient. By using a small necked flask for the smaller one, this arrangement will discharge to within a couple of drops of a given amount. In fact, this apparatus will fill a 100-c.c. flask to within one drop by exercising a little care. The large flask is placed on the back of the desk out of the way. The rubber tube

AUTOMATIC MEASURING BOTTLE.

*F* is used to supply air. This ends in a tube, *B*, in which there is a slit to serve as a valve. By blowing in *F* water is forced through *C* and *E* into *X* and when this is full, out through *D*. By moving *D* the capacity of the flask can be changed. The stopcock is now turned and air enters through *A* and *E* into *X*. By closing *D* with the thumb *X* is converted into an ordinary wash bottle.—*Jour. Ind. & Eng. Chem.*

## Tempering Copper and Bronze

The production of bronze alloys in one operation and the hardening and tempering of copper are perpetual topics of popular discussion, so that the statements made by Walter Gowland at a recent lecture in London are of interest. Mr. Gowland, besides being a distinguished metallurgist and emeritus professor of the Royal School of Mines, is also an antiquary of note, as is evidenced by the fact that some years ago he was deputed to make the historical examination of Stonehenge. His researches into the history of metallurgy in all parts of the world are elaborate and learned. In his lecture he showed that during the early metal age, and even later, bronze was not obtained by melting metallic copper and tin together, but by the reduction of oxidized copper ores containing cassiterite, or of copper ores to which cassiterite ore was added. It is important that this fact should be recorded, seeing that some modern metallurgists allege that such a process is impossible, and that whenever tin and copper ores are smelted together the tin does not unite with the copper but passes into the slag. These allegations were evidently not founded on experiment, but on erroneous deductions from the methods of smelting in use at the present time.

In order to determine the possibility of producing bronze, Mr. Gowland constructed a simple furnace consisting merely of a hole in the ground. In this he treated a mixture of 15 lb. of malachite, containing 30% copper, and 10 lb. of cassiterite ore containing 20% tin, together with charcoal and limestone. The furnace cavity was filled with charcoal, which was also piled above it for 2 or 3 inches. When the charcoal was well alight, a layer of the charge was spread over its surface, then another layer of char-

coal, and so alternately until a conical heap was formed. A gentle blast was then started through a 1-in. blast-pipe, and when the charge began to settle the blast was increased. On the conclusion of the reaction, the slag and remaining fuel was removed and the metal allowed to solidify. An analysis of the metal showed 78% copper and 22% tin. A series of experiments were undertaken with varying proportions of the ore, and in every case copper-tin alloys were obtained. In the later bronze age, the varying qualities of alloys of different composition were well known, and the ancient metallurgists were obviously experts on the properties of alloys. The second point raised by Mr. Gowland referred to the supposed lost art of tempering bronze. In the old days the bronze castings for tools and weapons, were hammered at the cutting edges to produce the right degree of hardness and temper. No other method was ever employed, such as heat treatment. The same effect can be produced on modern bronzes, by hammering, and in fact an even greater hardness can be obtained. Thus the notion that the art of tempering bronze has been lost is a fallacy. Mr. Gowland might have added that soft copper tools can be hardened by heating them in contact with minerals containing arsenic or antimony, when a casehardening action is produced through the formation of a glass-hard copper-arsenic alloy. Analyses of old 'tempered' copper tools have shown them to contain nickel and other metals; thus the supposed 'tempered copper' is really a hard bronze.

## Electrolytic Determination of Copper

By C. E. TRAVILLION

In order to obtain a good deposit of copper by electrolysis, it is necessary to have the cathode well supplied with copper ions. If diffusion alone is depended upon to bring about this result, concentration changes will be set up in the electrolyte, with a result that a solution near the cathode becomes depleted of copper. Under these circumstances only a feeble current will insure a coherent deposit. In order, then, to utilize a fairly high current density and thus shorten the time of electrolysis, it is necessary to employ some sort of device to preserve the homogeneity of the solution.

The effectiveness of the rotating electrode can be duplicated and the manipulation simplified by an apparatus using air as a stirring agent. This apparatus consists essentially of a glass tube, through which a platinum anode wire is run, and a side tube for the introduction of air under small pressure. The anode wire is sealed in at the top, while the bottom of the tube is drawn out slightly with an opening for the release of the air bubbles. It also serves to lead out the anode wire. This terminates in a spiral, which is wound about the tube. The cathode is a platinum cylinder suspended about midway in the solution. The receptacle for the solution is an ordinary tall electrolytic beaker, which is covered with a split watch-crystal to prevent loss of solution by spattering. In operation the bottom of the tube is placed just above the lower edge of the cathode, and air is allowed to bubble through not too violently. An effective circulation is set up. The bubbles on rising create an upward current, which draws the solution under the cathode. This rises with the bubbles on the inside, which break on top, and a downward circulation along the sides of the beaker is produced. In addition to this, there is more or less agitation due to the action of the bubbles.—*The Chemist Analyst*.

THE Raub Australian Gold Mining Co., Pahang, Federated Malay States, produced gold worth \$176,000 during the year ended March 31, 1912, of which \$29,000 was written off at \$20,000 carried forward. At the Raub gold mines development is being done on 640 and 740-ft. levels.

## Operating Costs at the Goldfield Consolidated Mill

The following costs have been supplied by J. W. Hutchinson, metallurgist of the Goldfield Consolidated mill, which consists of 100 stamps crushing 100 tons per day, followed by classifiers, Chilean mills, tube-mills, concentrators, agitators, and vacuum-filters; while the concentrate is agitated raw with cyanide, roasted, given acid treatment, washed, mixed with mill pulp, and finally filtered. Precipitation throughout is by the Merrill zinc-dust method.

## The Wedge Mechanical Furnace

By L. S. AUSTIN

The Wedge calcining furnace, of the same general type as the McDougall and Herreshoff, has been before the public for some years, and its general appearance is familiar to metallurgists. It differs from the Herreshoff principally in having a large central shaft. The furnace is built in sizes from 12 to 22½ ft. diameter, and with three or more hearths and a dryer hearth. It may be arranged with a fire-box or not, according to the nature of the ore to be roasted. Fig. 1 is a seven and Fig. 2 a five-hearth furnace, the latter having a fire-box.

The ore is fed at the periphery of the furnace at the top or dryer-hearth, and is mechanically rabbled across it, entering the upper hearth at the centre of the furnace. By thus utilizing the top of the furnace for drying and pre-heating, the entering ore begins burning on the upper hearth almost at once, and need not wait until dried out. In fact, the heat used in drying out an ore containing 7% moisture may be computed as equivalent to raising the temperature of the dried-out ore to 250°C., at which a self-burning sulphide will begin to ignite.

The central shaft is 4 to 5 ft. diam., and is lined outside with fire-tile, so that it is not so hot inside but that workmen may enter at any time and remove the breech-block of any arm that is worn out. Workmen on the outside withdraw the arm through one of the doors and insert a new one, the men inside again replacing the breech-

block. Each arm, whether air or water-cooled, has its own supply and discharge-pipe, and hence independent regulation and replacement. The weight of the central shaft and attachments is not borne on a step, but on roller-bearings.

The furnace is built with flat firebrick hearths, since accretions are more easily removed from the flat hard sur-

FIG. 1.

FIG. 2.

face, which is better adapted for uniform rabbling. Fig. 2, the fire-box furnace, has an external fireplace, so that it can be used for a dead roast or for a chloridizing or sulphatizing roast. The passage, or drop-holes, from hearth to hearth are left of ample area, so that the velocity of the upward-passing gases is low, and hence less dust is carried away by the air currents.

THE Elmore vacuum plant at the mines of the Sulitjelma company, in Norway, produced 1126 tons of copper concentrate during the month of November.

## Discussion

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment. Insertion of any contribution is determined by its probable interest to the readers of this journal.

### No Intentional Misrepresentation

The Editor:

Sir—My attention has been called to a published statement by the Director of the U. S. Geological Survey, to the effect that I misrepresented myself while in private work as still being connected with the Survey. This does me an injustice. In fact I was for some time a member of the Survey and am proud, perhaps foolishly so, of the connection. Since leaving the Survey I have used a limited number of cards, usually in a social way, upon which I was designated as a member of the Survey. In every case where such cards were used, I explained verbally that I am now in private work. It was my usual practice to mark out the offending line. In no case were cards used with the purpose, or as I believe with the result, of deceiving the recipient. In the particular instance causing the trouble, an unmarked card fell into the hands of one who, knowing the facts in the case thoroughly, none the less used it to injure me in retaliation for criticism I had passed upon wild-cat drilling for which he was responsible. From this small basis of fact the large burden of criticism has grown.

I was careless and indiscreet but I was not dishonest. Nothing was further from my thought than to injure the Survey or to obtain information under false pretenses. Such a policy is neither expected nor tolerated by the company for which I am working.

LEON J. PEPPERBERG.

San Francisco, December 20.

[We are glad to give place to this explanation. The Geological Survey must protect itself from any misuse of its name and the Director was naturally jealous of its good reputation. It is pleasant to know that in this case conditions were better than they at first appeared.—EDITOR.]

### Flotation Patents

The Editor:

Sir—An advertisement has appeared in your pages for some months past which I consider does me a substantial injustice. It is an advertisement inserted by the Minerals Separation American Syndicate, Ltd., and purports to describe the situation as regards patents claimed to be owned by the Minerals Separation, Ltd. I assert that this company does not own the process which it is now using and charging royalty for, but that the process now in successful use by them belongs to me and is described in my patent 787814, dated May 22, 1903. The advertisement cites the House of Lords decision in an action between the Elmore and the Minerals Separation, Ltd. This decision has no bearing on anything but the use of oil and acid, and it involved processes none of which are now in use. The company claims in its advertisement to have 15 patents. It is obvious to anyone who will take the trouble to read through these that there is only one of them that in any way refers to the process now actually in use, and this patent was taken out over a year after my patent, which clearly and without any ambiguity described the flotation concentration processes now being used.

The essential principle underlying the process now being successfully used for the flotation of minerals is the beating in of air and the 'over-treatment' of the pulp by violent agitation, and my patent is the first to describe and show how this can be applied in practice.

It has been unfortunate for me that for some years I have been unable to protect my rights, but I am glad to say that this difficulty is now removed and I intend to hold both the Minerals Separation, and any other person

who may use my process, responsible for their infringement of my patents.

J. D. WOLF.

London, England, December 4.

### Market Support

The Editor:

Sir—As a regular reader of your interesting and instructive journal, containing sound editorials and many excellent contributions from your readers, I, who am manager of a mining company now systematically developing its property for production, have been much impressed as well as much mystified at times at some phases of the phenomena of the workings of the human mind regarding mining investments. There would appear to be considerable confusion regarding what constitutes a real mine investment and what a mere stock-juggling guess on the course of the market.

\*From long-continued observation of the phenomena, it would appear as though the losers are generally those who buy mine shares merely for a quick turn, for the purpose of selling out at a rise as soon as possible. People of this class are not mining investors at all. So far as the mining industry is concerned they might just as well—or, in fact, better—bet the money on a prize-fight, a horse-race, or a poker game, for they would not then forever after delude themselves and mislead others with the old time-worn fallacy that they had 'lost money in mining.' The *real winners* in mine investments are those who buy a stock 'for keeps' (usually while low in price) and who profit by the intrinsic enhancement backed by constant development of the mine represented, and finally by the enormous percentage of dividend returns.

Quite a large class of mining investors, as would appear, have been led to believe that unless 'market support' of some particular stock is assured from the outset, the enterprise or mine represented must necessarily be of little value. Whereas, it is proved by the history of nearly every big mine out in this big Western country of prolific mines that exactly the reverse condition has been the case. In other words, speaking frankly, a mining company conscientiously, intelligently, and consistently engaged in the actual work of developing its property cannot 'carry water on both shoulders,' as it were, by using its funds in supporting the stock market and expect to properly develop its mine at one and the same time. This is especially true during the period when the money for such development is coming in through the sale of treasury stock at subscription price. Later on, of course, when ore shipments have become an established factor, it is possible for a mining company to support the market very easily, but as a rule there is then no longer occasion for doing so, for capitalists are then only too glad to do this for them, and without being asked. By this time, however, the stock has risen so in value that the ordinary investor no longer stands to secure his rightful share of the profit that would be due him had he purchased earlier, at or near subscription price.

The point I wish to make here, however, is that a mining stock is not necessarily bad for the reason that at the outset there is temporarily no established market support for quick convertibility, nor is it necessarily good for the reason that there is financial support 'at the market,' especially as long as the market is advancing. In fact, some of the worst 'packages' ever handed out in the past were those which were artfully 'supported' during the going up time or 'unloading' period. Is it not a fact that the *true value* of the stock of any mining enterprise is not necessarily determined by the stock-market price of its shares at some particular time, but in the last analysis is definitely decided by the actual economic relation of mine development work to productive capacity and earning power, with the estimated time of such production properly and safely discounted in the early price to allow of liberal profit, such as is found only in the business of mining?

MARK E. DAVIS.

Oakland, California, December 20.

## The Bonanza Belt East of the Sierras

The Editor:

Sir—In the October 12, 1912, issue of the *Mining and Scientific Press* Mr. Storms has an article on 'Possibilities of the Mother Lode in Depth,' which interested me, not so much in the summary of what the different mines had done, as in the introduction which contains the arguments upon which he bases his conclusions. Of course he has brought out his now well known theory of the surface indications of ore-shoots and made this his main argument. In my limited experience and knowledge of the Mother Lode mines, I believe he is right. I also believe the broader principles of his reasoning apply to all mines. This pertains to the mines of the Mother Lode, which would come under one class and the same set of conditions would not necessarily apply elsewhere. However, in another district and another set of mines other general characteristics would apply and the successful mines would be found to exhibit certain similar conditions. I believe that in the whole so-called 'Bonanza Belt,' east of the Sierras, extending from Idaho into Mexico, an extent even larger than the Mother Lode, certain characteristic physical conditions accompany all the valuable mines and that a number of them can be classified. The similarity of these conditions is not only in surface indications and exposures, but in the general characteristics of the mines and districts as well. A careful study and comparison of some of the successful mines of this metallographic province will show a similarity of surface characteristics and without possessing these no prospect has made a mine or produced enough of the precious metals to be classified as successful.

In the past ten years the area under discussion has been studied in much detail by the United States Geological Survey and the contributions of W. Lindgren, F. L. Ransome, and J. E. Spurr contain many facts and suggestions relative to these points. Without going into a discussion of the various hypotheses of the genesis of the ore deposits and the ultimate source of the precious metals and ore-bearing solutions, it must be admitted that the conclusions of each of these geologists are so similar that it can scarcely be doubted that these various ore deposits were formed in the same general way, varying more or less in minor details, but in the whole producing orebodies possessing the same general characteristics throughout. In Professional Paper No. 42, U. S. G. S., 'Geology of the Tonopah Mining District, Nevada,' J. E. Spurr, in his comparison of this district with similar ore deposits elsewhere, goes into quite a lengthy discussion of this metallographic province and says: "Unquestionably the close relation between the Nevada mineral districts, Tonopah and the Comstock, with the far more numerous array in Mexico; and the individuality of this group as compared with other known veins of North America, shows a metallographic province." He concludes that at least in a large part this metallographic province coincides with the petrographic province of the Great Basin in which the general sequence of lavas is as follows:

1. Rhyolite. (Eocene).
2. Andesite (Miocene).
3. Rhyolite, with occasional basalt. (Miocene-Pliocene).
4. Andesite. (Late Pliocene—Early Pleistocene).
5. Basalts, and occasional rhyolites. (Pleistocene).

After a description of a number of mines in this province he gives the general characteristics of this group of veins as follows:

"They occur in Tertiary volcanic rocks of similar character in different localities, being chiefly Miocene andesites or rhyolites. They constitute strong masses or frequently branching and linked veins of quartz, which have as gangue essentially quartz, with frequently a little calcite, while adularia, barite, rhodochrosite, or rhodonite may also be present in limited amount. The ore is characteristically a silver-gold one, silver being usually predominant, though the relative proportions may be reversed and in some extreme cases either metal may occur with little admixture of the other. In any case the abundance of silver or gold, or both, in reference to the lead, zinc, iron, etc., is characteris-

tic. Silver sulphides, especially argentite, also stephanite and polybasite (with ruby silver) and gold, probably largely in the free state, are distinguishing features in the great majority of cases. Tellurides and selenides may also be present. Pyrite, blende, chalcocopyrite, and galena are usually present in varying quantity. Where they become predominant the vein becomes relatively low grade. Tetrahedrite, stibnite, and bismuthinite are also known to occur. The wall rocks are characteristically much altered to quartz, sericite, chlorite, calcite, epidote, pyrite, and sometimes adularia. Frequently the rocks nearest the veins are chiefly altered to quartz and sericite, those farther away to softer 'propylitic' alteration, consisting of calcite, chlorite, pyrite, epidote, etc. The rich ores occur in irregularly outlined portions of the lode called bonanzas. These bonanzas are of limited extent both horizontally and vertically. They are believed to have arisen as a consequence of the irregular intersection of transverse fractures or fissures with the main vein channel, producing maximum enrichment in these portions. Intervening portions may be low grade or barren. In the oxidized zone, silver chlorides and bromides, free gold, manganese oxide, etc., occur."

These general characteristics apply to the mines both as to surface and depth. I shall confine myself strictly to surface indications and formulate certain characteristic conditions that have existed in all of the successful mines of this province and must necessarily be found at the surface in any new prospect before any assurance of its successful development into a mine can be given. They are as follows:

1. The country rock should be Miocene andesite or dacite or a close connection with these formations should be shown.
2. The zone should show extensive fissuring (what is called a good break) with indications of strong cross-fracturing.
3. The zone should show extensive surface alterations, silicification near the vein, propylitic alteration farther away.
4. The zone should show some high-grade ore on the surface, not necessarily a continuous streak or in great quantity.

That the first condition is necessary, is evidenced by the fact that all of the successful mines in this province are either in this formation or connected with it. Spurr says in this connection: "In this metallographic province ores occur in Miocene andesites in the great majority of cases and their formation followed soon after the eruption of these rocks. In occasionally recurring cases (such as Silver City and De Lamar, Idaho, and others) they appear in Miocene-Pliocene rhyolites, which succeeded the andesites. . . . In general, however, the Miocene andesites of this province are, as Humboldt noted, the metalliferous formation par excellence."

In *Economic Geology*, Vol. IV, No. 5, W. Lindgren, in discussing metallogenetic epochs, places these ore deposits in class 5—deposits of the late Tertiary epoch with characteristics as follows: Ores, gold and silver. Lead and zinc not conspicuous, copper not abundant, tellurium and antimony are common. Continuing, with reference to these deposits in the late igneous rocks and the association of certain rare metals with certain magmas, he says: "Large areas of volcanic rocks are barren. The metal deposits seemed to have formed at or near the foci of igneous activity where connection could be established with underlying magmas. . . . Metallization is also dependent on the nature of the rocks in which the deposition takes place. . . . It is well established that magmas of different types contain different associations of the rare metals. . . . At the same time rocks of a given general composition may, in different localities, vary considerably in the quantity of rarer metals contained. Our knowledge of the contents of rarer metals in igneous rocks is fragmentary, but it is at least often the case that ore deposits formed after the eruption of an igneous rock will contain the rarer metals characteristic of it. It may be true that for each differentiated rock type there are corresponding types of deposits, varying with the conditions of deposition."

The similarity of the deposits under discussion is no

doubt due to the fact that they were formed at or nearly the same time by the same general volcanic activity, and the magmas from which they were derived were of the same general type and composition. Also to the fact that the andesites which were erupted at this time and in which the deposition has taken place are of the same nature. F. L. Ransome, in describing the geology of the Goldfield district, separates the Miocene flows into andesite, dacite, and latite, the two latter being of practically the same age and of the same general composition as the andesite. In all probability they are simply a differentiation of the same magma. Ore occurs in the three formations. It is quite reasonable to believe that the ore deposits of the Miocene rhyolites in the few scattering mines in this province are derived from the underlying andesitic magmas. However this may be, the great preponderance of the occurrences in the Miocene andesites establishes my first premise of the necessary surface conditions for a successful mine in the district, namely: The formation should be Miocene andesite or dacite.

Secondly, the zone should show extensive fissuring (what is called a good break) with indications of strong cross fracturing. This would seem to be a self-evident truth, but in considering the great number of veins in the andesites that are absolutely barren or of such slight content as to be worthless, it is apparent that something was lacking in their formation necessary to make commercial ore. In nearly every instance the successful mines in this belt are found at or near a deep-seated fault plane extending to depths not yet reached and accompanied by branching faults and extensive cross fracturing. The whole constitutes a great fractured zone, through which the mineralized waters and vapors have circulated, depositing minerals and replacing country rock. It looks reasonable to suppose that this deep-seated fault has opened the way to the source of the metals below. The Comstock lode is a vein four miles long, which has formed in Tertiary eruptive rocks, chiefly andesites, along a fault line, having a maximum displacement of three thousand feet. Tonopah, while not showing any one fault as extensive as this, has hundreds of smaller ones extending to depth.

In Goldfield, the main Columbia Mountain fault traverses the district its entire length and although the ores, so far discovered, are not found in the fault, they are found in the crushed and faulted country directly east of it, the hanging wall side of the fault. The faults found here are secondary and may connect with the main fault in depth. Writers describe the veins of Pachuca and Rey del Monte as analogous to Tonopah and the Comstock, in that they occupy deep fault fissures. At National, Nevada, the main fault fissure extends for several miles across the country and the bonanza gold and silver ore is found directly in it. The Nevada Hills mine at Fairview shows a great number of faults and a number of them are deep seated. As a rule it is the hanging-wall side of the fault that has moved and in moving has been crushed and fractured, thus forming a zone of easy access for the mineral-bearing solutions. The large number of successful mines in Mexico in the andesite formation are all similar in this respect, so it must be concluded that it is a necessary condition and without this extensive fault breaking a prospect in this province will not 'make good.'

The third condition, that the zone should show extensive surface alteration, silicification near the vein, and propylitic alteration farther away, is directly dependent on the second condition. Without extensive breaking and faulting the mineralizing solutions, vapors, and gases could not circulate freely and there would be put little metasomatic action. On the other hand this condition might exist without metallization. The solution might be barren of metals and the silicification and propylitic action still take place over a large broken area with the result of not producing a mine or even a surface prospect. Nevertheless it is a condition that is attendant on all the successful mines of this province and therefore a necessary surface indication linked with the preceding condition, number two and the following one, number four. Becker, Spurr, Lindgren, and Ransome have

discussed this condition in many of its phases in some detail in a number of their reports.

Condition four is that the zone should show some high-grade ore on the surface, not necessarily a continuous streak or in great quantity. The showing of this ore indicates that the circulating solutions, vapors, or gases carried the precious metals in such quantities as to form in favorable places commercial ore. With the three preceding conditions present it then becomes almost a certainty that ore-shoots of good size will be found. I think I can safely say that there is not a valuable mineral zone in this whole province that does not show at some place, somewhere in it, high-grade ore cropping on the surface which was either the top of an ore-shoot or an indication of an ore-shoot. One of the most important characteristics of these mines is their bonanza or high-grade ore-shoots, and it is from these bonanzas that their great production is made and not from large bodies of low-grade ore. Without the bonanzas they would be very ordinary mines, and it is this characteristic which places them in the successful list. Without possessing this high-grade ore on the surface in the favorable places (such as the intersection of the main fissure with a cross fracture) I would not hope or expect to open much of a mine in depth. In using the word mine, I do not wish to be understood as confined to claim lines on the surface, as often an ore-shoot rakes from one claim into another at depth though the latter has no surface showing and belongs to another corporation. In reality the whole vein and ore-shoot forms one mine.

It is not to be understood that the four conditions outlined are all in which a similarity exists among the successful mines, but when found on the surface in an undeveloped prospect the chances for opening a successful mine are exceedingly favorable. The work of examining and determining these features on the surface in this metallographic province is greatly relieved by the absence, in many instances, of trees, underbrush, and deep accumulations of soil—different in this respect from many parts of the Mother Lode country. With the first three conditions found, the presence of which is quite easily determined, intelligent prospecting should disclose in a short time whether or not the fourth condition exists. If it does the money and time spent in development will not be wasted.

H. C. CUTLER.

Reno, Nevada, December 10.

## Bureau of Mines Expenditure

Estimate of expenditure for the Bureau of Mines for the fiscal year June 30, 1913, to June 30, 1914, is as follows:

For general expenses .....	\$70,240
For investigating mine accidents.....	347,900
For fuel investigation .....	135,000
For investigation into the treatment of ores, and other mineral substances .....	250,000
For inspecting mines in Alaska .....	6,500
For books and publications .....	2,500
Toward the erection of a suitable laboratory for Bureau of Mines at Pittsburg.....	115,000
For the collection of statistics concerning accidents in the mining industry, etc.....	25,000
For the purchase or lease of land for headquarters for mine safety cars .....	2,000

Total estimated expenditure.....\$954,140

The increases asked for include \$4140 for general expenses, \$27,900 for investigating mine accidents, \$200,000 for investigation into the treatment of ores and other mineral substances, \$1000 for the purchase of books and other publications, \$115,000 toward a new fire-proof laboratory, and \$25,000 for the collection of statistics concerning accidents in the mining industry and other interests.

IRON ore shipments from Lake ports for the year are estimated at over 47,000,000 tons. The principal shipping ports are Superior and Duluth, each of which furnishes about one-quarter of the total shipments.

### FAIRBANKS, ALASKA

WORK OF THE MILLS.—HIGH GRADE ORE.—RAILROAD  
EXTENSION.

Only good reports come from the plant of the Chatham Mining Co., where the 4-stamp mill is in constant operation. According to late reports, it is an easy matter to supply the mill with ore. While the vein will probably average 2 ft. or less of good ore along the length of the adit, in one place on the shoot a width of 3 ft. of excellent grade is maintained for 30 ft. The owners are well satisfied with their purchase. The lack of snow and consequent impossibility of hauling wood has caused the operation of the Willis & Larson 5-stamp Hendy mill to be very intermittent. The mill has only been in operation a few weeks and no clean-up will be made till a wood supply guarantees a reasonable tonnage. Plenty of good ore awaits the mill both from the lease held by the owners of the mill, Willis, Larson, Greske, and Rodset, and from other leases in the neighborhood. Lee Green and Lysle Brown will have 100 tons to run through by the first of the year. They hold a lease on part of the Jupiter-Mars group.

The 2-stamp Hendy mill erected at the Rexall claims by Horton & Cooper has just been completed and will be crushing steadily the remainder of the winter. Plenty of ore is blocked out to now assure an adequate supply for many months. The last two lots of 10 tons each averaged \$170 and \$65 per ton respectively. Since the milling of these two shipments at the Fairbanks test mill, no ore has been crushed. The Rexall property should be a good producer. The Little Giant mill erected by Furstenau & McCarty is still idle, as the drifts on the 140-ft. level have not as yet cut the ore-shoot found above. While waiting for the Pennsylvania to produce ore, the mill will handle any customs ore brought in. The operation of the mill, judging from the ore already crushed, seems to be very successful and has proved a good gold saver for the local class of ores.

After finishing assessment work and the cutting of necessary timbers, Cook Bros. on Fairbanks creek, have started driving an adit on the vein found by them several weeks ago. Where opened, the ore was high-grade and it is expected that several thousand dollars will be produced this winter by shipping to customs mills. The last reports from the Crites and Fallman property are very encouraging, the same high-grade ore being found in the adit as showed in the prospect holes above. Competent judges say that for the development work done, the showing made is as good or better than that made by the Rhoads-Hall property at that stage of development. It is very probable that a mill will be put on next summer, as 100 ft. more driven on the adit in the same kind of ore will assure a fortune for each of the owners.

It has come to light that the figure \$100,000 given as the option price on the claim owned by H. H. Hoover was grossly exaggerated, \$30,000 being nearly the correct figures. The people holding the option are busily engaged in tracing the Crites and Fallman vein across this property and will probably take up the option later. Thirty-seven ounces of quartz gold was brought to town recently by Charles Watson, who claims to have found a pocket on lower Fairbanks creek. The gold had been pounded out without amalgamation. The position of the find is still secret.

Good news to the quartz miners is the fact that the Tanana Mines railroad will extend its line next year from Chatanika up Cleary creek. The shortage of wood will be relieved, freight rates lowered, and communication with town made shorter by this extension. The increase in volume of freight going to the quartz properties exclusively has decided the manager to make this extension. While the properties being worked are going ahead fast, it is astonishing to note the number of good prospects lying idle; prospects as encouraging on the surface as the ones being developed. That such a condition will not last very long, however, is a conservative guess. The regular heavy clean-

ups from certain properties have started a quiet movement to tie up good properties and chances are that next spring and summer the movement will become a scramble.

Since moving the 5-stamp mill to its permanent position on 11 Above Cleary creek, the Newsboy company has had two clean-ups of \$4600 each. While the first was produced from 225 tons of ore, the record resulted from a 100-ton run. The foreman reports plenty of ore on hand to run half time till the 3rd level is opened and more stopes opened on the 2nd level. While development work is going on at the mine, customs work will be done at the mill.

### JOHANNESBURG, TRANSVAAL

IMPROVED MINING CONDITIONS.—VENTILATION OF RAND  
MINES

Since the passing of the recent legislation of various kinds with the object of preventing miners' phthisis in the Witwatersrand mines, there has been, as a result, a striking improvement in the underground conditions largely due, no doubt, to the onerous cost the compensation clauses of the Insurance act were likely to inflict upon the mines if the old conditions were allowed to continue. There can be no doubt that the greatest benefit has been derived from the more general use of water underground with the object of preventing the circulation of dust. In fact, instead of some of the miners complaining about the scarcity of water supplied to them for this purpose, their complaints are now mainly that not only have they now too much water forced upon them, but they are compelled by the mine officials to use water so as to comply with legislation. Generally speaking, the underground conditions have considerably improved, confirming the statement I have frequently made that unless compulsion were used at all the mines on the Rand to the same extent to get the miners to use water, there was little hope of improvement, owing to the cure being regarded as so simple that those concerned were not inclined to adopt it. It is not at all unlikely that owing to the more general use of water underground and the improved conditions brought about, that miners' phthisis may become as rare as it has recently been prevalent on the Rand.

Attention has also been called to the inadequate manner in which the deep-level mines of the Rand are ventilated. The other day the manager of the Cinderella Deep said that the highest temperature underground there was in the neighborhood of 82°F., and that it was no small task to induce the natives to work in such high temperatures. Now, 82°F. is not at all a high temperature for a South African negro to work in, and as it is well known that at this particular mine the negroes do complain about the hot workings, the temperature in some places must be nearer 90 than 80°F. Now that mining operations have attained a considerable depth on the Rand, it behooves those in charge of the mines to see that they are properly ventilated, for it is evident that at a depth of 5000 ft. from the surface something more than natural ventilation will be required. It is quite true that every mining group of importance has adopted fan ventilation for the deep mines during the past two years, but the mere fact that 200,000 cu. ft. of air may be passing through the fan chambers does not prove that the mine is well ventilated. The hanging and foot-walls on the Rand are so stable and sound, as a rule, that permanent cavities allow much of the air to escape by a short cut without passing through the stopes, many of which are quite as hot as before artificial ventilation was introduced. To ventilate a gold mine on the Rand is no easy matter; the warmed-up current of air becomes more attenuated every yard through its short circuiting to the upcast shaft, and there are so many ways in which it escapes that by the time the stopes are reached the current has practically disappeared. It must not be overlooked that fan ventilation has the effect of drying the underground atmosphere by the extraction of thousands of gallons of water in the shape of moisture, and it is here that the advantage of well spraying the underground workings will make itself felt. While there is

much room for improvement in the distribution methods on the Rand, the more general use of water for the destruction of dust has brought a welcome change for the better in underground conditions. So far as can be seen at present, there is no reason to prevent the mines on the Rand becoming the most healthy as well as the most profitable from a miner's standpoint of any in the world.

## NEW YORK

### FACTORS IN THE COPPER MARKET.—THE DOE RUN DISPUTE.

#### —NOTES OF COPPER MINES.

The old-fashioned idea of the real test of strength among young men gathered together either at work or at play was designated 'pulling square hold.' Two contestants, grasping a pitch-fork handle, seated themselves facing each other upon the ground with the soles of their feet planted squarely against one another; the victor was supposed to pull his antagonist into a standing position. Something akin to this primitive tug-of-war now exists between the copper producer and the copper consumer. The rounding up of the copper situation has been frequently discussed in this column, as a typical working out of concentrated control of an industry such as has come to prevail in so many and varied lines. It is only a natural consequence therefore that the consumers and the crowd which is in control of the copper metal market should be 'pulling square hold' with the price of copper metal between them instead of the pitch-fork handle. The metal market is almost stagnant, with the sellers of copper refusing to budge from the price of 17 $\frac{3}{4}$ c. and the consumers refusing to come into the market at this price. Discussion has again become rife as to the various phases of the copper supply and a good deal is being said about the withholding of blister copper from the refinery vats, and alleged discrepancies between refinery output and known production at the mines. For some reason the copper metal market seems always to have been a temptation to large pools with great financial strength, though the final chapter in nearly every attempt to corner copper has been one of disaster. Recent testimony before one of the congressional investigating committees was given by John D. Ryan regarding the copper manipulation of 1907 when the metal reached its record price, the slump being followed by a long and rather disastrous period for the copper producers. In the recovery from that period the present concentrated control was perfected, and the market stabilized. It is an important development that the Federal authorities are about to begin an investigation of the copper metal market, looking especially to the concerted action between the principal sellers of copper, the Phelps-Dodge Co., the United Metals Selling Co., and the American Smelting & Refining Co. It is significant that Amalgamated Copper should have had aggressive support on the day the announcement first appeared. There exists no stronger financial aggregation than that which is now in control of copper, indeed it may almost be said that it includes almost every one of the financial groups of the heaviest weight. The gross financial resources of this body of men and institutions are as nearly limitless as is possible. If the law department of the Federal Government in its endeavor to bring to book the violators of the so-called Sherman anti-trust law is looking for a test case wherein to assail the forces opposed to it, where their greatest strength is massed, a better point of attack could not be chosen.

The fight which is being waged against the officers of the Doe Run Lead Co. has been brought to New York, and the complaining stockholder, Robert Holmes of St. Louis, has petitioned the Attorney General of the state of New York to bring an action for the removal of the officers and directors. The complainant alleges that he owns, together with various members of his family, some 56,600 shares of stock, and complains of various specific acts of mismanagement in the conduct of the Doe Run Lead Company in connection with the St. Joseph Lead Co. and the Mississippi River & Bonne Terre Railway Co. in the handling of notes and bonds, the purchases of supplies,

and payment of salaries. The officers of the Doe Run Lead Co. and the St. Joseph Lead Co. are practically the same.

Congress has been petitioned for an enlarged appropriation for the Bureau of Mines. The data gathered by the Bureau show some surprising conditions. The layman had rather been inclined to take it for granted that mine conditions, outside of coal mines, were not greatly in need of investigation or readjustment. From the data so far accumulated the death roll in lead, zinc, copper, and other mines seems to be unduly high, both as to those caused by accident, and those resulting from tuberculosis. It is something of a matter of surprise to learn that coal miners do not suffer as much from the last named cause as the workers in other mines. A share of the energies of the Bureau of Mines is also to be devoted to a search for metallurgical methods that will permit of the winning of a profit from ores of the various low-grade mining districts of the West. Every move in this direction is to be applauded and seconded with enthusiasm and it is no disparagement to the Bureau of Mines to say that in taking up this work its director J. A. Holmes tackled a very large problem and one which has engaged the attention and taken the capital of many individuals and organizations.

The Shattuck-Arizona Copper Co. has declared a dividend of 50c. per share. The last dividend paid was in January 1911. At present the Shattuck is shipping but 250 tons of ore per day, but this shipment is to be doubled within a short time. The trades which have been under way for the Shattuck property are evidently being held up while the value of the mine is demonstrated; undoubtedly the result will be to force the would-be buyers to pay high for the property if it is to be taken over. The company has recently come back as a dividend payer and a shipper of metal, and is to sell its product through Adolph Lewisohn & Sons. Lewisohn & Sons also handle the output of the Miami for the General Development Co., and from these two sources will have the marketing of about 4,000,000 lb. of copper per month. The Inspiration Consolidated Copper Co. has placed an order with the American Bridge Co. for some 8000 tons of steel to be used in the new plant, foundations for which are just going in.

The Alaska Gold Mines company, which has been several times compared with the so-called 'porphyries,' or low-grade milling copper properties, bids fair to carry out the comparison in a striking way. As was the case with Chino and with Braden, the orebodies are proving to be much larger than first estimated. It is said that the present development justifies the multiplication by four of the first tonnage estimate of 50,000,000. The construction of the 6000-ton mill is just about to begin, and the management is already anticipating the necessity of adding 14,000 tons daily capacity within two years, and is talking of a profit of \$7,000,000 annually.

Walter L. Fisher, Secretary of the Interior, makes some interesting suggestions in his annual report in regard to the present mining law. On this point Mr. Fisher writes as follows: "It is becoming increasingly evident that the lode mining law needs changing in one respect, at least. The law at present does not provide for the creation of any rights in supposedly mineral land, except by the issuance of patents, and in that regard Congress has provided that a patent can follow only on a legal location and has said 'but no location of a mining claim shall be made until the discovery of the vein or lode within the limits of the claim located.' This law seems to be ill calculated for a district where, as is the case notably in some of the copper mining districts, the ore lies at depths of hundreds and sometimes thousands of feet. The expense of actual discovery of the vein or lode within the limits of any particular claim in such cases involves deep exploration, either by drilling or by the sinking of a shaft from the surface, or the extension of a tunnel into the claim. Either of these operations may involve great expense, and it has been repeatedly urged on the department that investors are reluctant to spend the money required without further assurance than the law as it reads at present can give them. "It seems possible by a change in the law to keep in force the policy of the gov-

ernment expressed in the mining law of rewarding the actual discoverer of valuable veins, while at the same time giving such protection during the work preliminary to actual discovery as would make it possible for capital to invest, taking no more risk than that inherent in the question whether there is or is not in fact valuable mineral in the place where it is sought." Mr. Fisher's suggestion is full of meat, but he fails to touch upon one of the most pernicious factors in deep-level mining districts; the doctrine of apex rights as now established by the courts.

At the annual meeting of the stockholders of the New York and Honduras Rosario Mining Co. this week, Ambrose G. Todd, J. Ralph Jacoby, and Sidney Abenheim were elected to the board of directors to succeed L. F. Valentine, William Kengel, and Ernest Shernikow. The board of directors immediately organized by electing Lewis L. Clark first vice-president to succeed L. F. Valentine, and Sidney Abenheim was elected the second vice-president. The other officers and directors were reelected.

### SPOKANE, WASHINGTON

NORTH WASHINGTON MILL.—PROGRESS IN CHEWELAH DISTRICT.

A group of claims bordering on the Spokane Falls & Northern railway, about 20 miles north of Republic, and owned by the Phoenix Gold & Copper Mining & Milling Co., is being operated by an adit, now in 230 ft. The plan is to drive it a total of 1800 ft. The portal is distant 700 ft. from the railway track, at an elevation of 140 ft. The object is to intersect six contact veins bearing gold, silver, copper, and lead, which vary in width from 6 to about 100 ft. The veins are contacts between porphyry and limestone, and of fair size. The result of the last clean-up at the North Washington Power & Reduction Co.'s mill, on November 30, was a bar of base bullion weighing 266 lb., valued at \$10,740. The Ben Hur Leasing Co. is shipping 10 carloads of ore per week to the Granby smelter at Grand Forks, British Columbia. The ore is reported to be increasing in value. The Republic Mines Corporation has closed down the Surprise mine, where operations will be suspended until the termination of the suit for damages against it by the Quilp Gold Mining Co. In the meanwhile ore is being drawn from the Lone Pine mine to keep the North Washington Power & Reduction Co.'s mill running.

In the Metaline district the Lead & Zinc Mining Co. has put on 50 men, and is surveying for and building a wagon-road on a convenient grade, to be used later on for an electric railway. The company is preparing to erect a mill for which the machinery has been ordered. A power line will be built from the power-plant of the Inland Portland Cement Co. to the lead and zinc mines for the purpose of operating a compressor and power drills at the mine by electric power.

In the Chewelah district operations will be resumed next March on the Imperial mine, when a pump will be installed and the shaft will be continued down to the 300-ft. level. A pump is being installed at the Blue Star mine, now under lease to Mark Mitchell, the president of the Blue Star Mining Co. The United Copper Co. has finished a 200-ft. adit on the Widow's Mite claim, one of the United Copper group. The Widow's Mite claim adjoins the Blue Star, from which the highest grade silver ore in the district has been taken. Development work is being done on the claims of the United States Copper-Gold Mining Co. by F. A. Eickmeyer, a stockholder. The bulk of the work is the extension of an adit on the east line of the company's group of claims which is expected to tap the main vein inside of 30 ft. The Orient Gold Mining & Milling Co., Ltd., is sinking a shaft, now down 140 ft. The 100-ft. level has been opened by a drift 55 ft. and a cross-cut 85 ft., all in quartz which assays from \$15 to \$20 per ton in gold and silver and a little copper. Small streaks of exceedingly rich ore have assayed as high as \$33,000. The company is talking of installing a concentrating plant.

### RHODESIA

SHORTAGE OF WATER-SUPPLY.—REORGANIZATION OF THE MINES DEPARTMENT

The chief topic of conversation both in mining and agricultural circles is the drought. The position daily is becoming more serious. Farmers all over Matabeleland and Mashonaland have suffered severely, and several mines have had to suspend milling operations in consequence of acute shortage of water. Unless heavy rains fall at an early date, many more properties, among them some of the leading producers of the country, will be in a parlous plight, and wholesale restriction of output will be inevitable. In Southern Rhodesia the rainy season commences usually about mid-October and continues to the end of March or early in April. During last season, however, little rain fell, and it looks as if 1912-13 will be an even more dry season than the preceding one. As an instance of the severity of the position, the Sebakwe river, from which the Globe & Phoenix obtains most of its water and which normally does not run dry until October, dried up this year in April. The management of the mine dealt promptly and energetically with the problem of securing stored water and obtained sources of temporary supply at considerable expense. It was hoped this year's rains would be early, but this was not the case and the situation is causing much anxiety.

On the Witwatersrand the mines secure large supplies through the Rand Water Board, of which all the Main Reef

MILL AT THE WANDERER MINE.

properties are members. In this country, however, there is no co-operative supply organization. Mines are dependent on adjacent rivers and streams, and in a less degree on the comparatively small quantities of mine-water pumped. The prevailing drought accordingly has put the majority of mining concerns in a very serious position, and unless there is a speedy change in climatic conditions wholesale closing down will result.

It is generally understood that the mining department of the British South Africa Co. is to be reorganized, but on what lines it will be effected is not known. A. H. Ackermann, resident mining engineer for the British South Africa or Chartered company, is in England, and it is believed the main object of his visit is to confer with the directors as to the future constitution and personnel of the Rhodesian Department of Mines. There has of late been considerable friction between the official Mines Department and the unofficial mining industry. In the first place, objection was raised to the formation of the Rhodesian Mines Development Co., and not without reason. This venture was formed by the Chartered company early this year for the purpose of prospecting and developing claims with the object of bringing properties to the flotation stage and the forming of subsidiary companies. The unofficial Chamber of Mines objected to the launching out of the Chartered company into the field of private enterprise on the ground that the Rhodesian Mines Development Co., being a subsidiary project of the government of the country, would enter the competitive arena on unduly advantageous terms. It was protested that the flotation of such an undertaking should remain in abeyance until the administrative and commercial departments were more clearly divorced than at present.

In another regard there has been considerable antagonism

between the mining industry and the Mines Department. Mr. Ackermann has lately reported on and superintended work at a number of mines in the capacity of consulting engineer. Professional and private consultants and metallurgists in Rhodesia have been up in arms against what they allege to be unfair competition from Mr. Ackermann's office. Henry Birchenough, one of the Chartered company's directors, was in Salisbury some little while ago and was waited on by a deputation of gentlemen representing the mining engineers and assayers doing business in the country. They protested against the resident Government mining engineer holding appointments as consulting engineer to private concerns, and to his staff making examinations of properties other than those of *bona fide* small workers (who are entitled to Government advice and assistance), and doing them, moreover, at prices that defied competition. The deputation was sympathetically received by Mr. Birchenough and it is probable that the whole matter will thoroughly be gone into during Mr. Ackermann's visit to London.

The syndicate of Johannesburg capitalists engaged in developing a cassiterite deposit in the neighborhood of Chishawasha valley, to the east of Salisbury, maintain a policy of secrecy. No official statements have been given, but it is understood that development continues to give highly encouraging results. It is believed that two or three of the leading Rand houses are interested in the discovery. Exploitation is to be hastened. A compressor plant should be working at an early date, and as the lode is stated to be exceptionally large, a good tonnage should quickly be blocked out and valued.

The Jumbo mine, in the Mazoe district of Mashonaland, has, unfortunately, to be added to the list of Rhodesian mines that have been tried and found wanting. At one time the company was earning substantial profits, but for months past it has been evident that the mine was on its last legs. The ore-shoot now appears to be exhausted and the consulting engineer holds out to shareholders no hope of any discovery which might redeem or save the situation. During the year the debentures have been substantially reduced, but there still is about £10,000 outstanding. The past year's work shows a loss of £27,490 as compared with £12,850 for the previous year. On June 30 the cash on hand, etc., amounted to £17,800, and at the best it would seem that the company will be able to do little more than pay off the remainder of the debentures. The property has been thoroughly tested and well managed, but the ore did not come up to expectations.

### LONDON

#### INDIA'S GOLD ABSORPTION.—WORK AT GOSS MOOR.—SIBERIAN MINERAL RESOURCES.

There is still no little discussion concerning India's absorption of gold. It does seem somewhat startling when it is considered that to no small degree the world's primary market for the yellow metal is at the mercy of one of the dependencies of the British Empire. The amount of gold absorbed by the Hindoos within the past fiscal year is estimated at 25% of the world's output. This taking of gold, large though it is, would not be specially important if the metal so absorbed remained liquid and moved back and forth as the exigencies of trade might demand, but of the gold which goes to India the percentage which remains in circulation is negligible. The overwhelming bulk of the metal is hoarded and lost to circulation. This Indian situation becomes particularly important at this time because it is recognized on all sides that both at home and abroad the necessity for liquidation is impending, and no inconsiderable amount of financing must be done in the industrial world within a short time, while abroad there is a huge war debt to be taken care of as soon as peace is finally restored. In the light of these factors the figures showing the imports of gold by India during the past five years, the decrease in silver importation, and the more than proportionate increase in gold imports are exceedingly interesting. The following table gives the imports of the two precious metals for the past five fiscal years, ended March 31, imports being for

private account and the figures showing the equivalents in United States currency:

	Gold.	Silver.	Total.
1908 .....	\$56,270,250	\$32,512,497	\$88,782,747
1909 .....	15,295,847	38,786,764	54,082,611
1910 .....	70,279,103	30,369,395	100,648,498
1911 .....	77,760,063	27,918,806	105,678,869
1912 .....	122,490,684	17,167,435	139,658,119
Total, 5 yr. . .	\$342,095,947	\$146,754,897	\$488,850,844

While the trade balance and metal imports are specifically a matter of concern as between London and Calcutta, how far the the drift of the yellow metal eastward is to affect the world's supply is of vital importance to America. The whole complicated structure of modern credit is, at least theoretically, based upon gold reserves, and in the maintenance of international credit gold is considered one of the prime factors in maintaining a just equilibrium.

During the past two years I have referred several times to the tin-gravel venture at Goss Moor, Cornwall, promoted by C. G. Lush, an Australian expert in gravel mining. Unfortunately, this venture is not so successful as expected. An account of the method of working was given in *The Mining Magazine* for July last, where it was shown that the alluvium is broken down by hydraulicking, and raised by a pump to a floating barge containing the sluice-boxes, this being a usual Australian practice. A new steam-plant, substituted for a suction-gas plant, commenced operations on August 15 last year, and during the 12½ months from that date to August 31 last treated 193,620 cu. yd. of gravel. The yield was 60½ tons of tin concentrate assaying 73% metal, and selling for £7561. The cost of operations and administration was £9642, so that the loss was £2081. The results are disappointing, and various suggestions as to the future have been made. One is to form a subsidiary company to treat part of the property on the northern side by a bucket-dredge. It is intended also to change the power again, this time to electricity, to be supplied by the local power company; it will thus be possible to use 5 or 6 small installations of barges, pumps, and monitors instead of a single large one as at present. The present cost per yard works out at 12d., which is double Mr. Lush's estimate, and compares with 5d., the figure quoted by him in connection with a property in Australia.

A very interesting report prepared by the Belgian minister to Russia covering the mineral resources of Siberia has just been given out. The northern part of Asia is one part of the globe which has not been explored in every quarter by the prospector, and the practically virgin character of this vast expanse of country has more than once drawn the attention of pioneers in many lines of industry. Extracts from the minister's report are as follows: Graphite exists in very large quantities in a mountainous region in the vicinity of Blagovestchensk, and these deposits are at present for sale. Gold-prospecting permits have been issued to the number of 664, and 30,000 workmen are employed in the gold-mining industry. There is little doubt that when the Amur railway is completed the output in the Amur province will be doubled. In most cases, however, the machinery is so far primitive in character. There are many deposits of silver, but the price of the metal does not encourage work upon them. Over 3000 tons of copper was extracted in 1911, the whole coming from western Siberia. Since the opening of the Trans-Siberian railroad, coal-mining has developed by leaps and bounds, and in one of the areas 20 of the collieries are state owned. Iron ore exists in many areas, and it is predicted that the Maritime province will soon become the centre of an important iron industry. Only lack of capital has prevented smelting works from being erected. The full development of the country depends primarily upon railway transportation, and until that has been improved progress must be slow, but at the same time great prizes may be secured by the adventurous in the course of development of an area so vast and known to be so rich in mineral wealth.

## General Mining News

### ALASKA

#### CORDOVA

On December 8 a disastrous snowslide occurred on Copper mountain, about 15 miles from Strelna, on the property of the Great Northern Development Co. The slide came with such force that the men who were in the buildings of the company were unable to escape. Four bodies were recovered, and five others were still buried at the latest advice. About a year ago a similar occurrence happened, but no lives were lost. The mines have been worked for eight years, and are well developed, and contain a large tonnage of fair-grade copper ore.

At the Dougherty property, on Shoup glacier, a drift has been driven 25 ft., and 205 sacks of ore saved. There are five distinct veins on the claims.

#### FAIRBANKS

O. P. Gaustad, from lower Cleary creek, has staked a water-right on the upper Chatanika river, and will erect a hydro-electric plant near the mouth of Pilot creek, a tributary of the Chatanika, above Cleary creek, and transmit power to the stamp-mills and mines in the Cleary and Fairbanks creeks districts. A ditch 11 miles long will be dug, and 5000 miner's inches of water required. A steam-plant will be operated in winter, when water is not procurable. Wood will be floated down the ditch in summer and stacked for winter use. It is estimated that there is over 100,000 cords of wood available near the proposed ditch.

#### IDITAROD

The Guggenheims have acquired the Mohawk and Glen claims on Flat creek, and a small property on Otter creek, the price being \$106,000. It is intended to erect two more dredges in Flat creek next season. A water right has been staked on Otter creek, and a ditch four miles long will be dug to carry water for a hydro-electric plant.

#### JUNEAU

During November the 240 and 300-stamp mills of the Alaska Treadwell company worked 27.71 and 29.05 days, respectively, crushing 29,708 and 45,108 tons of ore. From amalgamation \$100,003 was saved, and from cyaniding 1539 tons of concentrate \$95,504 was recovered, the total realizable value being \$193,552. Operating expenses were \$75,011, and construction \$3983, leaving a net profit of \$114,557. Development covered 651 ft., and the stock of broken ore decreased 10,593 tons.

#### VALDEZ

The Amalgamated Development Co., at Katalla, has six oil wells in operation, the newest producing 40 bbl. of high-grade oil per day. Next spring the company will continue boring operations. The Pacific Coal & Oil Co. also has large holdings near Yakataga, and along the coast between that place and Bering river, on which several thousand dollars are expended yearly in assessment work, which, it is said, is very closely inspected by Government agents.

### ARIZONA

#### COCHISE COUNTY

At the Turkey Creek mine, in the Paradise district, J. Q. Johnson and associates have opened 20 ft. of galena, and shipments will be made at once to El Paso.

#### GILA COUNTY

The Sleeping Beauty Copper Co., owning 20 claims, 10 miles northwest of Globe, are being worked by lessees, who are sinking an incline shaft 150 ft. Prospecting has opened promising gold, silver, and copper veins. A number of men are working at the new shaft of the Douglas Copper Co., which will be sunk 300 feet.

Excavation for the Inspiration mill has been under way for three weeks, and good progress is being made. Development at the Inspiration Consolidated during November was: Inspiration section, 3650 ft., and Live Oak section,

500 ft. Between the Scorpion and Joe Bush shafts 618 ft. remains to be driven, and 1300 ft. between the Scorpion and Colorado shafts. At the Joe Bush shaft 12,000 tons of ore is on the dump. The 80-ton waste pocket at Live Oak No. 2 is about finished.

#### MARICOPA COUNTY

A 90-day option has been taken on the old dump of tailing of the Vulture mill, above Wickenburg, by W. H. Seamon, of the Swansea smelter. A few carloads will be used for experimental purposes. It is thought that the tailing will be used mostly for converter linings. There is about 80,000 tons in the dump.

Placer mining on an extensive scale will soon be under way in the San Domingo district, across the Hassayampa river from Wickenburg. About 500 acres, owned by Phoenix and Wickenburg people, will be worked by sluicing, and water will be secured from a pipe-line being laid to the Monarch mine, eight miles distant, the pipe passing over the placer ground. Years ago this field was extensively worked, but want of money for water-supply caused the placer to be deserted, after the coarser gold had been removed. Platinum has been found all over the district. The mill of the Monarch mine has now a full supply of water.

#### PINAL COUNTY

It is reported that the Guggenheims have bought the Black Diamond group of claims, in the Superior district, adjoining the Silver King mine.

### CALIFORNIA

#### AMADOR COUNTY

(Special Correspondence.)—The cross-cut from the 500-ft. level of the South Jackson is expected to cut the vein within a short time. Good progress is being made. San Francisco people are interested. Jeffrey Schweitzer is manager. A heavy flow of water has been tapped by the drift from the Lincoln Consolidated shaft to the Wildman workings. Work at this point has been suspended until arrangements have been made to guard against accident. It is thought the drift has broken into the Wildman shaft workings. It is understood the parties holding a bond and option on the Doyle claims have been granted further time to make final payment. The suit to quiet title to the property was recently heard before Judge McSorley, and decree granted. Development at the Argonaut is reported to be satisfactory. This is the second deepest property on the Mother Lode, its 2800-ft. incline shaft being surpassed only by the vertical workings of the Kennedy. The Bunker Hill Consolidated Co. paid its regular monthly dividend of 5c. per share on November 15. This makes a total of \$120,000 paid in 1912 and a total to date of \$550,000. Good ore is being opened in the 1950-ft. workings. About 30 men are employed at the Plymouth Consolidated group, and it is reported that vigorous development with an increased force will soon commence. British capitalists are interested. The mine is situated near Plymouth. Rich ore continues to come from the Mountain King, in the Pine Grove district. The shaft is down 40 ft. and the shoot is stated to show uniform size and content; \$4200 was obtained from the October clean-up. B. W. Pitts is owner. Seventeen mines are operating in the district tributary to Jackson. About 1600 men are employed. The monthly payroll approximates \$112,000. The Jackson and Sutter creek districts are particularly active. Jackson, December 14.

The 40-stamp mill of the South Spring mine, built in 1877 and not working during latter years, was burned on December 16.

#### ELDORADO COUNTY

Work will be resumed at the Larkin mine, and 50 men will be employed. Motors are being installed in the 10-stamp mill. The Pacific mine, owned by Baring Bros., of England, is now being worked.

#### LASSEN COUNTY

The California Gold Mining Co., which is working copper claims near Doyle, has cut a vein which carries plat-

inun worth \$140 per ton, as well as gold and copper. The vein in the shaft is from 36 to 72 in. wide.

#### SHASTA COUNTY

The Reid Mining Co. is constructing an aerial tramway one mile long to connect the mine with bins on a Southern Pacific siding on the opposite side of the Sacramento river. The cable weighs 3000 lb., and the whole will cost \$20,000. During the past four years the Reid mine has shipped ore over the Mammoth Copper company's lines to orebins at Cuargo. The new line is really a reconstruction of the Central tramway, used for many years.

#### SIERRA COUNTY

During November the 10-stamp mill of the Tightner mine, at Alleghany, produced bullion worth \$78,000. The rich ore was stoped from the lower level, 3000 ft. from the portal of the adit, and is between the old Johnson shoot and the new Red Star claim.

Hydraulic mining is under way on an extensive scale

mile. At the Aetna vein, where the principal work is being done, it is over 1700 ft. below the surface. On this vein there are many lessees, and above the 300-ft. level the Capital company has a large number of men breaking ore for its mill or the smelter at Salida. Hummer & Herber's lease is the most productive, as their ore-shoot is 150 ft. long and from 8 to 60 in. wide, from which three cars per week are shipped. About 50 tons also goes to the Combination mill at Idaho Springs. An adit has been started by the Capital company to cut the Aetna vein at 500-ft. depth, and when this is done a shaft will be sunk to connect with the Capital adit workings, 1200 ft. below. This should make ventilation better also. The property should produce \$200,000 this year.

#### LAKE COUNTY (LEADVILLE)

From the different properties of the Stars Consolidated, on Carbonate hill, shipments of different classes of ore amount to about 5000 tons per month. Lessees at the Annie have opened a large body of silicious flint on the 210-ft.

A. Y. AND MINNIE MINES, LEADVILLE.

in the western end of the county at Brandy City and Scales, the two companies operating at these points both having complied with the anti-débris regulations. The company at the former place has employed 40 men for over four years in building flumes, drains, pipe-lines, and a hydro-electric plant. San Francisco people are interested in the property. The Neocene company at Scales has been working for several years.

#### YUBA COUNTY

Argument in the water rights case of E. C. Horst Co. and others against the Tarr Mining Co. is concluded, and the matter is now under advisement. Plaintiffs assert that, from 1848 to 1910, the flow of water in the Bear river was always about 2000 in., but since 1910 the defendants have used so much from the upper reaches of the stream that crops raised near Wheatland are seriously threatened. The plaintiffs will be satisfied if 2000 in. is guaranteed them always.

#### COLORADO

##### CLEAR CREEK COUNTY

The Capital adit has been driven into Griffith mountain, from its base at the lower end of Georgetown, nearly one

level, and will make shipments. Thirty men are employed at the old Boston mine, Mayflower gulch, and a large ore-body has been opened. Mining men have recently visited the district with the object of erecting custom mills. Power has been connected to the Leadville district mill. The Iron Mask mill will be increased from 80 to 120-ton capacity, and will be equipped with new roasting furnaces, magnetic separators, and two new Wilfley tables. Lessees at the Little Giant, Dome, Rockefeller, Nevada, Little Jonny, and other properties, are busy with development and shipping ore.

#### TELLER COUNTY (CRIPPLE CREEK)

It is probable that, in the spring, a mill of 200 tons capacity, modeled on lines of the Portland, will be erected for the Midget-Bonanza company on Gold hill. St. Louis people are interested in the property. Encouraging results are reported from the 1600-ft. level of the Vindicator mine. The Portland company secured from the Denver Mint 800 new \$5 gold pieces for Christmas distribution among its employees. This custom has been kept up by the company since its organization. Lessees working on No. 4 level of the Gold King mine are shipping four cars of ore per month, averaging nearly \$40 per ton. J. C.

Clancy is leaving for New York, where he will take a place on the regular staff of the Moore Filter Company.

## IDAHO

### SHOSHONE COUNTY

Work has been started at the Tamarack & Custer Con. M. Co. The tramway, compressor, and mill are finished, and have been tried with satisfaction. Preparations are being made for erection of a mill at the Idora mine. It will consist of a crusher, rolls, elevators, concentrating tables, and jigs of the latest type, and will be of 75-ton capacity. It will be 12 miles from Wallace, and ore will be transported from the tunnel 600 ft., and then to the mill by a tramway 2000 ft. long.

The Hecla Mining Co. has paid a dividend of 5c. per share, amounting to \$50,000, making \$300,000 for 1912, and \$2,650,000 to date. The 200-ton mill of the Interstate-Callahan Mining Co. will be ready by April 1913, and will cost about \$125,000. A 450-ft. raise is being driven between the lower and intermediate levels of the mine, and high-grade silver-lead ore has been opened.

## MONTANA

### LINCOLN COUNTY

(Special Correspondence.)—The last carload of concentrate from the Snowshoe mine, which was produced during the past season, was loaded last week for shipment to East Helena. From now on, probably the only work that will be done until spring will be to keep the property clear of water and in good condition. John J. Hibbard came in from his Wolf creek placer property last Friday and has been exhibiting a piece of quartz, thickly studded with gold, which he secured while working on his claims. The quartz has the appearance of having come from a vein at some point not far from where it was found, some of the edges being quite jagged and showing but little sign of having been water washed.

Libby, December 18.

## NEVADA

### CLARK COUNTY

The Yellow Pine property, in the Good Springs district, is an interesting mine. Salt Lake and California people are interested in its development. Twelve miles of railroad was constructed to connect with the Salt Lake line. Down to the 550-ft. level the ore carries carbonate of lead and zinc, and Overstrom tables are used in the mill. About 1500 tons of zinc and 350 tons of lead concentrate are shipped monthly. Since April 1912 the company has earned \$200,000, of which \$130,000 has been paid in dividends.

### ESMERALDA COUNTY

The Darms Oil Co. will prospect the two seams of coal partly developed about four miles from Coaldale and six miles from Blair Junction, by core-drilling. The Okell driller will make a core 5 in. diam. from a depth of 1000 to 1500 ft. The seams were developed to 480 ft., showing one seam to be 3 ft. and the other 8 ft. wide. The new workings will be established about a half mile nearer the railroad, in level country.

A carload of ore has been delivered at the Goldfield sampler from the Vernal mine. The Bonnie Clare mill is treating over 1800 tons of Jumbo Extension ore per month. The ore is apparently too heavily mineralized to have over 2000 tons treated without increasing the plant. Two cars of concentrate were shipped in December to Tooele, and the average output of this product will be 125 tons per month.

### HUMBOLDT COUNTY

The Nenzei property in Rochester canyon has been incorporated under the name of the Rochester Mines Co., with a capital of \$1,250,000 in shares of \$1 each. A boom has set in at this district, and the road is crowded with teams of all kinds. Automobiles make two round trips per day from Lovelock. Two townsites have been laid out, and lots are selling fast. Twelve or fifteen lessees are

busy, and others are starting work. The National Mines Co., at National, is erecting a hoisting plant.

### MINERAL COUNTY

Drilling for copper has been started at the Lon Stewart claim, east of Mina.

### NYE COUNTY

During the week ended December 21 the mines at Tonopah treated 10,546 tons of ore worth \$212,913. The Tonopah Mining Co. treated 13,953 tons in November, yielding \$185,920 from 224,540 oz. of bullion, and \$28,975 from 80 tons of concentrate, the net profit being \$108,355. A dividend amounting to \$400,000 will be paid on January 8, 1913, bringing the grand total to \$10,050,000. The new Belmont mill treated 12,426 tons with a profit of \$195,266 from 369,422 oz. of bullion containing \$293,326 gross. On the 660-ft. level of the Extension the north vein is 10 ft. wide, of good ore. The Montana cut 2 ft. of ore on the 515-ft., 3 ft. on the 565-ft., and 3 ft. on the 615-ft. levels, all of which is profitable. At Manhattan good progress is being made with the Big Four mill. The company is treating 1000 tons of ore at the Brady mill, which should average \$20 per ton. The mine is opening well, and is being sampled throughout.

Costs of sinking the Buckeye-Belmont company's shaft at Tonopah during November follows, the average hoisting distance being 1100 feet:

	Per ft. sunk.
Timber .....	\$ 3.67
Powder .....	1.16
Electric power for .....	
Hoisting .....	1.77
Ventilating .....	0.32
Compressed air .....	1.24
Miners .....	13.56
Smiths and timbermen .....	2.17
Other labor .....	2.56
Sundry .....	2.10

Total cost per foot.....	\$28.55
Buckets of rock, water, men, etc., hoisted.....	1273
Number of sets placed.....	13
Hoisting costs per minute, cents.....	2

### STOREY COUNTY

The annual report of the Mexican Gold & Silver Mining Co. for the year ended October 31 gives the following details:

Ore treated at mill, tons .....	19,396
Ore shipped to smelter, tons.....	603
Gross value .....	\$521,495
Net returns on ore production.....	453,203
Sundry receipts .....	11,669
Total revenue .....	464,872
Average extraction in mill, per cent.....	92

#### Expenditure included:

Operating expenses (including pumping, \$107,696) ..	\$287,021
Mill construction, etc. ....	54,868
Legal, sundries, company notes, etc. ....	37,948
Supplies on hand, unsold bullion, and cash in banks ..	85,035

The 2300, 2400, and 2500-ft. levels supplied the bulk of the ore, and at present there is 4750 tons of broken ore, worth \$99,255, in the stopes and on the surface. At present stoping is being done on the 2500-ft. level. During the year the mill and cyanide plant was completed, the total cost being \$104,214, and it is now treating over 500 tons per week. The total cost of mining, milling, and treatment, exclusive of pumping, was \$8.97 per ton. Since the report, the Monte Cristo and Keyes properties have been acquired, and progress has been noted in these columns from time to time.

During the year ended November 30 the Ophir company mined 8436 tons of second-class ore, and treated at the Kinkhead mill 9495 tons, yielding \$28.40 per ton. Stored in ponds near the mill is 22,600 tons of tailing, valued at \$6.51 per ton, which is now being treated by the cyanide plant recently erected, and described in the *Mining and Scientific Press* of November 30. Jointly with the Consoli-

dated Virginia company, the 1465-ft. station of the Ophir shaft was repaired. From the 2100 and 2200-ft. levels second-class ore was mined. Work was resumed on the 2500-ft. level in April, and the southwest drift was advanced 444 ft. and is out 651 ft. to the south boundary. Quartz veins were cut, but most of the rock passed through was porphyry. At the C. & C. pumping shaft the pumps are working well at the three stations, No. 2 Reidler being under repair during the week ended December 21. The Crown Point hoisted 696 mine-cars of ore, worth \$4500, from the 1400-ft. level, the Yellow Jacket 306 cars, and Belcher 36 cars, the gross value being \$6000. Shipments to the Yellow Jacket mill were 733 tons. From the raise on the lode at 2500 ft. in the Sierra Nevada, 20 cars worth \$25 per ton were saved. The Mexican mill treated 581 tons of ore averaging \$20.10 per ton, with 92% extraction.

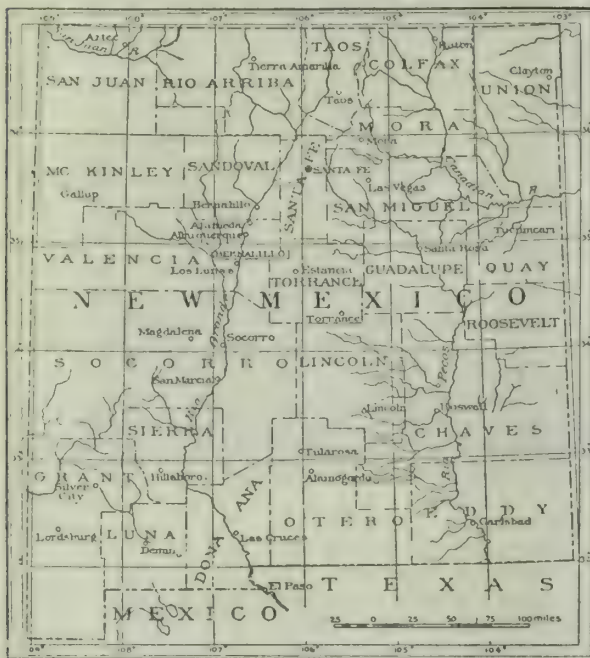

## NEW MEXICO

### GRANT COUNTY

Work on the tunnel which is to connect the Chemung Copper mine at Tyrone with the mine at Leopold is progressing with a large number of men. When the proposed shaft is sunk midway between these two places, the number of men will be increased. Mining at Fierro is active, the Colorado Fuel & Iron Co. shipping large quantities of ore daily.

### SIERRA COUNTY

The new mill at the U. S. Treasury mine at Chloride, in the Black Range district, is ready for work. It consists of Morrison crushers, which grind the ore to 100-mesh size, oversize from the screen being returned to the mill

MAP OF NEW MEXICO.

for regrinding. The machine is said to be like a tube-mill, only the quartz in the ore does its own grinding instead of using flint pebbles as is usual. Daily capacity is about 50 tons. At the mine, a shaft is down 306 ft., and development has proved a fair quantity of silicious ore, with a little sulphide and carrying gold and silver.

High-grade ore is being shipped from the Silver Monument to smelters. The old workings have been opened by an adit 1500 ft. long, but the best orebodies are below this adit. A large tonnage of low-grade ore has also been opened.

### SOCORRO COUNTY

(Special Correspondence.)—During the week ended December 13, 745 tons of ore was treated at the Ernestine mill, producing 57 sacks of high-grade concentrate. The third 10-day clean-up of November yielded 9350 oz. of

bullion and 4.2 tons of concentrate. The electric hoist at the Little Charlie mine of the Mogollon company is working well and hauling 40 tons per day. From The Oaks Co. regular shipments are being made to custom mills. Development in the lower levels of the Deadwood mines is opening good ore. The Socorro mill treated 1100 tons during the week. The Trilby and Apache groups are being developed, the former's 200-ft. level being in ore.

Mogollon, December 13.

## OREGON

### BAKER COUNTY

It is stated that the Standard mine, near Prairie City, will be again worked by the Utah Copper Co. Several years ago 100 men were employed. There is a complete mill on the property, which has not been worked for some years and recently was the subject of several lawsuits.

## UTAH

### JUAB COUNTY

At the Victoria mine electric power is used on the hoist, and the new compressor is being installed. A recent ore shipment of 60 tons brought a settlement of \$60 per ton. The Lower Mammoth is mining good zinc ore at the 1500 and 1600-ft. levels, and in the west drift of the former level 15% ore has been opened which, while not profitable, is of importance in development. From the Grand Central mine about 100 tons of ore, worth \$200 per ton, was sent out, while 100 tons of copper ore will average about \$65 per ton. A prospecting winze is being sunk from the 700-ft. level of the Opohongo mine. Four cars of ore are shipped each week. On December 18 the Eagle & Blue Bell company hoisted 175 tons of shipping ore from the 700 to 1350-ft. levels, and the average quantity for the week was 150 tons per day.

### SALT LAKE COUNTY

The Ohio Copper Mining Co. made a net profit of \$32,500 in November. On one day last week the two units of the mill dealt with 2400 tons of ore. The work of removing the Wall rolls from No. 2 section is not completed yet.

### TOOELE COUNTY

W. Wraith, who has been with the Anaconda company for seventeen years, during the past nine years as superintendent of the Washoe reduction works, has been appointed general manager for the International Smelting & Refining Co. At present the company is not working its copper smelter owing to scarcity of ore. Two lead furnaces are working, and two new ones will be ready within six weeks.

## WASHINGTON

### STEVENS COUNTY

The Arcade Mining Co., of Chewelah, will be reorganized and the capital increased from 500,000 to 1,500,000 shares of \$1 each. Machinery will be installed at the mine, and as soon as a depth of 200 ft. is reached ore will be stoped for shipment. The first diamond-drill exploration in this district will be started in January by the International Diamond Drill Co., which will drill several thousand feet in the claims of the United Copper and Aurora Copper Mining companies. Some high-grade copper ore has been mined from the 120-ft. level of the High Grade mine, near Chewelah. It is mainly a black oxide of copper carrying silver.

## BRAZIL

From March to August, 1912, the St. John del Rey mill treated 91,958 tons of ore worth \$1,070,000, a decrease of 4642 tons compared with the same period of 1911, but the yield was 38c. per ton higher. Profit amounted to \$350,000. Labor has been scarce owing to railroad and municipal work in progress. The mine is showing good results, the lowest, No. 17, horizon showing a length of 1028 ft. of ore, 12.5 ft. wide. A dividend of 18c. per share was paid.

Iron and steel men on or near the Atlantic coast are much

interested in some negotiations now in progress in London, attention being focused upon the Itabira Iron Ore Co., Ltd. This company, which is an English corporation, holds certain concessions covering three properties in the district of Itabira, in the province of Minas Geraes, Brazil. It is understood that there is now being formed a corporation with a capital of \$100,000,000 by financiers of the continent and of London, including the Rothschilds, the Barings, Sir Ernest Cassel, and a group of American bankers whose identity is not yet revealed.

## CANADA

### BRITISH COLUMBIA

The Granby company has closed contracts worth \$700,000 for equipment at its Hidden Creek mines, Granby bay. The Pelton Water Wheel Co. received a contract for water wheels; Traylor company, the furnaces, converters, settlers, crushers, and sampling machinery; Connorsville Blower Co., the blowers; Nordberg company, the compressor plant; Hallidie company, the traveling cranes, etc.; Brown Hoisting Machinery Co., hoisting apparatus; and the Westinghouse Electric & Manufacturing Co., rolling stock, consisting of two 43-ton, six 12-ton, and eight 6-ton electric locomotives and twenty-five 25-ton steel ore-cars. At the Hidden Creek mines diamond-drilling has proved better than expected. The Grand Forks smelter treated 1,263,000 tons of ore from the mines at Phoenix during 1912, yielding 22,650,000 lb. of blister copper, 356,376 oz. of silver, and 52,359 oz. of gold, at a cost of \$2.38 per ton for mining and treatment.

### COBALT

During the week ended December 13, nine mines shipped 533 tons of ore, and the Nipissing company sent out 49,679 oz. of bullion. The Hudson Bay Mining Co. paid \$23,283 in dividends on December 20. During November the Nipissing washing plant was not working all the time, but is now treating from 250 to 300 tons per day. Hydraulic work was discontinued on November 30 owing to cold weather. The high-grade mill treated 134 tons of ore worth \$168,707. In the low-grade mill 10 to 15 stamps were started during the month.

### PORCUPINE

The Swastika main shaft is down 400 ft., and 12 ft. of ore worth \$15 per ton has been cut. Enough ore has been developed on No. 1, 2, and 3 levels to keep the mill busy for two years. The final shipment of machinery for the mill has reached the mine. At the McIntyre, 25 men are working on the new mill. The old 10-stamp mill is crushing ore from the dump at No. 2 shaft. Fifty men are busy on the pipe-line from Porcupine lake to the Dome mine, which will supply water during the winter. In connection with the strike, two special cars of 50 and 60 strike-breakers arrived for the Hollinger and Dome mines, respectively. They were not molested. There seems to be no chance of the mine-owners and strikers coming to an agreement.

## MEXICO

### CHIHUAHUA

The Federal army in this state numbers over 11,000 men, and the rebels number about 3000, as against 12,000 when Orozco was personally directing the campaign. The Banca de Sonora, at Alamos, Sonora, received on December 10 bullion worth \$180,000 from the Rio Plata Mining Co., situated in the Arteaga district of western Chihuahua. This consignment was carried on burros and was not molested on the five days' journey.

### JALISCO

Jose Martinez and Jose Castanos, who were in command of the rebels near Juanacatlan, in this state, have surrendered. Other rebels are said by Portillo y Rojas, the governor, to be leaving Jalisco, in view of the fact that the inhabitants in many parts of the state have taken arms against the lawless and are fighting them wherever they are found.

### SONORA

In expectation of trouble among the Mexican miners em-

ployed by the Greene-Cananea Copper Co., all saloons have been closed and the garrison of Federal troops increased by 150 men. On December 18 750 Mexican miners struck work on refusal of the companies to grant an increase of 25% in wages and an eight-hour day instead of nine. Later on the Cananea Consolidated company offered to reduce the hours to eight and a half, effective January 1, 1913.

The United States Graphite Co., owner of Lapiz mine at La Colorada, is shipping three carloads of graphite per week to Saginaw, Michigan. The San Xavier mines have between 3000 and 4000 tons of ore on the dumps which cannot be moved on account of lack of freighters. The Yaqui Indians are causing so much trouble in that district that it is impossible to get men to haul this ore out. The cyanide plant of the Creston Colorado, at Torres, is treating 350 tons per day.

At El Tigre, during November, the old mill crushed 2667 tons of ore, the stamp-mill crushed 3207 tons, while the cyanide plant treated 5658 tons of current and 1649 tons of dump tailing. From ore shipped, concentrate, and cyanide plant, the total yield was \$139,567. Costs, including freight, smelter, and taxes, were \$81,415, leaving profits at \$58,152.

## Universities and Mining Schools

The UNIVERSITY OF IDAHO, Moscow, will offer courses similar to those given to miners and prospectors at the University of Washington, at a winter session opening January 5. The courses include surveying, laboratory work, mining, treatment of ores, and bookkeeping.

THE UNIVERSITY OF WASHINGTON, Seattle, will begin a three months' mining session on January 7. This course of instruction in mining, metallurgy, and related subjects is open to everybody without any restrictions in regard to previous training or experience. To the prospector who wishes to learn something which may be of value to him in his useful work, this opportunity to spend three months in the laboratories of the university is now offered. The work is arranged to suit the needs of the individual, and no charges are made for instruction, save that students buy their own books and supplies. Board and lodging may be secured close by at a moderate cost.

THE UNIVERSITY OF WISCONSIN is now giving instruction by correspondence in many engineering studies, including 16 courses in electrical engineering, 8 in mechanical drawing, 24 in mechanical engineering, and 16 in structural engineering. Instruction by correspondence is also given in many other subjects of importance to engineers, such as mathematics, chemistry, geology, and mineralogy. These courses include subjects which are usually given chiefly by lectures and recitations, and others which are largely laboratory work, such as shop sketching and topographic surveying. Recently a course has been added in microscopic petrography, given by A. N. Winchell, and in connection with work in mineralogy and economic geology as previously given, this should be of special value.

THE MASSACHUSETTS INSTITUTE OF TECHNOLOGY, in its bulletin for December, gives full details of everything in connection with the school. In the department of mining engineering and metallurgy are nine instructors, who give lectures and superintend laboratory work and the summer school. The work presupposes that the preparatory courses in mineralogy, geology, and surveying, given in preceding years, have been taken. Second year's work with lectures on mining engineering and metallurgy, is followed in the third year by lectures on mining methods generally. Ore dressing in the fourth year is taught by lectures and extended laboratory work. The student is given a wide experience in actual metallurgical work and checks his results by assays and chemical analyses at appropriate stages of the process. Applicants for admission to the Institute of Technology are, in general, required to pass the entrance examinations. Tuition fee for regular courses is \$250 per year. Examinations are held each year in January and May. The second term of the year 1913-14 commences on February 9.

## Personal

Professional men are invited to send news of their engagements and travels. Such news is interesting to friends.

HENRY HANSEN is in town.  
L. C. TRENT is at the Palace.  
F. H. DAKIN, Jr., is in town.  
H. H. WEBB has gone to the Rand.  
GEORGE KINGDON was in Bisbee recently.  
L. I. ROWLAND is at Oakland, California.  
J. G. FOLLANSBEE was at El Paso recently.  
C. J. EGELSTON has gone to Salt Lake City.  
EDMUND JUESSEN has returned from Colorado.  
C. E. JAMISON has gone East for a brief stay.  
M. FARRAGGI has returned to Europe from Peru.  
C. R. CORNING has gone to Europe for six weeks.  
R. P. F. PRAIN was at Buenos Aires last month.  
D. W. SHANKS was in San Francisco and has gone to New York.

JACOB W. YOUNG, of Marysville, Utah, has moved to Philadelphia.

WILLIAM A. KRIPPACHUE has gone to Seattle from Cordova, Alaska.

WILLIAM B. PHILLIPS is operating a silver-lead mine near Alpine, Texas.

M. H. KURLA was married on December 21 and has gone to Mexico.

J. W. METZGAR is manager for the Goldfield Merger Mines Company.

W. F. DEANER, manager for the Original Amador mine, is in San Francisco.

WILLIAM R. JEWELL has returned to Bakersfield from examination work in Utah.

C. H. KREMERS is now engineer for the Mammoth smelter, at Kennet, California.

W. H. CASE has returned to El Paso from examination work at Courtland, Arizona.

R. FYFE KERR, general manager for the Guadalupe y Calvo mines, is at the property.

W. H. PAUL, formerly superintendent of the Dolores mine, in Chihuahua, is now at Denver.

L. F. S. HOLLAND will return to Telluride, Colorado, on January 1, from Arizona and Nova Scotia.

PRICE MCKUMEY and JAMES W. CORRIGAN paid a recent visit to the Coneheno mine in western Chihuahua.

B. C. JACKSON, who was formerly with the Caribbean Petroleum Co., at Caracas, Venezuela, is now at Los Angeles.

RALPH B. WILLIAMS, formerly of El Paso, Texas, is now with the Minas Dolores y Anexas, Matehuala, San Luis Potosi, Mexico.

GELASIO CAETANI will deliver a course of lectures at Harvard University early in February, after which he will go to Europe for a brief stay.

WILLIAM WRAITH has been made general manager for the International Smelting & Refining Co., and will remove to Salt Lake City from Anaconda on January 1.

## Obituary

ROSWELL E. SAMPSON, assistant professor of metallurgy in the State College of Washington, at Pullman, was struck and instantly killed by a Northern Pacific train on the morning of December 12. Mr. Sampson was a native of Medford, Massachusetts, and a graduate of the Massachusetts Institute of Technology, class of 1907. His first professional work was that of assayer and surveyor for the Marietta Mines Co., near Mina, Nevada, after which he was engaged in ore-testing work for the Huff Electrostatic Separator Co. of Boston. He next joined the engineering staff of the Quincy mine at Hancock, Michigan, and later became assistant to his former teacher, R. H. Richards, in adapting the Richards classifiers to Quincy mill conditions. He joined the mining faculty of the State College of Washington in the fall of 1911.

## Market Reports

### LOCAL METAL PRICES

San Francisco December 26.

Antimony .....	12-12½c	Quicksilver (flask) .....	89

James Lewis & Son's Copper Report

During November the price of standard copper has moved in accordance with the varying prospects of an early peace being concluded between the Balkan states and Turkey, and with the fear of intervention.

From £75 7s. 6d. on November 1, cash prices advanced to £76 7s. 6d. on November 8, but declined to £76 on receipt of the American refiners' statistics on November 11, recovering to £78 10s. on November 18, from which point there was a gradual drop to £76 7s. 6d. on November 26. Changes since have been small, between £77 2s. 6d. and £76 7s. 6d., closing prices on December 2 being £76 17s. 6d. for cash and £77 12s. 6d. for three months prompt. Sales totaled about 35,000 tons. There was only a moderate demand for refined copper, and that was chiefly for early delivery, the quantity available being limited. Japanese electrolytic sold at £80 15s. per ton c.i.f. for January delivery, but for American £82 was asked, larger producers holding for 17¾c. per pound, at which price a fair quantity has been sold for home consumption, and a moderate for export. Manufactured has been in fair request.

American shipments during November were advised as only 19,146 tons. As production for that month is not likely to show any relative reduction on October, and as the large deliveries for home consumption during that month are stated to be due to pressure to ship Lake copper before the close of navigation, an increase of about 10,000 tons in refiners' stocks appears probable. European stocks have decreased 4085 tons, and the visible supply 3060 tons during November. Imports were 1844 and deliveries 9092 tons less than during the same month of 1911. Total arrivals in England and France were 13,108 and deliveries 16,717 tons fine, and from other countries 8712 and 10,127 tons respectively. Arrivals at Liverpool and Swansea from the United States were 1175 tons of bars and 260 tons of ingots, equal to about 1432 tons fine; in London, 250; and in France 2459 tons fine. Chile charters for the month were advised as 2150 tons, including 550 tons for the United States. Quotations December 2 were: Standard, £76 17s. 6d. for cash, and £77 12s. 6d. for three months prompt; English best selected ingots £82 15s. to £83 5s.; and tough cake, £82 10s. to £83 per ton, less 2½% delivered at Birmingham. Electrolytic wire bars, £81 10s. to £82 net cash c.i.f.; 13s. 9d. to 14s. for ore of 20%, and 14s. to 14s. 3d. per unit for Chile regulus, or American silver-free matte.

India as a Precious-Metal Market

Some interesting figures are made available in the joint report compiled by the Bureau of the Mint and the U. S. Geological Survey, covering gold and silver production in 1911 and 1910. The gold produced in the United States in 1911 was 4,687,053 oz., valued at \$96,890,000. This is an increase of about 30,000 oz. over the output of 1910 and a decrease of 134,000 oz. under the output of 1909, when the production was 4,821,701 oz., valued at \$99,673,400. In connection with the precious-metal production of the world, the position of India continues to attract attention. India has been for so many years looked upon as a steady absorber of silver that it is not to be wondered at that its turning into a hoarder of gold would upset the calculations of the economists. The reason why the absorption of gold by India is a particularly disturbing feature compared with its absorption by any other nation of the world, is that of the gold shipped to India 90% or more is withdrawn from circulation, nor has it any representative medium to pass from hand to hand in commerce. Instead, it is hoarded in such a way as to be almost as completely locked up as when it was in its primeval condition underground. It is pointed out that in the past five years India has absorbed 12% of the total output of gold, and that this absorption is increasing. As against a taking of 11.62% in 1907, India took to hoard away and to make into bracelets and anklets, 16⅓% of last year's output. It is difficult for the commercial nations of the world to realize that India can become to so large an extent a creditor nation. Especially is this true when the credit so held is in the form of hoarded metal instead of bills of exchange or book balances, or in any of the usual forms of international debits and credits. There is a most interesting field for speculation opened in this way in regard to the increase in commodity prices and the so-called problem of the high cost of living.

Growth of the Copper Industry

The copper industry in the United States has shown a notable growth, according to the United States Geological Survey. In 1845, when important production of copper in this country practically began, the output was but 224,000 lb., but it increased 100% the following year and gained by rapid strides until 1850, when the production was 1,456,000 lb. In 1870 it was 28,224,000 lb.; and in 1890 it was 259,763,092 lb.; in 1900 it had increased to 606,117,166 lb.; in 1909 it passed the billion mark, with 1,092,951,624 lb.; and in 1911 it exceeded all previous records with a production of 1,097,232,749 lb. The world's production in 1911 was 1,958,201,285 lb., of which 56% was the output of the United States.

It is noteworthy that, unlike areas producing most other metals, not one of the leading copper districts of the United States, several of which have been active producers for a period of 30 years or more, has been worked out or showed a marked decrease in its ability to produce copper. Twelve districts situated in eight states have each contributed over 100,000,000 lb. to the copper output of the country, or a total of 94% of the whole output of the United States since 1845. Four of these districts are in Arizona, two in California, and one each in Montana, Michigan, Nevada, New Mexico, Tennessee, and Utah. Two districts stand out prominently, the Butte district, Montana, which has contributed over one-third of the output of the country, and the Lake Superior district, Michigan, with a production of a little less than one-third of the total output.

Arizona ranks first among the United States in the mining of copper, according to the United States Geological Survey. It ranks sixth in the production of silver and seventh in the production of gold. These three metals constitute 98% of the total production of the state, which amounted to \$43,483,912 in 1910 and \$44,104,731 in 1911. The value of the copper product alone represents 86% of the total output.

## Book Reviews

Any of the books noticed in this column are for sale by, or can be procured from, the MINING AND SCIENTIFIC PRESS.

INDEX OF MINING ENGINEERING LITERATURE. By W. R. Crane. 445 pp.; index. John Wiley & Sons, New York, 1912. For sale by the *Mining and Scientific Press*. Price \$3.

A work of this description is useful to those who find it necessary to refer to important articles published in technical journals, such as in an editorial office, contributors to such journals, or others in search of information. It may be considered up to date at the time of publication, after which it must be supplemented by one of the indexes published regularly by one of the well known journals or societies. This volume is carefully prepared, well arranged, and generally represents a great deal of labor on the part of the author, though only a rather limited number of publications have been indexed.

HANDBOOK OF MINING DETAILS. Compiled from the *Engineering and Mining Journal* by the editorial staff. 372 pp.; ill. McGraw-Hill Book Co., New York, 1912. For sale by the *Mining and Scientific Press*. Price \$4.

Nothing is more interesting and useful than a well made scrap-book. For some time it has been the custom of the *Engineering and Mining Journal* to devote a few pages to short notes on details of practical work, either contributed by readers or prepared by the staff. In the course of time an enormous amount of material has thus accumulated, and a judicious selection of the best of this is here gathered together in convenient form for reference. Practically the whole field of mining work is thus covered; metallurgy is not touched upon. Numerous illustrations and a good index contribute not a little to the value of this excellent book, which is likely to prove one of the most popular books of the year. The price asked is unnecessarily high, since compilations such as this can be issued at small expense, but doubtless engineers will generally feel that it is well worth the money.

HIGH SCHOOL GEOGRAPHY. By Charles R. Dryer. 535 pp.; ill. American Book Co., New York, 1912. For sale by the *Mining and Scientific Press*. Price \$1.30.

The study of geography exhibits perhaps to a higher degree than any other topic the enormous progress made in the presentation of scientific knowledge. Men who are still in their first youth can remember the folio volumes illustrated by crude and often inaccurate regional maps, and replete with poorly presented material of not unimpeachable accuracy, the efforts of teacher and scholar being concentrated upon the mastery of the boundaries of states and kingdoms, political features frequently of zero significance from a geographical standpoint. Even a hasty perusal of such a volume as this is stimulating by contrast. The physical factors which condition the topographical features are logically considered first, followed by the economical factors which are their result. Topography is considered last. The up-to-date character of the book is indicated by the map of Asia, where the Chinese Republic is so designated. It is good to know that young people now have books of this character to serve as texts, and those who belong to an earlier generation will welcome the opportunity to revise their knowledge of the subject which is the basis no less of ancient history than of modern life and commerce.

## Concentrates

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

**'GOAVE'** is a term used to signify broken ground, or the parts of a mine from which the coal or ore has been worked.

**FILLING** stopes with old sand or slime from dumps has been done at a cost of only 5c. per ton in some mines in Western Australia.

**AMALGAMATION** is not practised in any way in the treatment of Tonopah ores, nor is acid treatment necessary in clean-up operations.

**SLIME** in treatment mills generally gives better results if as much valuable solution as possible is decanted or got rid of before filtering.

**CHAIN** driving tube-mills, pumps, or other machinery has proved successful at Tonopah, and is thoroughly reliable, with low power losses.

**HOISTING** ropes of 3½-in. width are used at several mines in Nevada, but they require a good deal of attention, especially after 12 months' use.

**ORE** fed to stamps, in many cases, is not directly sampled, but the value is calculated from tailing assays, concentrate content, and bullion actually recovered.

**Oxalic acid**, in Norway, is successfully manufactured from sawdust. In Victoria, Australia, several useful compounds are being made from the distillation of wood.

**MORTAR-BOXES** have been set on heavy sheet lead in some districts, but this seems to get beaten out unevenly, and the usual sheet of rubber has been substituted for it.

**WASTE** from sorting belts is usually trammed to dumps in cars. At the new Belmont mill, at Tonopah, where about 15% is picked out, a slow-running belt-conveyor discharges it upon the dump.

**BULLION** produced in the Tonopah mills averages about 950 fine in silver and 12 in gold. The bars are sampled by drilling a hole about ½ in. deep at opposite corners of the top and bottom.

**PIPES** connected with pumps and tanks in mills situated in cold climates should be so arranged that they can be drained after use, especially where used in intermittent work, such as in vacuum filtration of slime.

**MOTOR** drive for the cam-shafts at the Homestake mills consists of one 25-hp. motor for each 10 stamps, set at about the level of the cam-shaft and 20 to 25 ft. distant, transmitting power by a 16-in. double leather belt.

**MINTS** of the United States during October coined 26,672,261 pieces, valued at \$510,092.58. One cent pieces totaled 22,880,108; and 5-cent, 3,200,035; while for the Philippine Islands' Government there were 356,000 peso pieces and 520,000 10-centavo pieces coined.

**LOSSES** of heat by uncovered steam-pipes are not only high, but wasteful. To offset the heat from a bare 4-in. pipe-line, 300 ft. long, carrying steam at 125 lb. pressure, with the temperature of the air 90°F., it has been calculated that the consumption of 105 tons of coal per year would be necessary.

**TUBE-MILLS** half filled with pebbles generally give best efficiency in grinding and power consumption. It was found at the West End mill, at Tonopah, that when filled 6 in. above the centre line, motor readings were abnormally high, but on further filling the power did not rise to any extent.

**ESSENTIAL** factor in successful treatment of ores by flotation is the obtaining of a thick substantial or 'matted' froth, necessary to support the coarser mineral particles. If, through lack of observance of certain simple conditions, it is allowed to become thin and skin-like, it will not afford the same chance for retaining these.

**VARIOUS** devices have been tried in order to get better amalgamation on copper plates, the latest being a screen fixed a few inches above the plates which breaks the flow of pulp from stamps and lets it shower upon, instead of flowing over, the plates, thereby arresting the flow momentarily and giving better contact.

**STAMPS**, numbering 1000, crush 125,000 tons per month at the Homestake mine, South Dakota. Of this, 57% goes to the sand and 41% to the slime plant, between 1 and 2% of the slime being wasted. Of the total gold content, 94% is recovered, about 72% as amalgam and 22% by the cyanide process. From an ore carrying about 0.2 oz. gold per ton, the total monthly recovery is nearly \$500,000.

**GOLD** varies in color according to the amount of silver alloyed with it, and may range from pale yellow to full gold color. Gold alloys are made more reddish by the presence of copper, and by varying the relative amount of silver and copper in the gold, any desired shade may be obtained from 'Roman gold' to a pale yellow. The presence of impurities may cause gold to show a variety of colors on a tarnished surface.

**FINE** grained precipitates such as BaSO<sub>4</sub>, which tend to run through filter-paper, can be restrained in the following simple way. Take a small ashless paper, tear it into minute fragments, and shake well with a little warm water in a test-tube, until a pulp is formed. This pulp is added to BaSO<sub>4</sub> precipitation, stir well, allow to settle for a few minutes, and then filter. Do not add too much pulp, or it will be difficult to wash the precipitate thoroughly.

**MANGANESE** is chiefly used in the form of alloys in the steel industry, or as oxide in chemical industries. Ores to be used for the first purpose should be as low in SiO<sub>2</sub> as possible, while for the second they must be free from iron. Sometimes the quality of the ore can be improved by ore dressing methods. Russia is the principal producer of manganese, followed by India and Brazil. Most of the high-grade ore used in the United States is imported; imports in 1911 amounting to 177,000 tons, valued at \$1,187,000, and domestic production 634,000 tons, valued at \$1,386,000. The deposits of the United States are described at length in Bulletin 427 of the United States Geological Survey.

**LITHIUM CARBONATE** is chiefly used in the manufacture of artificial lithia waters and for medicine. Eminent physicians have claimed that it has a solvent effect upon uric acid, the deposit of which in the blood gives rise to certain diseases. Equally eminent physicians, however, have recently claimed that it does not possess such solvent power. The question is therefore an open one. Small amounts of the carbonate are used in the manufacture of fire works. The hydroxide is used mainly in storage batteries of the Edison type, in connection with alkaline electrodes, in which the depolarizing electrode consists of an oxygen compound of nickel, whereby the capacity of the battery is increased and the life of the cell prolonged. The chloride and bromide of lithium are used in photography and in medicines. Spodumene when occurring fresh and glassy with an emerald green color sells for high prices as a gem.

## Decisions Relating to Mining

Specially reported for the MINING AND SCIENTIFIC PRESS.

### AMENDED LOCATION NOT EVIDENCE OF ABANDONMENT

Where a locator had made a prior location of certain mining claims in Summit county, Colorado, upon which adverse locations were subsequently made, and after said adverse locations were made the original locator elected to amend his former location by sinking new discovery shafts and filing new location certificates to correct previous errors, it was held that the making of such an amended location did not constitute an abandonment of his rights under the first location such as would enable the adverse locator's rights to attach. An abandonment of a mining claim is a question of fact to be found from the intention.

King Solomon Tunnel, etc., Co. v. Mary Verna Mining Co., (Colorado) 127 Pacific, 129. October 14, 1912.

### COAL LANDS—ACQUISITION AND PURCHASE OF

The projection of underground workings from a tract of privately owned ground into an adjoining tract of public land, with a view to extracting the coal therefrom, such being the only feasible and practical method of opening up and mining the coal from such adjoining tract, followed immediately by the execution and filing of a declaratory statement, giving notice of the extent of the coal lands claimed, constitutes the opening of the coal land laws. The expenditure of \$5000 required by Section 2438, Revised Statutes, to be made by an association of four or more qualified persons seeking to acquire title to 640 acres of coal lands on condition precedent to the right to enter, but not to the right to file a declaratory statement. Where the tract in question was re-appraised after the opening and improving of a mine and the filing of the declaratory statement, but prior to the expenditure of \$5000 required as above, the claimant upon seasonably making the required expenditure, is entitled to purchase at the price existent at the date of opening and improving the mine of coal.

Carthage Fuel Co., (New Mexico) 41 Land Decisions, 21. May 21, 1912.

### MINERAL RIGHTS DECISION—BASIS OF JUDGMENT

The State Supreme Court of Texas in a recent decision holds that the statute reserving to the state the mineral rights in its public land, which are commonly known as school lands, is constitutional. The case was that of A. A. Cox v. J. T. Robison, Commissioner of the General Land Office. Two members of the Board joined in the opinion, the other member, J. B. Dibrell, Associate Justice, not concurring.

In this particular case Mr. Cox sought to obtain an unconditional patent to eighty acres of land in Culberson county, which he had bought as grazing land. The Land Commissioner refused to patent it without a reservation of the mineral rights to the state under Article 3498. It was contended by Mr. Cox that the state should give an unconditional patent because the article under which the Commissioner acted is in conflict with and contrary to Section 7 of Article XIV of the Constitution, which reads: "The state of Texas hereby releases to the owner or owners of the soil all mines and minerals that be on same, subject to taxation as other property."

Nelson W. Phillips, Associate Justice, wrote the opinion for the court. He recalled that the mining industry is only in its infancy in Texas. He went back to the constitutional convention of 1866 and found the release provision there with regard to mineral rights. He investigated and found that this provision provided only for the release of rights on certain property which had already been disposed of; that the intent of the convention in 1866 in releasing certain mineral rights was not to apply the provision to all future sales, but to past disposition of real estate.

D. Phillips, Judge, says that it is recognized that in general constitutional provisions are construed as prospect-

ive, but the exception is well established that they may operate retroactively when it is apparent that such was the intention. He finds that when the provision was first read into the constitution there was no intention to make the release provision apply to all future grants from the state and that it would be illogical to assume that those who came after in writing constitutions of the state had this intention and desired to change the organic law by reenacting an old provision. He also found that since 1863 the legislature has provided for the reservation of mineral rights to the state and it seems to be a fixed policy from the time that the constitution of 1866 was written.

## Thibault Gold Amalgamator

In this device the gold is brought in contact with quicksilver by inverting an amalgamated copper plate and placing it nearly horizontally upon the surface of a shallow body of quicksilver. The gold-bearing material passes through an elongated spout (Fig. 1 and 2) under the amalgamated plate (Fig. 4), and over the surface of the quicksilver, then upward through a tortuous passage lined with amalgamated copper to the spillway. The sand or gritty material in passing creates a scouring action upon the quicksilver surfaces, keeping them bright and clean. Ribs extending below the surface of the quicksilver and integral with the plate prevent diagonal currents and present a greater amalgamating surface to the stream by attract-

ing the quicksilver upward along their surfaces. The stream before leaving the amalgamator takes an upward course, first coming in contact with one amalgamated lining and then with the amalgamated copper partition, which directs it toward the spillway. This partition also serves to hold down the free end of the plate when working. It is held in place by pins through the side walls; a lock can be inserted through the point of the pin, if desired, to prevent unauthorized persons from lifting the plate and removing the gold amalgam from within. A locking device is also provided on the drain cock. The plate, being hinged to the spout portion, can be raised for inspection, or if it needs dressing it can be lifted from its hinges (the hinge is so constructed as to release when the plate is in a raised position; this feature is not shown in the cut) and another or extra one can be inserted in its place, delaying operation only during the time necessary to change plates. The plate dressing can be done later in a clean-up room. The riffled portion (Fig. 5) is placed under the spillway to recover any particles of quicksilver which might accidentally pass over the spillway. This amalgamator is designed to treat fine material, and it is necessary to screen out the coarse sand and gravel before it enters the hopper. The 24-in. amalgamator is claimed to be capable of handling 1½ tons of screened sand per hour. It is made by E. E. Thibault, 1178 Union street, San Francisco.
